Docket Nos. CP06-365-000 and
CP06-366-000

FERC/EIS-0214F

TO THE PARTY ADDRESSED:

The staff of the Federal Energy Regulatory Commission (FERC or Commission) has prepared this final Environmental Impact Statement (EIS) for the construction and operation of the liquefied natural gas (LNG) import terminal and natural gas pipeline facilities, referred to as the Bradwood Landing Project, proposed by Bradwood Landing LLC and NorthernStar Energy LLC (collectively referred to as NorthernStar) in the above-referenced dockets. The Bradwood Landing Project facilities would be located in Clatsop and Columbia Counties, Oregon, and Cowlitz County, Washington.

This final EIS was prepared to satisfy the requirements of the National Environmental Policy Act (NEPA). The U.S. Department of the Army Corps of Engineers (COE), U.S. Department of Homeland Security Coast Guard (Coast Guard), and the Pipeline and Hazardous Materials Safety Administration of the U.S. Department of Transportation (DOT) are cooperating agencies for the development of the EIS. A cooperating agency has jurisdiction by law or special expertise with respect to potential environmental impacts associated with the proposal and is involved in the NEPA analysis.

Based on the analysis included in the EIS, the FERC staff concludes that the proposed action would have limited adverse environmental impacts. However, if the Bradwood Landing Project is constructed and operated in accordance with applicable laws and regulations, and with implementation of NorthernStar's proposed mitigation measures, and the additional mitigation measures recommended by staff, environmental impacts would be substantially reduced.

The purpose of the Bradwood Landing Project is to provide a new source of natural gas to the Pacific Northwest through importing LNG. LNG is natural gas that has been turned into a liquid state by cooling it to about -260 degrees Fahrenheit to reduce its volume for transport in specially designed carriers some distance across oceans from its point of origin to the proposed LNG import terminal. NorthernStar would store the LNG at its terminal, vaporize the LNG back into natural gas, and provide up to 1.3 billion cubic feet per day of natural gas to the region through its sendout pipeline and interconnects at two industrial facilities, an intrastate pipeline, and an interstate pipeline system.

The EIS addresses the potential environmental effects associated with the construction and operation of the following facilities located at the proposed Bradwood Landing LNG terminal, at Columbia River Mile 38, in Clatsop County, Oregon:

- a 58-acre maneuvering area off the federally-maintained Columbia River navigation channel, and a single berth capable of receiving and unloading LNG carriers with cargo capacities ranging from 100,000 to 200,000 cubic meters (m³);
- a set of four 16-inch-diameter LNG unloading arms at the berth, and a 1,240-foot-long 32-inch-diameter cryogenic LNG transfer pipeline and 6-inch-diameter LNG recirculation cooldown pipeline from the berth to the storage tanks;
- two 160,000 m³ insulated LNG storage tanks;
- a vapor handling system and vaporization equipment, including seven submerged combustion vaporizers capable of regasifying the LNG for sendout through a transfer meter station; and
- ancillary utilities, service buildings, and associated safety and security systems.

The EIS also addresses the potential environmental effects associated with the construction and operation of NorthernStar's proposed sendout pipeline and associated facilities, including:

- a 36.3-mile-long underground, high-pressure steel sendout pipeline consisting of approximately 18.9 miles of 36-inch-diameter pipeline in Clatsop and Columbia Counties, Oregon and 17.4 miles of 30-inch-diameter pipeline in Columbia County, Oregon and Cowlitz County, Washington; and
- associated facilities, including five meter and regulation stations, four interconnects, two pig¹ launchers, and two pig receivers.

The final EIS has been placed in the public files of the FERC and is available for distribution and public inspection at:

Federal Energy Regulatory Commission
Public Reference Room
888 First Street N.E., Room 2A
Washington, DC 20426
(202) 502-8371

Only volume 1 of the final EIS, containing text of the analysis, was printed in hard copy. Volume 2, containing the appendices, was produced as .pdf files on a compact disk (CD) that can be read by a computer with a CD-ROM drive. A limited number of hard copies and CDs of the final EIS are available from the FERC's Public Reference Room, identified above. This final

¹ A pig is an internal tool used to clean and dry a pipeline and/or to inspect it for damage or corrosion.

EIS is also available for public viewing on the FERC's Internet website at www.ferc.gov, via the eLibrary link.

Copies of the final EIS have been mailed to federal, state, and local agencies; elected officials; Indian tribes and Native American organizations with an interest in the project area; interveners; regional environmental organizations and public interest groups; affected landowners; local libraries and newspapers; and other interested parties. Hard copies of volume 1 were mailed to those who specifically requested them, while all others on the mailing list were sent both volumes of the EIS on CDs.

Additional information about the project is available from the Commission's Office of External Affairs at **1-866-208-FERC** (3372). The administrative public record for this proceeding to date is on the FERC Internet website (<http://www.ferc.gov>). Go to Documents & Filings and choose the eLibrary link. Under eLibrary, click on "General Search," and enter the docket number excluding the last three digits in the Docket Number field (e.g., CP06-365). Be sure you have selected an appropriate date range. For assistance, please contact FERC Online Support at: FERCOnlineSupport@ferc.gov or toll free at 1-866-208-3676, or for TTY call 202-502-8659. The eLibrary link on the FERC Internet website also provides access to the texts of formal documents issued by the Commission, such as orders, notices, and rulemakings.

In addition, the Commission now offers a free service called eSubscription that allows you to keep track of all formal issuances and submittals in specific dockets. This can reduce the amount of time you spend researching proceedings by automatically providing you with notification of these filings, document summaries, and direct links to the documents. To register for this service, go to the eSubscription link on the FERC Internet website (<http://www.ferc.gov/docs-filing/esubscription.asp>).

APPENDIX B	PIPELINE LOCATION MAPS
APPENDIX C	SHORELINE MAPS INCLUDING PINNIPED HAULOUT SITES
APPENDIX D	PROPOSED RIGHT-OF-WAY CONFIGURATIONS ASSOCIATED WITH THE BRADWOOD LANDING PROJECT
APPENDIX E	SOIL MAP UNITS CROSSED BY MILEPOST
APPENDIX F	RIGHT-OF-WAY WIDTHS BY MILEPOST ALONG THE PROPOSED BRADWOOD LANDING PIPELINE ROUTE
APPENDIX G	U.S. COAST GUARD LETTER OF INTENT AND WATERWAY SUITABILITY REPORT LETTER FOR THE BRADWOOD LANDING PROJECT
APPENDIX H	REFERENCES
APPENDIX I	LIST OF PREPARERS
APPENDIX J	RESPONSE OF THE FEDERAL ENERGY REGULATORY COMMISSION TO THE SAFETY ADVISORY REPORT OF THE OREGON DEPARTMENT OF ENERGY FOR THE BRADWOOD LANDING PROJECT
APPENDIX K	COMMENTS ON THE DRAFT EIS AND RESPONSES
APPENDIX L	SUBJECT INDEX

TABLES

<u>Number</u>	<u>Title</u>	<u>Page</u>
1.3-1	Major Permits, Approvals, and Consultations for the Bradwood Landing Project	1-20
1.4-1	Public and Interagency Meetings for the Bradwood Landing Project Attended by the FERC Staff	1-30
1.4-2	Environmental Issues Identified During the Pre-filing Public Scoping Process for the Bradwood Landing Project.....	1-32
1.4-3	Parties Intervening on the Bradwood Landing Project.....	1-34
1.4-4	Topics of Comments on the Draft EIS	1-35
2.1.3-1	Pile Location, Number, Length, Diameter and Water Depth Summary	2-19
2.1.4-1	Pipeline Facilities Associated with the Bradwood Landing Project.....	2-26
2.1.4-2	Aboveground Facilities Associated with the Pipeline for the Bradwood Landing Project	2-27
2.3-1	Summary of Land Requirements Associated with Construction and Operation of the Bradwood Landing Project.....	2-33
2.8.1-1	Federal Siting and Design Requirements for LNG Facilities	2-62
3.1.1-1	Comparison of Air Emissions from Burning Fossil Fuels.....	3-10
3.1.2-1	Comparison of Proposed Project to Pipeline Projects as System Alternatives.....	3-16
3.1.3-1	Comparison of Proposed LNG Import Terminals in Oregon	3-26
3.1.4-1	Data Collected by the National Data Buoy Center—Buoy 6029	3-41
3.1.4-2	Assessment and Comparison of Offshore Technology to the Proposed Project	3-47
3.1.6-1	Estimated Air Emissions Associated with Vaporizer Combustion.....	3-58
3.1.8-1	Comparison of the Proposed Bradwood Landing Pipeline to the Alternative Routes.....	3-66
3.1.8-2	Minor Route Variations Evaluated for the Proposed Pipeline Route by NorthernStar	3-67
3.1.9-1	Dredged Material Placement Alternatives.....	3-70
4.1.1-1	Generalized Stratigraphy in the Proposed Bradwood Landing Project Area	4-4
4.1.4-1	Geologic Units Crossed by Proposed Pipeline	4-24
4.1.4-2	Mines Located within 1,500 feet of the Proposed Bradwood Landing Pipeline	4-25
4.1.4-3	Potential Landslide Areas Crossed by the Proposed Bradwood Landing Pipeline in Washington.....	4-27
4.2.2-1	Estimated and Actual Compositing of DMMUs Sampled for the Bradwood Landing Project.....	4-38
4.2.2-2	Summary of Results for Heavy Metals in Sediments	4-40
4.2.2-3	Summary of Results for Dioxins and Furans in Sediments	4-41
4.2.2-4	Summary of Results for Guaiacols, Retene, and Resin Acids in Sediments	4-42
4.2.2-5	Summary of Results for Phytosterols in Sediments.....	4-43
4.2.3-1	Soil Series Crossed by the Proposed Pipeline Route.....	4-48
4.2.3-2	Acreages and Characteristics of Soils Affected by Construction of the Bradwood Landing Pipeline	4-49
4.2.3-3	Potential Contaminated Sites within 1,500 feet of the Bradwood Landing Pipeline.....	4-53
4.3.1-1	Potential Water Intakes and Discharges Associated with the Bradwood Landing Project.....	4-58
4.3.1-2	Private Water Wells Potentially within 150 feet of the Bradwood Landing Pipeline Construction Workspace.....	4-62
4.3.2-1	Summary of Section 303(d)-Listed Waterbodies Crossed by the Bradwood Landing Project in Washington	4-69
4.3.2-2	Designated Shorelines Crossed by the Bradwood Landing Project in Washington	4-69
4.3.2-3	Stormwater Runoff Discharge Locations from Clifton Road.....	4-73
4.3.2-4	LNG Carrier Intakes and Discharges while Berthed at the LNG Terminal Wharf.....	4-85
4.3.2-5	Constituent Data for Vaporizer Condensate	4-88
4.3.2-6	Waterbodies Crossed by the Bradwood Landing Project.....	4-90

TABLES (cont'd)

<u>Number</u>	<u>Title</u>	<u>Page</u>
4.4.1-1	Common Wetland Species Identified in Delineations Within the Bradwood Landing LNG Terminal Site	4-104
4.4.1-2	Wetlands Affected by the Bradwood Landing LNG Terminal.....	4-106
4.4.1-3	Wetlands Within the 400-foot-wide Study Area Associated with the Power Line	4-107
4.4.1-4	Common Wetland Species Identified in Delineations Within the Bradwood Landing Pipeline Area	4-110
4.4.1-5	Wetlands Affected by Construction and Operation of the Proposed Bradwood Landing Pipeline	4-111
4.4.1-6	Summary of Wetlands Affected by Construction and Operation of the Proposed Bradwood Landing Pipeline	4-114
4.4.1-7	NorthernStar's Request to Locate Additional Temporary Workspaces Within 50 feet of a Wetland.....	4-119
4.4.2-1	Acres of Upland Vegetative Communities Affected by the Bradwood Landing Project	4-123
4.5.1-1	Potential Impacts on EFH Due to LNG Marine Traffic	4-143
4.5.1-2	Wildlife Species Occurring within the Vegetative Communities along the Waterway and in the Vicinity of the Bradwood Landing LNG Terminal	4-145
4.5.2-1	Potential Impacts on EFH Due to the Bradwood Landing LNG Terminal.....	4-173
4.5.2-2	Acreages of Wildlife Habitats Impacted by the Bradwood Landing LNG Terminal	4-173
4.5.3-1	Fishbearing Waterbodies Impacted by the Bradwood Landing Pipeline.....	4-190
4.5.3-2	Potential Impacts on EFH Due to the Bradwood Landing Pipeline	4-190
4.5.3-3	Acreages of Wildlife Habitats Impacted by the Bradwood Landing Pipeline Facilities	4-191
4.5.3-4	Wildlife Species Occurring within the Vegetative Communities in the Bradwood Landing Pipeline Area	4-192
4.6.1-1	Federally Listed Species Potentially Occurring in the Vicinity of the Bradwood Landing Project.....	4-198
4.6.1-2	Population Estimates for the Columbian White-tailed Deer along the Lower Columbia River.....	4-213
4.6.2-1	Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project.....	4-231
4.6.2-2	Numbers of Pinnipeds Observed at Bonneville Dam by Year	4-271
4.6.3-1	Federally Listed Endangered, Threatened, or Candidate Species Potentially Occurring in the Vicinity of the Bradwood Landing Project.....	4-301
4.7.1-1	Marinas and Boat Launches in the Lower Columbia River.....	4-312
4.7.2-1	Land Uses Affected by the Construction and Operation of the Proposed LNG Terminal	4-315
4.7.3-1	Land Uses Affected by the Construction and Operation Rights-of-way for the Proposed Pipeline and Laterals	4-337
4.7.3-2	Additional Temporary Workspaces Required for Construction of the Bradwood Landing Pipeline.....	4-339
4.7.3-3	Access Roads Required for Construction of the Bradwood Landing Project.....	4-341
4.7.3-4	Land Uses Affected by Construction and Operation of Aboveground Facilities	4-342
4.7.3-5	Acres of Land Affected by Construction and Operation of the Pipeline Facilities for the Bradwood Landing Project.....	4-343
4.7.3-6	Clatsop County Comprehensive Plan Land Use Zones Related to the Bradwood Landing Pipeline.....	4-344
4.7.3-7	Structures Located Within 50 Feet of the Pipeline Construction Work Areas	4-348
4.7.3-8	Special Interest Areas in the Vicinity of or Crossed by the Bradwood Landing Pipeline Route.....	4-353

TABLES (cont'd)

<u>Number</u>	<u>Title</u>	<u>Page</u>
4.8.1-1	Existing Population in the Counties and Communities Along the Waterway for LNG Marine Traffic	4-359
4.8.1-2	Housing Characteristics in the Counties and Communities Along the Waterway for LNG Marine Traffic	4-360
4.8.1-3	Existing Economic Conditions in the Counties and Communities Along the Waterway for LNG Marine Traffic	4-361
4.8.1-4	Existing Public Services in the Vicinity of the Bradwood Landing Project.....	4-363
4.8.1-5	Density and Type of the Shipping Marine Traffic on the Columbia River	4-365
4.8.1-6	Demographics of Communities Along the Waterway for LNG Marine Vessel Traffic.....	4-373
4.8.1-7	Income Distribution of Communities Along the Waterway for LNG Marine Traffic.....	4-374
4.8.2-1	Existing Population in the Areas Where Socioeconomic Effects Would Occur as a Result of Construction and Operation of the Bradwood Landing LNG Terminal and Natural Gas Sendout Pipeline	4-375
4.8.2-2	Housing Characteristics in the Areas Where Socioeconomic Effects Would Occur as a Result of Construction and Operation of the Bradwood Landing LNG Terminal and Natural Gas Sendout Pipeline	4-376
4.8.2-3	Existing Economic Conditions in the Areas Where Socioeconomic Effects Would Occur as a Result of Construction and Operation of the Bradwood Landing LNG Terminal and Natural Gas Sendout Pipeline.....	4-377
4.8.2-4	Estimated Construction Workforce for the LNG Terminal	4-378
4.8.2-5	Sources of Construction Workers for the LNG Terminal.....	4-378
4.8.2-6	Economic Impacts of Construction of the LNG Terminal	4-379
4.8.2-7	Annual Economic Impacts of Operation of the LNG Terminal	4-380
4.8.2-8	Direct Travel Impacts in the Vicinity of the Bradwood Landing Project.....	4-388
4.8.2-9	Demographics in the Vicinity of the Bradwood Landing LNG Terminal	4-389
4.8.2-10	Income Distribution in the Vicinity of the Bradwood Landing LNG Terminal	4-390
4.8.3-1	Estimated Construction Workforce for the Pipeline Facilities	4-391
4.8.3-2	Sources of Construction Workers for the Pipeline Facilities.....	4-391
4.8.3-3	Economic Impacts of Construction of the Pipeline Facilities.....	4-392
4.8.3-4	Roads Crossed by the Bradwood Landing Pipeline Route	4-396
4.8.3-5	Demographics of Communities Crossed by Bradwood Landing Pipeline Route.....	4-398
4.8.3-6	Income Distribution of Communities Crossed by Bradwood Landing Pipeline Route.....	4-398
4.9.3-1	Native American Consultations for the Bradwood Landing Project	4-407
4.10.1-1	National Ambient Air Quality Standards	4-413
4.10.1-2	Oregon SO ₂ Ambient Air Quality Standards	4-413
4.10.1-3	Washington TSP and SO ₂ Ambient Air Quality Standards	4-414
4.10.1-4	Estimated Air Emissions from the LNG Carriers, Tugs, and Security Vessels (PM ₁₀ , SO ₂ , NO _x , and CO).....	4-415
4.10.1-5	Estimated Air Emissions from the LNG Carriers, Tugs, and Security Vessels (VOCs, CO ₂ , and CH ₄)	4-415
4.10.1-6	Stationary Source Information.....	4-417
4.10.1-7	Operating Air Emissions Summary for Proposed LNG Terminal (NO _x , CO, SO ₂ , and PM ₁₀ /PM _{2.5}).....	4-418
4.10.1-8	Operating Air Emissions Summary for Proposed LNG Terminal (VOCs, Pb, CO ₂ , and CH ₄)	4-418
4.10.1-9	Significant Emission Rates and Terminal Potential to Emit.....	4-423
4.10.1-10	AAQS Dispersion Modeling Results Summary (Terminal)	4-424

TABLES (cont'd)

<u>Number</u>	<u>Title</u>	<u>Page</u>
4.10.1-11	AAQS Dispersion Modeling Results Summary (Terminal and LNG Carrier).....	4-425
4.10.1-12	Class I Area Dispersion Modeling Results Summary (Terminal)	4-425
4.10.1-13	Estimated Total and Peak Hourly Construction Emissions for LNG Terminal (NO _x , CO, SO ₂ , and PM ₁₀).....	4-429
4.10.1-14	Estimated Total and Peak Hourly Construction Emissions for LNG Terminal (PM _{2.5} , VOCs, CO ₂ , and CH ₄)	4-429
4.10.1-15	Estimated Total and Peak Hourly Construction Emissions for Pipeline (NO _x , CO, SO ₂ , and PM ₁₀)	4-433
4.10.1-16	Estimated Total and Peak Hourly Construction Emissions for Pipeline (PM _{2.5} , VOCs, CO ₂ , and CH ₄)	4-433
4.10.2-1	Nearest Noise-Sensitive Areas	4-437
4.10.2-2	Background Noise Levels at Property Line and Nearest NSAs	4-439
4.10.2-3	Estimated Construction Equipment Noise.....	4-439
4.10.2-4	Operational Equipment List.....	4-441
4.10.2-5	Predicted L _{dn} Noise Levels at Nearest NSAs.....	4-441
4.10.2-6	Existing Sound Levels for HDD Sites	4-443
4.10.2-7	Existing Sound Levels for Valve Sites	4-443
4.10.2-8	Estimated Sound Levels for HDD Sites	4-445
4.10.2-9	Estimated Sound Levels for Valve Sites	4-446
4.11.4-1	Impoundment Areas	4-465
4.11.4-2	Thermal Exclusion Zones.....	4-468
4.11.5-1	Minimum Striking Speed to Penetrate LNG Cargo Tanks.....	4-474
4.11.5-2	LNG Spills on Water (using ABSG Methodology).....	4-478
4.11.9-1	High Consequence Areas Crossed by and Adjacent to the Bradwood Landing Pipeline.....	4-494
4.11.9-2	Natural Gas Service Incidents by Cause.....	4-496
4.11.9-3	Outside Forces Incidents by Cause (1970-1984).....	4-496
4.11.9-4	External Corrosion by Level of Control (1970-1984)	4-497
4.11.9-5	Annual Average Fatalities - Natural Gas Transmission and Gathering Systems	4-498
4.11.9-6	Nationwide Accidental Deaths	4-499
4.12-1	Existing or Proposed Activities Cumulatively Affecting Resources of Concern for the Bradwood Landing Project.....	4-501
4.12.7-1	Estimated Operational LNG Project Emissions in Clatsop County, Oregon.....	4-515

ACRONYMS AND ABBREVIATIONS

°F	degrees Fahrenheit
µg/g	micrograms per gram
µg/m ³	micrograms per cubic meter
µPa	microPascal
2006 IBE	2006 International Building Code
ABSG	ABSG Consulting, Inc.
ACDP	Air Contaminant Discharge Permit
ACHP	Advisory Council on Historic Preservation
ACRR	Astoria and Columbia River Railroad, now called the Portland Western Railroad
AERMIC	American Meteorological Society / Environmental Protection Agency Regulatory Model Improvement Committee
AERMOD	American Meteorological Society / Environmental Protection Agency Regulatory Model Improvement Committee modeling program
AMEC	AMEC Earth and Environmental, Inc.
ANSI	American National Standards Institute
APE	area of potential effect
API	American Petroleum Institute
AQCR	Air Quality Control Region
AQIA	Air Quality Impact Analysis
ASTM	American Society for Testing and Materials
BA	biological assessment
BACT	Best Available Control Technology
Bcfd	billion cubic feet per day
BEA	Bureau of Economic Analysis
bgs	below the ground surface
Bhp	brake horsepower
BIA	Bureau of Indian Affairs
BLM	Bureau of Land Management
BMP	Best Management Practice
BO	Biological Opinion
BOG	boil-off gas
BPA	Bonneville Power Administration
Btu	British thermal unit
Btu/ft ² -hr	British thermal units per square foot per hour
CAA	Clean Air Act
CAAA	Clean Air Act Amendments
Calpine	Calpine Corporation
CCC	Cowlitz County Code
CCS	carbon capture and storage
CEC	California Energy Commission
CEII	critical energy infrastructure information
CEQ	Council on Environmental Quality
Certificate	Certificate of Public Convenience and Necessity
CFR	Code of Federal Regulations
cfs	cubic feet per second
Chevron	Chevron Corporation
CLC	California State Lands Commission
CMMP	<i>Contaminated Materials Management Plan</i>
CMMS	computerized maintenance management system

ACRONYMS AND ABBREVIATIONS (cont'd)

CO	carbon monoxide
CO ₂	carbon dioxide
Coast Guard	U.S. Department of Homeland Security, Coast Guard
COC	Certificate of Compliance
COE	U.S. Army Corps of Engineers
COI	Certificate of Inspection
Commission	Federal Energy Regulatory Commission
Compensatory Mitigation Plan	Preliminary Engineering Design Draft Mitigation Plan
COTP	Captain of the Port
Council	Oregon Energy Facility Siting Council
CPSAR	Cherry Point State Aquatic Reserve
CRBG	Columbia River Basalt Group
CRD	Columbia River Datum
CREST	Columbia River Estuary Study Taskforce
CRITFC	Columbia River Intertribal Fisheries Commission
CRM	Columbia River Mile
CSCSL	Confirmed and Suspected Contaminated Sites List
CSZ	Cascadian Subduction Zone
CWA	Clean Water Act
CZMA	Coastal Zone Management Act of 1972
dB	decibels
dBA	A-weighted scale
DDT	dichloro-diphenyl-trichloroethane
DE	Design Earthquake
DEGADIS	Dense Gas Dispersion Model
Discovery Plan	Plan and Procedures for the Unanticipated Discovery of Cultural Resources and Human Remains
DMD	Dredged Material Disposal
DMEF	Dredged Material Evaluation Framework
DMMU	Dredge Material Management Units
DPS	distinct population segment
DOD	U.S. Department of Defense
DOE	U.S. Department of Energy
DOGAMI	Oregon Department of Geology and Mineral Industries
DOT	U.S. Department of Transportation
Dthd	decatherms per day
DWPA	Drinking Water Protection Area
ECSI	Environmental Cleanup Site Information System
EDNA	environmental designations for noise abatement
EFH	essential fish habitat
EIA	Energy Information Administration
EIS	Environmental Impact Statement
El Paso	El Paso Corporation
EPA	Environmental Protection Agency
EPAct	Energy Policy Act of 2005
ERP	Emergency Response Plan
ESA	Endangered Species Act of 1973
ESD	emergency shutdown

ACRONYMS AND ABBREVIATIONS (cont'd)

ESEE	Energy, social, economic, and environmental
Esperanza	Esperanza Energy LLC
ESUs	evolutionarily significant units
Excelerate	Excelerate Energy
FEMA	Federal Emergency Management Agency
FERC	Federal Energy Regulatory Commission
FHO	Flood Hazard Overlay District
FMSC	Federal Maritime Security Coordinator
FS	U.S. Department of Agriculture, Forest Service
FSO	Facility Security Officer
FSRU	floating, storage, and regasification unit
ft/s	feet per second
FWS	U.S. Fish and Wildlife Service
g	gravity
GAO	U.S. General Accounting Office
GBS	gravity-based structure
GHG	greenhouse gas
GHO	Geologic Hazards Overlay District
gpm	gallons per minute
GSI	Groundwater Solutions, Inc.
GSX	Georgia Strait Crossing
GTN	Gas Transmission Northwest Corporation
GW	gigawatt
GWMA	Groundwater Management Area
GWP	global warming potential
HAP	hazardous air pollutant
HCA	high consequence area
HDD	horizontal directional drill
HEL	highly erodible land
HMP	Habitat Mitigation Policy
HRA	Historical Research Associates, Inc.
HUD	U.S. Department of Housing and Urban Development
Hz	hertz
I	Importance Factor
I _p	Importance Factor
ICF	ICF International
IMO	International Maritime Organization
IMPLAN	Impact Analysis for Planning
INGAA	Interstate Natural Gas Association of America
JBHNR	Julia Butler Hansen National Wildlife Refuge
Jordan Cove	Jordan Cove Energy Project, L.P.
KB pipeline	Kelso Beaver Pipeline
Kitimat LNG	Kitimat LNG Inc.
KO	knockout
kPa	kilopascal
kV	kilovolt
kW	kilowatt
kWh	kilowatt-hour
L _{eq}	daytime and nighttime equivalent sound level

ACRONYMS AND ABBREVIATIONS (cont'd)

$L_{eq(24)}$	the level of steady sound with the same total (equivalent) energy as the time-varying sound of interest, averaged over a 24-hour period
L_{dn}	day-night noise level
LCFRB	Lower Columbia Fish Recovery Board
LCNHT	Lewis and Clark National Historic Trail
LDC	local distribution company
LFL	lower flammability limit
LiDAR	Light Detection and Ranging
Lighting Plan	Lighting Plan for the Bradwood Landing LNG Terminal
LNG	liquefied natural gas
LOI	Letter of Intent
LOR	Letter of Recommendation
LPG	liquid petroleum gas
LWD	Large woody debris
LWDUO	Land and Water Development and Use Ordinance
M	maximum moment magnitudes
m^2	square meter
m^3	cubic meter
m^3/hr	cubic meters per hour
MACT	Maximum Achievable Control Technology
MARAD	U.S. Department of Transportation, Maritime Administration
MARSEC	Maritime Security
MCE	Maximum Considered Earthquake
Mcf	thousand cubic feet
MDth	thousand dekatherms
mgd	million gallons per day
mg/g	milligrams per gram
mg/kg	milligrams per kilogram
mg/L	milligrams per liter
Memorandum	Memorandum of Understanding on Natural Gas Transportation Facilities
MHW	mean high water
MHHW	mean higher high water
Mitigation Plan	Mitigation Plan for the Bradwood Landing Project
MLLW	mean lower low water
MLRA	Major Land Resource Area
MLV	mainline block valve
MMBtu	million British thermal units
MMBtu/hr	million British thermal units per hour
MMcfd	million cubic feet per day
MMPA	Marine Mammal Protection Act
MMscf	million standard cubic feet
MP	milepost
MPRSA	Marine Protection, Research, and Sanctuaries Act
MRL	Method Reporting Limit
MSA	Magnuson-Stevens Fishery Conservation and Management Act
msl	mean sea level
MW	megawatt
mya	million years ago
NAAQS	National Ambient Air Quality Standards

ACRONYMS AND ABBREVIATIONS (cont'd)

NAICS	North American Industry Classification System
NAVD	North American Vertical Datum
NEPA	National Environmental Policy Act of 1969
NESHAP	National Emission Standards for Hazardous Air Pollutants
NFPA	National Fire Protection Association
NFPA 59A	National Fire Protection Association, <i>Standards for the Production, Storage, and Handling of LNG</i>
NFWF	National Fish and Wildlife Foundation
NGA	Natural Gas Act
NHPA	National Historic Preservation Act
NMFS	U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service
NO ₂	nitrogen dioxide
NO _x	nitrogen oxides
N ₂ O	nitrous oxide
NOA	Notice of Availability
NOI	<i>Notice of Intent to Prepare an Environmental Impact Statement for the Proposed Bradwood Landing LNG Project, Request for Comments on Environmental Issues, and Notice of Joint Public Meeting, and Site Visit</i>
NorthernStar	Bradwood Landing LLC and NorthernStar Energy LLC
Northwest Natural	Northwest Natural Gas Company
NPDES	National Pollutant Discharge Elimination System
NPL	National Priorities List
NRCS	USDA Natural Resources Conservation Services
NRHP	National Register of Historic Places
NSA	noise-sensitive area
NSPS	New Source Performance Standards
NTU	Nephelometric Turbidity Units
NVIC 05-05	Navigation and Vessel Inspection Circular – Guidance on Assessing the Suitability of a Waterway for Liquefied Natural Gas (LNG) Marine Traffic
NWGA	Northwest Gas Association
NWI	National Wetlands Inventory
NWS	National Weather Service
OAAQS	Oregon Ambient Air Quality Standards
OAR	Oregon Administrative Rule
OBE	Operating Basis Earthquake
OCMP	Oregon Coastal Management Program
OCRM	Office of Coast and Resource Management
ODA	Oregon Department of Agriculture
ODE	Oregon Department of Energy
ODEQ	Oregon Department of Environmental Quality
ODFW	Oregon Department of Fish and Wildlife
ODHS	Oregon Department of Human Services
ODLCD	Oregon Department of Land Conservation and Development
ODSL	Oregon Department of State Lands
ODOT	Oregon Department of Transportation
ODWR	Oregon Department of Water Resources
OEP	Office of Energy Projects
OHWM	ordinary high water mark

ACRONYMS AND ABBREVIATIONS (cont'd)

OPS	Office of Pipeline Safety
ORNHIC	Oregon Natural Heritage Information Center
ORS	Oregon Revised Statute
ORV	open rack vaporizer
ORW	Outstanding Resource Water

EXECUTIVE SUMMARY

This final environmental impact statement (EIS) for the Bradwood Landing Project, proposed by Bradwood Landing LLC and NorthernStar Energy LLC (collectively referred to as NorthernStar), has been prepared by the staff of the Federal Energy Regulatory Commission (FERC or Commission) to fulfill the requirements of the National Environmental Policy Act of 1969 (NEPA) and the Commission's implementing regulations under Title 18 Code of Federal Regulations Part 380. The purpose of this document is to inform the public and the permitting agencies about the potential adverse and beneficial environmental impacts of the proposed project and its alternatives, and to recommend mitigation measures that would avoid or reduce any significant adverse impacts.

The FERC is the federal agency responsible for authorizing onshore liquefied natural gas (LNG) import and interstate natural gas transmission facilities under the Natural Gas Act, and is the lead federal agency for the preparation of this EIS in compliance with the requirements of the NEPA. The U.S. Department of Homeland Security, Coast Guard (Coast Guard) and the U.S. Army Corps of Engineers (COE) are cooperating agencies for the development of this EIS. The Coast Guard has authority over the safety and security of LNG carriers, and the waterway for LNG marine traffic. The Coast Guard determines the suitability of the waterway for LNG marine traffic by issuing a Letter of Recommendation (LOR). The COE has authority to issue dredging and wetland permits for the project under section 10 of the Rivers and Harbors Act and section 404 of the Clean Water Act (CWA).

The Pipeline and Hazardous Materials Safety Administration of the U.S. Department of Transportation (DOT), is participating as a cooperating agency in accordance with an interagency agreement between the DOT, the FERC, and the Coast Guard. The DOT has authority to enforce safety regulations and standards for the LNG terminal beginning at the last valve before the storage tanks and the design and operation of the natural gas sendout pipeline.

PROPOSED ACTION

The purpose of the Bradwood Landing Project is to import and store LNG to provide a new source of natural gas to the Pacific Northwest. LNG is natural gas cooled to about -260 degrees Fahrenheit (F) to reduce its volume so that it can be transported long distances across oceans in specially designed ships from its point of origin to foreign markets. NorthernStar proposes to provide up to 1.3 billion cubic feet per day of natural gas to the region through interconnects at two industrial facilities, an intrastate pipeline, and an interstate pipeline system.

The waterway for LNG marine traffic would extend from the boundary of the U.S. territorial sea, located 12 nautical miles off the Pacific Coast, up the Columbia River approximately 38 miles to the LNG terminal. The proposed LNG terminal is located at the former townsite of Bradwood, in Clatsop County, Oregon, and would occupy about 40 acres of land within a 411-acre site controlled by NorthernStar. About 46 acres within a 58-acre area in the Columbia River would be dredged to create a ship maneuvering area for the terminal berth. The LNG terminal facilities would include:

- a single ship berth capable of receiving and unloading LNG carriers with cargo capacities ranging from 100,000 to 200,000 cubic meters (m³);
- two 160,000 m³ insulated LNG storage tanks;
- vapor handling system, and vaporization equipment capable of regasifying the LNG for delivery into the natural gas sendout pipeline; and
- piping, ancillary buildings, safety systems, and other support facilities.

The natural gas pipeline facilities would include:

- a 36.3-mile-long, underground, high-pressure steel sendout pipeline consisting of approximately 18.9 miles of 36-inch-diameter pipeline in Clatsop and Columbia Counties, Oregon and 17.4 miles of 30-inch-diameter pipeline in Columbia County, Oregon and Cowlitz County, Washington; and
- associated pipeline support facilities, including five meter and regulation stations, four interconnects, two pig¹ launchers, and two pig receivers.

The sendout pipeline would extend from the LNG terminal to an interconnect with the existing Williams Northwest Pipeline Corporation (Williams Northwest) interstate pipeline system north of Kelso, Washington. Between the LNG terminal and the terminus at the Williams Northwest system, the sendout pipeline would interconnect with Northwest Natural Gas Company's intrastate pipeline system, Georgia Pacific's Wauna paper mill, and Portland General Electric Company's Beaver Power Plant.

In addition to the LNG terminal and natural gas pipeline facilities, the Bradwood Landing Project would require construction of facilities that do not fall under the Commission's jurisdiction. These include electric transmission facilities, three natural gas pipeline laterals, and NorthernStar's Salmon Enhancement Initiative.

PROJECT IMPACTS AND MITIGATION

The major issues identified in our² analysis are geologic hazards, dredging-related impacts, fish entrainment, forest clearing, impacts on residents and river users, and safety. These are discussed below. The final EIS includes 110 recommended measures to mitigate or avoid environmental impacts.

Geology and Soils

The proposed Bradwood Landing LNG terminal is located in an area of a high seismic risk and is susceptible to soil liquefaction during a major earthquake. The critical safety-related components of the facility would be designed to withstand an earthquake of approximately magnitude 9 originating beneath the site on the Cascadian Subduction Zone mega-thrust fault. Measures currently proposed to mitigate soil liquefaction impacts include supporting the LNG tanks and other integral structures on deep foundations and vibroflotation to compact existing soils and new fill. The final engineering design for the LNG terminal would incorporate detailed seismic specifications and other measures to mitigate the impacts of seismic hazards and would be subject to final review and approval by the FERC's Director of the Office of Energy Projects prior to construction. We are also recommending that prior to construction NorthernStar retain the services of an independent Board of Consultants to provide oversight of the design and construction of all civil and structural components of the project with particular emphasis on the seismic design requirements and geological hazard mitigation measures for both the LNG terminal and sendout pipeline.

Landslide areas along the pipeline route would be mitigated by one or more of the following: relocation of the pipeline route; horizontal directional drill crossing of the feature to place the pipeline below potential failure surfaces; and instrumentation of the pipe and/or the surrounding rock or soil to monitor strain in the pipe and movement of the surrounding ground. NorthernStar would conduct additional studies and produce a Final Pipeline Design Geotechnical Report with site-specific mitigation

¹ A pig is an internal tool used to clean and dry a pipeline and/or to inspect it for damage or corrosion.

² The pronouns "our," "we," and "us" refer to the environmental staff of the FERC's Office of Energy Projects.

measures prior to construction which would be subject to review by the Board of Consultants and approval by the Director of OEP.

About 700,000 cubic yards of sediment would be dredged from the Columbia River bottom to create the proposed ship maneuvering area adjacent to the navigation channel. NorthernStar tested samples of sediments from the dredge area. Although some contaminants were detected in the samples, the concentrations were relatively low, and none exceeded screening levels or threshold effects levels used to identify concentrations of concern. The sediments are primarily sand and would settle quickly. As a result, the size of the sediment plume would be small and confined to an area immediately surrounding the dredging site. Modeling conducted by NorthernStar indicates that dredging for the maneuvering area would cause a reduction in stream flow through Clifton Channel and minor changes to the main navigation channel of the Columbia River. NorthernStar prepared a *Shoreline Monitoring Plan* for the LNG terminal to address shoreline erosion that may occur as a result of dredging for the maneuvering basin. NorthernStar proposes to place up to the entire 700,000 cubic yards of dredged material at the terminal site. Any sediments not placed at the terminal site would be deposited at the existing Wahkiakum County Sand Pit site on the northwestern end of Puget Island via a temporary pipeline.

Water and Wetlands

Water would be appropriated from the Columbia River during construction for ground improvement, hydrostatic testing, and general purposes. During operation, river water would be withdrawn for weekly testing of the fire suppression system. Permanent and temporary surface water intakes that withdraw water from the Columbia River would be screened in accordance with the U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service (NMFS) and Oregon Department of Fish and Wildlife (ODFW) requirements to minimize impacts on aquatic resources. In addition, ballast and engine cooling water would be taken on during LNG carrier offloading operations. NorthernStar would construct and install a system capable of delivering filtered river water to the LNG carriers. This system would use a screened water intake located at the ship berth that would minimize the entrainment and impingement of juvenile fish. Since the issuance of the draft EIS, NorthernStar has stated that some LNG carriers may arrive at the terminal without the necessary retrofitting in place to allow the use of the screened water supply system. NorthernStar would continue to offer incentive-based contractual agreements for vessels to accommodate the screened water supply system. We are recommending that NorthernStar require that LNG carriers are retrofitted or develop an alternative system for non-retrofitted carriers that would offer similar protection.

LNG carriers that have not been retrofitted to use the proposed screened water supply system could routinely discharge cooling water at the wharf. We are recommending that NorthernStar develop performance standards that address water quality impacts from cooling water discharges at the LNG terminal. Operation of the submerged combustion vaporizers (SCV) at the LNG terminal would generate up to 160 gallons per minute of condensate water. The condensate water would be neutralized and discharged to the Columbia River using an outfall/diffuser system designed to rapidly mix the 68 °F condensate with the river water.

Ninety-four waterbodies would be crossed by the pipeline. The HDD or conventional bore method would be used at up to 23 of the waterbody crossings to avoid or minimize impacts on aquatic resources. Construction of the LNG terminal facilities would result in impacts on about 15 acres of wetlands and, of these, about 13 acres would be permanently lost. Construction of the pipeline facilities would affect about 98 acres of wetlands, while operation of the pipeline would result in the permanent conversion of approximately 15 acres of forested wetlands to other wetland types within the permanent right-of-way. Impacts on wetlands and water resources would be minimized through measures specified

in *Erosion and Sediment Control Plan for Oregon – Bradwood Landing Pipeline* (ESC), *Construction Stormwater Pollution Prevention Plan for Washington – Bradwood Landing Pipeline* (SWPPP), and *Wetland and Waterbody Construction and Mitigation Procedures Plan*; and the FERC’s *Upland Erosion Control, Revegetation, and Maintenance Plan* (Plan) and *Wetland and Waterbody Construction and Mitigation Procedures* (Procedures). NorthernStar would also mitigate construction-related impacts by complying with CWA section 404 and section 401 permit conditions. In addition, NorthernStar has proposed a *Preliminary Engineering Design Draft Mitigation Plan* (Compensatory Mitigation Plan), including restoration and/or preservation programs at Hunt Creek, Svensen Island, and Delameter Creek, to create or enhance wetland habitats as compensation for wetlands and habitats impacted by its project.

Vegetation and Wildlife

Construction of the LNG terminal, and its associated power line, would affect about 31 acres of forest and 13 acres of shrub-scrub vegetation in upland areas. The 37 acres of the terminal site affected by construction that are not permanently converted to industrial use would be replanted with native species. About 180 acres of forest and 7 acres of shrub-scrub vegetation would be affected by construction of the pipeline. Non-forested portions of the pipeline right-of-way would be restored and seeded after construction. Upland forest would be replanted with in-kind trees, except for a 30-foot-wide strip over the pipeline centerline. Routine maintenance of a 10-foot-wide corridor centered on the pipeline would keep that area in an herbaceous state. To minimize impacts from the potential spread of noxious weeds from the disturbed right-of-way, NorthernStar developed a *Noxious Weed and Soil-borne Plant Disease Control Plan*.

We have identified Essential Fish Habitat (EFH) that may be affected by the project for more than 90 species of groundfish, 5 coastal pelagic species, 2 species of salmon, and 13 highly migratory aquatic species. Our EFH assessment was combined with our Biological Assessment (BA) and submitted to the NMFS and U.S. Department of the Interior, Fish and Wildlife Service (FWS). We identified federally listed endangered or threatened species that potentially occur in the vicinity of the Bradwood Landing Project, including: 13 anadromous salmonids and the North American green sturgeon; four reptiles (sea turtles); nine mammals (including seven whales, Steller sea lion, and Columbian white-tailed deer); six birds; one invertebrate; and three plants. In response to our BA and EFH Assessment, the NMFS and FWS requested additional information; therefore, the FERC staff is currently revising that document. The revised analysis will be provided to the NMFS and FWS, and consultation under the Magnuson-Stevenson Act and Endangered Species Act will be concluded before any construction of facilities is allowed to proceed.

Land Use, Residences, and Recreation

Communities overlapped by the Zones of Concern along the waterway for LNG marine traffic include Warrenton and Astoria in Oregon, and Skamokawa and Cathlamet in Washington. The Zones of Concern along the waterway would also overlap state and local parks and public recreation or special use areas such as marinas. In addition, the Lewis and Clark National Wildlife Refuge and the Julia Butler Hansen National Wildlife Refuge are located along the waterway. LNG marine traffic may have visual impacts for people residing in the shoreline communities, traveling along highways adjacent to the waterway, using the parks and public interest areas, or using the river. Visual impacts would be short term, as it would typically take an LNG carrier only a few minutes to pass through a viewshed while traveling at average speeds between 8 and 12 knots.

The closest residences to the LNG terminal are about 0.5 mile away on Puget Island in Wahkiakum County, Washington. Construction impacts on these residences could include inconvenience caused by terminal lighting. We are recommending that NorthernStar submit a final lighting plan to

mitigate those operational impacts. The LNG storage tanks at the terminal may have minor visual impacts for river users and residents of Puget Island, Cathlamet, and Skamokawa, Washington. Visual impacts from the LNG terminal would generally be minor, because views are modified by topography, vegetation, and distance. Three homes have been identified within 50 feet of the construction right-of-way for the pipeline. We are recommending that NorthernStar file site-specific residential mitigation plans prior to construction. The project would not be located in areas that have a disproportionately high percentage of minorities, Native Americans, or low income populations.

The Bradwood Landing Project is subject to a federal Coastal Zone Consistency Review because it would involve activities within the coastal zone of Oregon and require several federal permits and approvals. We are recommending that prior to construction, NorthernStar should be required to demonstrate that its project is consistent with Oregon's Coastal Management Program.

Socioeconomics

The project would have a beneficial impact on the local economy. Total construction costs are estimated to be over \$700 million, with a total outlay for wages and benefits of about \$110 million. Operation of the LNG terminal would generate 65 jobs, with a total annual payroll of about \$3.9 million. In addition, NorthernStar would spend about \$1.4 million per year for tug boat rentals, and the tug boats would employ about 40 people. During operation of the LNG terminal, NorthernStar would pay about \$7.8 million per year in property taxes to Clatsop County, Oregon. Taxes would also be paid to Columbia County, Oregon, and Cowlitz County, Washington during operation of the pipeline.

There may be impacts on public services in the unlikely situation of an accident involving an LNG carrier or at the terminal. In addition to NorthernStar's proposed safety and security measures, the Coast Guard would enforce additional measures to ensure the safety of the waterway and LNG terminal. However, some local communities have expressed concerns that their current staffing and equipment for law enforcement, fire fighting, and rescue are not adequate to respond to a project-related accident. NorthernStar has developed a draft Emergency Response Plan (ERP), which includes a Cost-Sharing Plan to assist local first responders to acquire necessary resources. We will review the draft ERP in consultation with the appropriate agencies and NorthernStar would file a revised ERP before construction could begin.

Cultural Resources

NorthernStar provided cultural resources survey reports to the Oregon and Washington State Historic Preservation Offices (SHPO). Those reports identified the Lewis and Clark National Historic Trail and the Astoria and Columbia River Railroad as properties within the area of potential effect that may be eligible for the National Register of Historic Places (NRHP). However, we and the SHPOs agree that the project would have no adverse effect on those properties.

We contacted Native American tribes that may have historically occupied or used the project area and might attach religious or cultural significance to historic properties in the area of potential effect. No traditional cultural properties, religious, cultural, or sacred sites that may be affected by the project were identified by any tribe, NorthernStar's cultural resources consultant, or by the SHPOs.

We have not yet completed the process of complying with section 106 of the National Historic Preservation Act for this project. Cultural resources surveys are still needed for about 11 miles of the proposed pipeline route and associated ancillary facilities where access has not yet been obtained. Furthermore, both SHPOs have requested additional data. Once survey data are complete, the FERC, in consultation with the cooperating agencies and the SHPOs, would make determinations of NRHP

eligibility and project effects. If any historic properties would be affected by the proposed project, we would seek ways to resolve adverse effects. We are recommending that NorthernStar defer construction until: 1) cultural resource surveys are completed and evaluation reports, any required treatment or avoidance plans, and a cultural resources management plan are filed with the Secretary; 2) the SHPOs' comments on reports and plans are filed with the Commission; and 3) the Advisory Council on Historic Preservation has been given an opportunity to comment if any historic properties would be adversely affected.

Air Quality and Noise

Operation of the proposed LNG terminal would result in air emissions from stationary equipment (SCVs and emergency engines), LNG carriers, and tugs. NorthernStar would minimize air emissions from the LNG terminal through the use of clean fuel, best management practices for operation and maintenance procedures, and limiting annual hours of operation from the diesel-fired units. Based upon the air quality modeling, operational emissions from the LNG terminal would not have a significant effect on regional air quality. In addition, the emissions from construction of the LNG terminal and associated pipeline would not be regionally significant. Operation of the pipeline would result in little emissions and would not be significant.

Noise would be generated during construction of the pipeline and during construction and operation of the LNG terminal. In most areas, the increase in noise during construction would be localized, temporary, and limited primarily to daylight hours. However, noise associated with dredging operations could occur up to 24 hours per day, 7 days per week for a period of approximately 2 months. NorthernStar would incorporate noise attenuation measures during construction and operation to minimize impacts on nearby noise-sensitive areas and meet the FERC and local requirements. We are recommending that NorthernStar provide plans to mitigate noise from construction and operation of the facilities.

Safety and Reliability

We evaluated the safety of both the proposed facilities and the related LNG carrier transit through the Columbia River navigation channel. As part of our evaluation, we performed a cryogenic design and technical review of the proposed terminal design and safety systems. Several areas of concern were noted with respect to the proposed facility, and we identified specific recommendations to be addressed by NorthernStar prior to initial site preparation, prior to construction after final design, prior to commissioning, or prior to commencement of service.

Thermal radiation distances were calculated for 1,600 to 10,000 British thermal units per square foot per hour (Btu/ft²-hr) incident flux levels for an LNG storage tank impoundment fire. The resulting distances would be 377 feet for the 10,000 Btu/ft²-hr zone; 714 feet for the 3,000 Btu/ft²-hr zone; and 912 feet for the 1,600 Btu/ft²-hr zone. Although the flammable vapor dispersion exclusion zones would extend off-site into the navigation channel, there are no prohibited land uses within the channel. Therefore, the vapor exclusion zone requirements of 49 CFR 193.2059 would be met. Flammable vapor hazard distances were calculated for accident scenarios in the process area which resulted in a distance of 243 feet to the 2.5 percent average gas concentration.

Thermal radiation and flammable vapor hazard distances were calculated for an accident or an attack on a 140,000-m³ LNG carrier. For 1.0-, 1.4-, 2.5-, 3.0-, and 3.9-meter-diameter holes in an LNG cargo tank, we estimated distances to range from 2,154 to 5,225 feet for a thermal radiation level of 1,600 Btu/ft²-hr, the level, which is hazardous to unprotected persons located outdoors. Based on a 1.0-meter-diameter hole, an unignited release would result in an estimated pool radius of 421 feet. The unignited

vapor cloud would extend to 10,237 feet to the lower flammable limit (LFL) and 13,618 feet to one-half the LFL. The results of these calculations are in agreement with the Zones of Concern used by the Coast Guard in assessing the waterway suitability. However, the evaluation of safety is more than an exercise in calculating the consequences of worst case scenarios. Rather, it is a determination of the acceptability of risk which considers: the probability of events, the effect of mitigation, and the consequences of events. Based on the extensive operational experience of LNG shipping, the structural design of an LNG carrier, and the operational controls imposed by the Coast Guard and the local pilots, the likelihood of a cargo containment failure and subsequent LNG spill from a vessel casualty – collision, grounding, or allision – is highly unlikely. As a result, the risk to the public from accidental spills from LNG carriers should be considered negligible.

Unlike accidental causes, historical experience provides little guidance in estimating the probability of a terrorist attack on an LNG carrier. For an LNG import terminal proposal that would involve having a large volume of energy transported and stored, the perceived threat of a terrorist attack is a primary concern of the local population and requires that resources be directed to mitigate possible attack paths. While the risks associated with the transportation of any hazardous cargo can never be entirely eliminated, they can be managed.

If an accidental or intentional breach of an LNG carrier resulting in a release of LNG were to occur during transit along the waterway, impacts on the various environmental resources within the Zones of Concern could result. LNG would not contaminate water, because it is not soluble, it floats, and the LNG would vaporize shortly after being spilled. The primary hazard from an LNG spill would be a pool fire if the vapors are ignited. A pool fire could have adverse affects on vegetation, wildlife, structures, and people. In general, the area of effect of an LNG release and any resulting fire would be fairly limited in area and short-lived. The severity and duration of the impacts would vary depending on the resource and its distance from the source, as resources in Zone 1 would be more severely impacted than resources in Zone 3. However, with implementation of the mitigation measures described in the Coast Guard's Waterway Suitability Report (WSR), a release would be highly unlikely and the potential impact on resources would be less than significant.

Based on its review of NorthernStar's Waterway Suitability Assessment (WSA), the Coast Guard advised the FERC in its WSR dated February 28, 2007 that to make the Columbia River suitable for the LNG marine traffic associated with the Bradwood Landing Project, specific risk mitigation measures would be necessary. These measures would include a 500-yard moving safety and security zone around LNG carriers in transit, a 200-yard fixed security zone around the LNG carriers moored at the proposed LNG terminal, and one-way traffic in designated portions of the waterway.

ALTERNATIVES CONSIDERED

Alternatives considered by the FERC include no action or postponed action, system alternatives, LNG terminal site alternatives, LNG terminal layout alternatives, and pipeline route alternatives. While denying project approval or taking no action (or postponing action) would eliminate the environmental impacts identified in this EIS, the project objective would not be met of providing a new source of natural gas for the Pacific Northwest.

We did not identify any existing interstate pipeline systems that could provide additional supplies of natural gas to the Pacific Northwest equivalent to the volumes proposed for the Bradwood Landing Project without major expansions. Converting one of the five Pacific Northwest LNG "peak shaving" storage facilities into an import terminal would not be feasible. An offshore LNG terminal near the mouth of the Columbia River would not be a viable alternative to the Bradwood Landing Project. This is due to rough sea conditions off the Oregon Coast, technological limitations related to offshore LNG

import terminal designs; and the additional environmental impacts associated with a longer sendout pipeline. We considered five newly proposed jurisdictional interstate pipelines as system alternatives to the Bradwood Landing Project but did not find any of them to be environmentally preferable. A number of proposed onshore LNG import terminals along the West Coast in North America were examined as potential alternatives. However, we concluded that none of these facilities would meet all the objectives of the Bradwood Landing Project. We considered alternative LNG terminal locations along the coast of Washington and Oregon and along the Columbia River, but that none appear to have clear environmental advantages over the Bradwood Landing location. The FERC would review individual projects based on their own merits and allow the market to decide which projects ultimately are built.

We have reviewed the various alternatives related to LNG terminal facility design and power line route designs, and found that NorthernStar's current proposal is reasonable given technical, engineering, economic, and environmental considerations. Furthermore, we did not identify dredge material placement alternatives that were preferable to the proposed action

We evaluated four major sendout pipeline routes as alternatives to the route proposed by NorthernStar, but none would provide significant environmental advantages over the proposed pipeline route. NorthernStar adopted some minor route variations that we found environmentally preferable to its original route, but other route variations did not need to be adopted because they had no clear environmental advantages. However, additional route modifications would likely be necessary following completion of the Final Pipeline Design Geotechnical Report to minimize slope stability problems along the pipeline.

The proposed action for the Coast Guard is to issue an LOR finding the waterway suitable for LNG marine traffic with conditions. Among the conditions that may be included are: 1) establishment of a 500-yard moving safety/security zone during LNG vessels' transit of the waterway, including the requirements for one-way LNG marine traffic along certain portions of the waterway such as at turns and for a 200-yard security zone around the LNG vessel when it is moored at the LNG terminal; 2) a 50-yard security zone around the LNG terminal when there is not a vessel at the dock; 3) the submission by the applicant of an annual review of its WSA to evaluate if any conditions in the waterway have changed that would require issuance of a new LOR and submit the annual review to the Captain of the Port (COTP) for his/her review and issuance of a new LOR if necessary; 4) the requirement that LNG vessels must board a pilot(s) at least 5 miles before the Columbia River Buoy and for at least the first 6 months, at least two pilots must be on board throughout the transit and that at least two tugs escort the vessel along the waterway with a third to assist with turning and mooring; 5) implementation of a Coast Guard-approved *LNG Vessel Transit Management Plan*; 6) improvements to the Columbia River's Vessel Traffic Information System; and 7) availability of Coast Guard as well as other safety and security resources to implement the above security measures. If these and other conditions to the LOR are imposed, the potential for accidental releases or releases from terrorist attacks would be minimized.

Reasonable alternatives to the Coast Guard's proposed action with conditions include: 1) issuance of a Coast Guard LOR finding the waterways suitable for LNG marine traffic without conditions; and 2) issuance of a Coast Guard LOR finding the waterways not suitable for LNG marine traffic (no action alternative). The Coast Guard's preferred alternative is to issue an LOR finding the waterway suitable for LNG traffic with certain conditions.

The no action alternative for the Coast Guard would avoid any project-related environmental effects in the waterway; however, it would also prevent LNG carriers from delivering LNG to the proposed import terminal and the project objectives would not be met. A reasonable alternative to the Coast Guard action of issuing an LOR, which finds the waterway suitable for LNG marine traffic with certain conditions, is to issue an LOR without any conditions. With this alternative, some of the adverse

economic effects of the conditions would be lessened. However, the potential for adverse environmental effects would be greater if conditions were not imposed.

In summary, we have determined that NorthernStar's proposed project, as modified by our recommended mitigation measures, is the preferred alternative that can meet the project objectives.

PUBLIC INVOLVEMENT AND AREAS OF CONCERN

As part of the Commission's Pre-filing Process, on September 23, 2005, the FERC issued a *Notice of Intent to Prepare an Environmental Impact Statement for the Proposed Bradwood Landing LNG Project, Request for Comments on Environmental Issues, and Notice of Joint Public Meeting, and Site Visit*. This notice was sent to elected federal, state, and local government officials; agency representatives; environmental and public interest organizations; Native American tribes; and local libraries and newspapers. The notice encouraged project stakeholders or interested parties to provide input on environmental issues that should be addressed during the environmental review process. The Coast Guard published a notice in the Federal Register on September 9, 2005 for preparing an LOR as to the suitability of the Columbia River navigation channel for LNG marine traffic.

On September 29, 2005, the Coast Guard and FERC staff conducted a joint public scoping meeting in Knappa, Oregon, to provide an opportunity for the general public to learn more about the proposed project. The FERC held a second public meeting in Cathlamet, Washington on October 26, 2005 to answer questions regarding the Commission's Pre-filing and the NEPA review processes. Through the scoping process, we received comments on a variety of environmental issues. Those issues are addressed in this EIS.

The FERC issued a Notice of Availability (NOA) of the draft EIS on August 17, 2007. The NOA established a 120-day period for comments on the draft EIS, ending on December 24, 2007 (later extended to December 26, 2007). In addition, a total of six public comment meetings were held November 5 through November 8 in Clatskanie and Knappa, Oregon and in Longview and Cathlamet, Washington. Comments from the public meetings, as well as written comments on the draft EIS, are provided along with our responses in Appendix K.

MAJOR CONCLUSIONS

We conclude that construction and operation of the Bradwood Landing Project would have limited adverse environmental impacts. However, that implementation of NorthernStar's proposed mitigation measures, and additional measures we recommend, would substantially reduce the environmental impact of the project. The primary reasons for our decision are:

- the final engineering design for the LNG terminal would incorporate detailed seismic specifications and other measures to mitigate the impacts of seismic hazards, and mitigation measures would be implemented along the pipeline route to address landslides and other geological hazards;
- NorthernStar would implement its project-specific ESC Plans, a SWPPP, and *Wetland and Waterbody Construction and Mitigation Procedures Plan*, and follow the FERC staff's Plan and Procedures to mitigate impacts on soils, wetlands, and water resources;
- NorthernStar would implement various mitigation plans to compensate for impacts on waterbodies, wetlands, vegetation, and habitats;

- consultations with the COE, Coast Guard, NMFS, FWS, Oregon Department of Land Conservation and Development, Oregon Department of Environmental Quality, Oregon Department of State Lands, ODFW, Washington Department of Ecology, Washington Department of Fish and Wildlife, Oregon and Washington SHPOs, and other appropriate agencies would be completed before NorthernStar would be allowed to begin construction;
- the proposed LNG terminal would meet the federal safety regulations regarding the thermal radiation and flammable vapor dispersion exclusion zones, and appropriate safety features would be incorporated into the design and operation of the LNG import terminal and LNG carriers; and
- an environmental inspection and mitigation monitoring program would be implemented to ensure compliance with all mitigation measures that become conditions of any FERC authorization.

In addition, our decision is based on the Coast Guard's preliminary determination in the WSR that the waterway may be suitable for LNG marine traffic if additional measures and operational controls are implemented, including:

- availability of Coast Guard as well as other safety and security resources, including additional safety measures when a cruise ship is in port, security boardings, waterway monitoring, shoreline patrols, and vessel escorts to implement the additional security measures;
- establishment of a safety/security zone around the LNG vessel and the dock;
- a restriction on the size of LNG carriers to a capacity of 148,000 m³ until a completed site-specific risk analysis for larger ships is approved by the COTP;
- operational and pilotage requirements, including tug escorts and multiple pilots;
- upgrades to navigational aids including installation of three aids at Bradwood, a Physical Oceanographic Real-Time System station at Bradwood contracted with the National Oceanographic and Atmospheric Administration to provide real-time river level, current, and weather data, and a Doppler docking station;
- augmentation of shoreside firefighting capabilities to provide protection services to the facility as well as communities along the transit route;
- implementation of a public notification system to notify the public along the transit route;
- implementation of a Regional Communication Plan and associated equipment to ensure that the facility, associated command centers, emergency responders, Coast Guard, tug operators, escort vessels, and pilots are able to communicate effectively; and
- improvements to the Columbia River's Vessel Traffic Information System, including: augmentation of a camera monitoring system capable of monitoring the entire route and detecting vessel traffic in wind, rain, fog, and dark conditions; and installation of an Automatic Identification System repeater located in Astoria.

1.0 INTRODUCTION

On June 5, 2006, Bradwood Landing LLC and NorthernStar Energy LLC (affiliates of NorthernStar Natural Gas, Inc.) filed applications with the Federal Energy Regulatory Commission (FERC or Commission) under sections 3(a) and 7(c) of the Natural Gas Act (NGA). The applications were noticed in the Federal Register on June 15, 2006. In Docket No. CP06-365-000, Bradwood Landing LLC seeks authorization to site, construct, and operate a liquefied natural gas (LNG) import terminal at Bradwood, about 38 miles up the Columbia River from its mouth, in Clatsop County, Oregon. In Docket No. CP06-366-000, NorthernStar Energy LLC seeks a Certificate of Public Convenience and Necessity (Certificate) to construct and operate a new natural gas pipeline and ancillary facilities to connect the proposed LNG terminal to the existing Williams Northwest Pipeline Corporation (Williams Northwest) interstate natural gas pipeline system in Cowlitz County, Washington. In Docket Nos. CP06-376-000 and CP06-377-000, NorthernStar Energy LLC also applied for a blanket certificate under Part 157, Subpart F of the Commission's regulations and requested issuance of a blanket certificate under Subpart G of Part 284, respectively. Hereafter, Bradwood Landing LLC and NorthernStar Energy LLC are referred to collectively as NorthernStar. The project, including the LNG terminal and pipeline components, is referred to as the Bradwood Landing Project.

The FERC is the federal agency responsible for authorizing applications to construct and operate onshore LNG import and interstate natural gas transmission facilities. For the Bradwood Landing Project, the FERC is the lead federal agency for the preparation of this environmental impact statement (EIS) in compliance with the requirements of the National Environmental Policy Act of 1969 (NEPA), the Council on Environmental Quality (CEQ) regulations for implementing the NEPA (Title 40, Code of Federal Regulations (CFR) 1500-1508), and the FERC's regulations implementing the NEPA (18 CFR Part 380).

The U.S. Army Corps of Engineers (COE) and the U.S. Department of Homeland Security, Coast Guard (Coast Guard) are cooperating agencies for the development of this EIS. A cooperating agency has jurisdiction by law or special expertise with respect to environmental impacts involved with the proposal, and is involved in the NEPA analysis. The Pipeline and Hazardous Materials Safety Administration (PHMSA) within the U.S. Department of Transportation (DOT) is participating in the NEPA analysis under the terms of an interagency agreement between the PHMSA, the FERC, and the Coast Guard, issued February 11, 2004.¹

The Coast Guard has authority over the safety and security of LNG carriers, the marine traffic route, and the LNG terminal. The Coast Guard determines the suitability of the waterway for LNG marine traffic by issuing a Letter of Recommendation (LOR) (see section 1.3.1). The COE has authority to issue dredging and wetland permits for the project (see section 1.3.2). The DOT has authority to enforce safety regulations and standards for the LNG terminal beginning at the last valve immediately before the storage tanks and the design and operation of the sendout pipeline.

<p>The vertical line in the margin identifies text that has been modified in the final EIS and differs from the corresponding text in the draft EIS.</p>
--

This final EIS discloses and assesses the potential environment impacts that may be associated with the construction and operation of the Bradwood Landing Project in Clatsop and Columbia

¹ The *Interagency Agreement Among the Federal Energy Regulatory Commission, United States Coast Guard, and Research and Special Programs Administration for the Safety and Security Review of Waterfront Import/Export Liquefied Natural Gas Facilities* is available for viewing by the public through the FERC Internet web page at www.ferc.gov, then clicking on Industries, LNG, Safety and Inspections.

Counties, Oregon, and Cowlitz County, Washington. NorthernStar's proposed facilities would transport up to 1.3 billion cubic feet per day (Bcfd) of imported natural gas to markets in the Pacific Northwest.

The LNG import terminal proposed by Bradwood Landing LLC would include:

- a dredged maneuvering area off of the Columbia River navigation channel;
- a berth capable of receiving LNG carriers with cargo capacities ranging from 100,000 to 200,000 cubic meters (m³);
- a set of four 16-inch-diameter LNG unloading arms, including two liquid unloading arms, one hybrid arm, and a vapor return arm on the wharf, and a 1,240-foot-long, 32-inch-diameter cryogenic LNG transfer pipeline and 6-inch-diameter LNG recirculation pipeline extending from the berth to the LNG storage tanks;
- two insulated LNG storage tanks, each with a useable volume of over 1 million barrels, or 160,000 m³;
- a vapor management system to handle the boil-off gas (BOG) that occurs during the unloading process, including vapor return blowers and knockout (KO) drum on the wharf, vapor handling pipework, two BOG compressors, and a BOG condenser;
- an LNG sendout system, consisting of six submerged in-tank LNG discharge pumps (three in each storage tank) and five sendout pumps;
- seven submerged combustion vaporizers (SCV), of which six would normally operate and one would be a back-up, to re-gasify the LNG and provide natural gas through a metering station to the inlet valve of the sendout pipeline;
- support buildings, including a warehouse/administrative building, control building, switch rooms, compressor building, and gatehouse/security building;
- utilities, including a 1.5-mile-long, 115-kilovolt (kV) power line and switchyard, and an 800-kilowatt (kW) emergency diesel-fueled generator;
- screened water intakes, pumps, and piping to supply water to unloading ships for cooling and ballast, and for other site uses; and
- a fire protection and detection system, including a firewater pumphouse, and
- a security system including fencing.

The natural gas pipeline facilities proposed by NorthernStar Energy LLC would include:

- a 36.3-mile-long, underground, high-pressure welded steel sendout pipeline consisting of approximately 18.9 miles of 36-inch-diameter pipeline in Clatsop and Columbia Counties, Oregon and 17.4 miles of 30-inch-diameter pipeline in Columbia County, Oregon and Cowlitz County, Washington;
- five meter stations, including at the LNG terminal, the Georgia-Pacific Wauna paper mill (Wauna Mill) delivery point, the interconnection with the Northwest Natural Gas

Company (Northwest Natural) interstate pipeline system, the Portland General Electric Company (PGE) Beaver Power Plant delivery point, and the interconnection with Williams Northwest pipeline system; and

- at least five mainline block valves (MLV), two pig² launchers, and two pig receivers.

Some commentors on our³ draft EIS questioned whether the Williams Northwest system has the capacity to transport the additional volumes of natural gas to be provided through the importation of LNG by the Bradwood Landing Project. In a February 9, 2006 data request to NorthernStar, we asked for a description of any expansions that may be necessary on either the Northwest Natural or Williams Northwest systems in order to accommodate the new volumes of natural gas proposed to be delivered through the Bradwood Landing pipeline. In a response dated March 28, 2006, NorthernStar stated that: “No expansions of the Northwest Natural pipeline system or the Williams-Northwest Pipeline system would be necessary in order to accommodate the new volumes of natural gas to be delivered by the Bradwood Landing LNG Project.”

In its motion to intervene in this proceeding, filed July 6, 2006, Williams Northwest stated that: “Although NorthernStar currently does not have an interconnect agreement with Northwest, Northwest is willing to accommodate an interconnect with the proposed Bradwood Landing Pipeline as long as the conditions outlined in the Commission’s interconnect policy...are satisfied.” While Williams Northwest acknowledges the value of enhanced gas supply diversity in the region, it pointed out that its existing pipeline capacity (both north and south flow) from the proposed interconnect point with NorthernStar is currently fully contracted on a long-term basis for transportation services from existing primary receipt points. Without an expansion of its system, Williams Northwest believes that the proposed interconnect with NorthernStar would only serve as an alternative receipt point for Williams Northwest’s existing shippers.

However, it is our opinion that just because a pipeline is fully subscribed does not mean that pipeline capacity is never available for new entrants. The Williams Northwest system could handle the additional new volumes provided by the Bradwood Landing Project without expansion, under several different sets of circumstances. Although the Bradwood Landing Project is designed for a maximum sendout capacity of 1.3 Bcfd, it should be noted that for the last few years existing LNG import terminals along the Eastern and Gulf coasts of the United States have been operating at about 50 percent capacity. Further, a significant amount of the volumes being imported are in the summer months when spare pipeline capacity is widely available. Even in the winter months, and the shoulder seasons, capacity can be made available on fully subscribed pipelines through various Commission programs such as reverse open seasons, capacity turnbacks, capacity releases, and interruptible capacity. By encouraging the use of these programs, the Commission ensures that, to the greatest extent possible, contracted pipelines are fully utilized. In addition, the FERC has recently proposed new rules which would further aid in efficient use of available capacity by allowing asset managers to tie capacity released on a pipeline with gas supplies.

The Bradwood Landing Project would require construction of some facilities that do not fall under the Commission’s jurisdiction. These include electric transmission facilities and three natural gas pipeline laterals. The waterway to the LNG terminal for the LNG carriers is an additional component of the project for the purpose of this EIS. The Bradwood Landing Project also would include development of several mitigation sites as well as a Salmon Enhancement Initiative (SEI).

² A pig is an internal tool used to clean and dry a pipeline and/or to inspect it for damage or corrosion.

³ The pronouns “we,” “us,” and “our” refer to the environmental staff of the FERC’s Office of Energy Projects. The FERC issued the draft EIS for the Bradwood Landing Project on August 17, 2007.

1.1 PURPOSE AND NEED

The purpose of the Bradwood Landing Project is to provide a new source of natural gas to the Pacific Northwest through importation of LNG. LNG is natural gas that has been cooled to about -260 degrees Fahrenheit (°F) for shipment and storage as a liquid. As a liquid, LNG is about 600 times more compact than its equivalent amount of natural gas vapors. LNG is typically produced in foreign countries with excess supplies of natural gas, and transported long distances across oceans using specially designed ships. The 15 LNG exporting nations hold about 33 percent of the world's natural gas reserves (U.S. Department of Energy, Energy Information Administration (EIA); 2008a).

NorthernStar has not revealed its expected sources for the LNG, but most likely it would come from LNG exporting countries around the Pacific Basin, including Australia, Malaysia, Indonesia, and perhaps even the United States (Alaska has a liquefaction and LNG export facility). In 2006, Trinidad and Tobago was the largest supplier of LNG for the existing import terminals operating on the East and Gulf coasts, accounting for about 67 percent of all LNG imported into the United States (EIA, 2008a). At the Bradwood Landing import terminal, the LNG would be stored and then vaporized back into natural gas for transportation by pipeline into the existing national grid.

NorthernStar's project is specifically designed to provide up to 1.3 Bcfd of natural gas to the Pacific Northwest by:

- delivering natural gas to the Wauna Mill at Wauna, Oregon and the PGE Beaver Power Plant at Port Westward, Oregon;
- interconnecting with Northwest Natural's existing bidirectional intrastate pipeline facilities capable of transporting gas to their Mist underground storage facility; and
- interconnecting with Williams Northwest interstate pipeline system.

By creating access to new and competitively-priced LNG supplies, the proposed project would diversify available sources of energy and increase the supply of natural gas to meet estimated future demand in the region, which would contribute to natural gas price stabilization. The states of Washington and Oregon do not produce much natural gas.⁴ Natural gas is currently supplied to the region through the existing interstate pipeline systems operated by Williams Northwest and Gas Transmission Northwest Corporation (GTN). Williams Northwest is a subsidiary of the Williams Companies, Inc. (Williams), while GTN is part of the TransCanada Corporation (TransCanada). These systems bring to the Pacific Northwest natural gas produced in the provinces of British Columbia and Alberta, Canada, and the Rocky Mountain states of Wyoming, Colorado, and New Mexico. In total, these existing pipelines have a transportation capacity of 4.1 Bcfd as they enter the region (from Canada and Idaho), with 2.2 Bcfd in capacity targeted for the California market. In 2007, total natural gas consumption in Washington and Oregon was estimated to average about 1.2 Bcfd (ICF International (ICF), 2007).

In 2006, natural gas represented 22 percent of the total primary energy used in the United States. More than half of all American homes are heated with natural gas, and it is the fuel of choice for about 41 percent of the nation's industrial sector (James A. Baker III Institute for Public Policy (Baker Institute), 2008). In the Pacific Northwest, natural gas accounts for about 50 percent of the energy currently consumed. It is used for residential space and water heat, for commercial and industrial processes, and for electric generation. Industrial users account for about 28 percent of the natural gas

⁴ Oregon produced 621 MMcf of natural gas in 2006, or about 0.27 percent of its consumption (ODE, 2008b).

consumed in the region. However, industrial use of natural gas in the Pacific Northwest declined between 1995 and 2007. Residential use represents a little more than 24 percent of the natural gas market in the Pacific Northwest, but has grown about 23 percent between 1995 and 2007. The number of natural gas customers increased nearly 13 percent between 2000 and 2005, despite a regional economic slump and higher commodity prices. About 30 percent of the total gas market in the Pacific Northwest is for electric generation. This sector has shown the greatest growth since the early 1990s, as newly-built gas-fired electric generation plants increased total power outputs by 5.5 gigawatts (GW) or a factor of five (NWGA, 2007; ICF, 2007).

In the Pacific Northwest, use of natural gas should continue to grow in the future due to additional gas-fired electric generation, and population increases that will provide more residential customers. Currently, more than 20 percent of the region's electric generation is fueled by natural gas. About 60 percent of the total power generation capacity in the Pacific Northwest has been added since 2001 (NWGA, 2007). Between 2001 and 2003, about 3,350 megawatts (MW) of new power generation was added to the Northwest; most of it fueled by natural gas, including 1,675 MW in Oregon (ODE, 2005a). Over the last 3 years (2006-2008) about 1,438 MW in additional gas-fired electric generation was scheduled to come online in the Pacific Northwest (Northwest Power and Conservation Council, 2008). Nationally, about 52 percent of all new power plants built since 1995 have been gas fired, and natural gas accounts for 90 percent of all new MW of capacity installed over the last 12 years in the United States (Baker Institute, 2008). Natural gas is the cleanest burning fossil fuel, and demand from the electric generation industry should increase in the future as the government seeks to find ways to reduce air pollution and greenhouse gases, including carbon emissions, to address climate change issues.

Modeling conducted by the Baker Institute (2008) projected that natural gas demand in the United States will grow by about 1.3 percent per year for the next two decades. The NWGA (2007) estimated that natural gas consumption in the Pacific Northwest should increase at an average of 1.9 percent per year over the next 5 years, for a total rise of 7.2 percent through 2012, under normal weather conditions and expected economic and population growth. Under its base case, residential natural gas consumption is expected to increase about 9 percent in total by 2012, while natural gas use for power generation would increase about 12 percent over that period. According to a 2007 study produced by ICF for the Washington Energy Facility Siting Council, future natural gas use in the Pacific Northwest should grow at an annual rate in excess of 3 percent per year, with total consumption in Washington and Oregon combined reaching 741 Bcf per year by 2025. ICF expects residential demand for natural gas in Washington and Oregon to increase by a total of about 58 percent between 2007 and 2025, while gas used for electric generation would increase by about 180 percent in that same period.

The NWGA believes that existing natural gas interstate pipeline and local storage facilities may be adequate to meet demand in the Pacific Northwest through about 2012. However, weather dependent demand, including natural gas needed for residential heating in the winter and electric generation for air conditioning in the summer, may result in short-term spikes that cannot be met by current capacity. Weather-driven peak demand will grow faster than baseline (non-weather dependent) demand in the future. If the Bradwood Landing Project were authorized by the end of 2008, it may be ready to be placed into service by the end of 2011. Therefore, this project could help to ameliorate the predicted future gap between natural gas supply and regional demand, and assist in providing additional volumes during periods of peak demand when current interstate natural gas capacity may fall short.

Demand for natural gas in North America is expected to grow nearly 20 percent by 2030. The EIA predicts, in its 2008 Annual Energy Outlook, that natural gas use in the United States will increase from about 21.9 trillion cubic feet (Tcf) in 2006 to 24.3 Tcf by 2016 (EIA, 2007d). This is lower than previous EIA projections because of higher natural gas prices and slower growth in demand for natural

gas for electric generation. In its 2007 Outlook, the EIA predicted that natural gas consumption in the United States would reach 26.1 Tcf by 2030 (EIA, 2007a).

Since the early 1980s, natural gas production in the United States has fallen short of demand. Domestic production of natural gas in the United States has risen from about 17.5 Tcf in 1991 to about 19.3 Tcf in 2006 (EIA, 2007b). Meanwhile, natural gas consumption in the United States grew to about 21.9 Tcf by 2006. The shortfall between domestic production and consumption has been bridged by importing natural gas, mainly from Canada. In the future, the Pacific Northwest will have to increasingly compete with the rest of North America for its share of natural gas supplies from Western Canadian and Rocky Mountain producers (NWGA, 2007). Providing natural gas to meet future demands in the Pacific Northwest would be constrained by North American supplies and existing pipeline infrastructure.

The Western Canada Sedimentary Basin (WCSB), extending from British Columbia to Saskatchewan, produces nearly 98 percent of the natural gas used in Canada, and represents about 23 percent of the total production in North America. About 16 percent of all natural gas consumed in the United States is imported from foreign countries, with Canada being the source of almost 86 percent of the total amount imported in 2006 (EIA, 2008a). In 2007, about 90 percent of the natural gas imported into the Pacific Northwest came from Canada.

Since 2001, production from the WCSB has been relatively constant, at about 6 Tcf per year. While, in 2006, the Pacific Northwest received about 7 percent of the total natural gas imported into the United States from Canada (about 255 Bcf), the Midwest received about 46 percent (1,632 Bcf) and the Northeast got 28 percent (1,012 Bcf) (EIA, 2008a). However, the WCSB has been characterized as a “mature” production area, and it is forecasted to decline in the future from current production levels of about 17 Bcfd to less than 15 Bcfd by 2013 (ICF, 2007; NWGA, 2007). The EIA (2008a) believes that WCSB producers are having difficulties maintaining output because of rising production costs and declining well productivity. At the same time that WCSB production would be declining, natural gas consumption in Canada should be increasing. For example, natural gas is used for heavy oil and tar sand development in Alberta and for gas-fired power plants in Ontario. Imports of natural gas from Canada to the United States are predicted to fall from 3.6 Tcf in 2006 to 1.2 Tcf in 2030 (ODE, 2008b). Therefore, imports from the WCSB into the Pacific Northwest are expected to decrease over time, at a rate of about 50 million cubic feet per year through 2015 (ICF, 2007).

According to the EIA (2007a), most of the onshore natural gas resources in the continental United States have already been discovered. Over the last 20 years, the amount of federal lands open for new gas exploration has shrunk from 75 percent to 17 percent (Baker Institute, 2008). Production from conventional onshore sources in the lower 48 states is expected to decline from about 6.4 Tcf in 2005 to about 4.9 Tcf by 2030. Natural gas from deep water offshore wells in the Gulf of Mexico, currently accounting for about 15 percent of cumulative domestic marketed production, is predicted to peak at 3.1 Tcf by 2015 and decline to 2.1 Tcf by 2030. Increases in domestic production in the future would mainly come from Alaska and unconventional onshore resources, including coalbed methane, tight sandstones, and gas shale. However, natural gas from Alaska is currently shut in; although there are plans for a future natural gas pipeline from Alaska.⁵

Natural gas production in the Rocky Mountain states has shown steady growth, from 3.6 Bcfd in 1995 to 8.1 Bcfd in 2007. It now represents about 12 percent of U.S. production. The region is estimated to have about 142 Tcf remaining. Production in the Rockies is projected to increase to almost 10 Bcfd by 2013, and up to 12.2 Bcfd by 2025 (NWGA, 2007; ICF, 2007).

⁵ The ODE (2008a) indicated that a natural gas pipeline would not be completed from Alaska until 2018 at the earliest.

Currently, the Pacific Northwest receives about 10 percent of its natural gas from the Rockies. This gas is transported through the existing Williams Northwest system, which interconnects with TransCanada's existing GTN system at several locations in Washington and Oregon. Because of constraints in existing pipeline capacity, deliveries of Rocky Mountain natural gas into the Pacific Northwest are expected to stay at current levels, at about 300 MMcfd, for the next several years (ICF, 2007).

Most of the new production from the Rockies is currently transported to markets in the Midwest and Eastern United States. For example, the Rockies Express Pipeline LLC (REX), a joint venture between Kinder Morgan Energy Partners L.P. and Sempra Pipelines and Storage, recently installed a 718-mile-long, 42-inch-diameter pipeline capable of transporting 1.5 Bcfd from Colorado to Missouri, in Docket No. CP06-354-000. REX is proposing, in Docket No. CP07-208-000, to extend its pipeline an additional 639 miles eastward to Ohio. In addition, a partnership between Alliance Pipeline and Questar Overthrust Pipeline recently announced plans for an 800-mile-long pipeline between Wamsutter, Wyoming and Emerson, Minnesota that would transport Rocky Mountain gas to markets in the Midwest (Inside FERC, 2008b; Natural Gas Intelligence, 2008c).

However, there are also recently announced plans to bring additional volumes of Rocky Mountain gas to the West Coast in the future. Both the Bronco Project, proposed by Spectra Energy, and the Ruby Project, proposed by El Paso Corporation (El Paso) would have pipelines extending from the Opal hub in southwestern Wyoming to the California border near Malin, Oregon (Inside FERC, 2007; Natural Gas Intelligence, 2008g, 2008h; Gas Daily, 2007). The so-called Sunstone Project, proposed by Williams Northwest and TransCanada, would consist of a pipeline paralleling Williams Northwest existing mainline between Opal, Wyoming and Stanfield, Oregon. In partnership with Puget Sound Energy, Williams Northwest would then use the newly proposed Blue Bridge Project pipeline to connect to Seattle, Washington (Williams, 2008; Oregonian, 2008; Natural Gas Intelligence, 2008e, 2008i; Inside FERC, 2008b). GTN, which can receive Rocky Mountain gas from Williams Northwest for delivery to the Pacific Northwest, northern Nevada, and northern California, is planning an expansion of its system in Oregon through the newly proposed Palomar Project. All of these newly proposed pipelines, which are in different stages of development and review, are discussed further in section 3.1.2.2.

A number of commentors on our draft EIS stated that they believed the natural gas from the Bradwood Landing LNG terminal would go to markets in California rather than the Pacific Northwest. NorthernStar presented a study conducted by Wood Mackenzie Limited⁶ to support its position that the main purpose of its proposed Bradwood Landing Project is to provide a new source of natural gas to the Pacific Northwest through the importation of LNG. The Wood Mackenzie Limited study indicated that at an average sendout rate of 1 Bcfd, 50.2 percent of natural gas from the Bradwood Landing LNG terminal would go to Oregon consumers, 30.3 percent would go to Washington consumers, and less than 20 percent would go to Idaho, northern California, and Nevada combined. At an average sendout of 400 MMcfd, 73 percent of natural gas from the Bradwood Landing LNG terminal would go to end users in Oregon, 26 percent would go to Washington customers, and less than 1 percent would go to other states combined.

In its comments on our draft EIS, filed December 21, 2007, the Northwest Industrial Gas Users stated: "The uncontroverted fact is that the Pacific Northwest needs access to new gas supplies and that the LNG terminal proposed by NorthernStar would help meet those needs. What is abundantly clear is that the claims by opponents of LNG that new gas supplies are not needed in the Pacific Northwest are

⁶ The Wood Mackenzie study was filed by NorthernStar in its FERC proceeding on February 21, 2008 as part of a package of materials previously provided to Clatsop County during its land use hearings about the project. These materials (accession number 20008033-9121) are available to the public through the FERC's internet web page at www.ferc.gov using the elibrary link.

patently false. The energy supply picture in the Pacific Northwest overwhelmingly shows that our region will benefit from the siting of an LNG terminal in Oregon. To suggest, as some have, that the only beneficiaries of such a terminal would be California consumers ignores all the realities facing gas consumers in Oregon, Washington, and Idaho.”

The importation of LNG as a new supplemental source of natural gas to meet future demand in the Pacific Northwest would mitigate against the predicted decline of imports from Canada, and constraints of the current interstate pipeline system to bring in additional volumes from the Rocky Mountain region. Unlike North America, where much of the resource base has already been exploited, there is ample potential for growth in LNG supply from countries with large untapped natural gas reserves. LNG represented about 14 percent of all natural gas imported into the United States in 2006 (EIA, 2008a). The Baker Institute (2008) estimated that by 2030, the United States would rely on imported LNG to account for about 31 percent of its natural gas consumption. The EIA (2007a) projected that LNG imports into the United States will increase from about 584 Bcf in 2006 to 4.5 Tcf by 2030. Even the ODE (2008a) has conceded that the United States would have to import LNG from abroad in order to make up for declining domestic natural gas production.

The Pacific Northwest historically has enjoyed natural gas prices below the national average because of its relative proximity to the WCSB and the Rockies, and local competition from hydropower plants that provide a significant amount of energy for the region. Natural gas prices have recently increased dramatically in the Pacific Northwest, and this trend will continue unless additional new sources of natural gas can be imported into the region. Between 2002 and 2005, the wellhead price of natural gas more than doubled (NWGA, 2007). Wholesale natural gas prices in Oregon increased 168 percent between 1999 and 2004, and between 1999 and 2005 residential rates rose 84 percent (ODE, 2005a, 2008a). According to the Washington Utilities and Transportation Commission (WUTC) (2006), natural gas prices in that state have soared as much as 300 percent over the last several years. Nationally, natural gas prices increased between 73 to 128 percent from 1999 to 2006 for all end-users (EIA, 2007c).

In its 2007 Annual Energy Outlook reference case, the EIA projected that wellhead prices for natural gas in the lower 48 continental United States would rise from \$5.01 per thousand cubic feet (mcf) in 2005 to \$5.89 per mcf by 2030. The Northwest Power and Conservation Council (2007) forecasts price escalation for natural gas in the region after 2010. The EIA (2008b) estimated that the spot price of natural gas at the Henry Hub will rise from \$7.17 per mcf in 2007, to \$7.93 per mcf in 2009. The California Energy Commission (CEC) (2007a) predicted that by 2017 the price of natural gas at the Malin, Oregon Hub could exceed the price at the Henry Hub. ICF (2007) had a slightly different scenario, predicting that natural gas prices at the Henry Hub would cost \$9.83 per million British thermal unit (MMBtu) in 2021, and \$9.54 per MMBtu at Malin by the same date, assuming that a pipeline was in operation from Alaska by then.

Higher natural gas prices will have negative impacts on the regional economy. The ODE (2008a) admitted that any reduction in the sources of natural gas to Oregon would disrupt the state's economy; particularly the manufacturing segment. In 2000, 1.2 percent of total personal income in Oregon was spent on purchasing natural gas (ODE, 2005a). The EIA (2007c) indicated that higher natural gas prices up to 2006 adversely affected local distribution companies (LDC) and residential customers. The number of LDC natural gas customers in arrears and the dollar value of their overdue accounts have been rising. The U.S. Federal Reserve Bank estimated that a doubling of natural gas prices would result in a reduction of gross domestic product growth between 0.6 to 2.1 percent (Baker Institute, 2008). The U.S. Department of Commerce (2005) found that higher natural gas prices between 2000 and 2004 reduced national civilian employment by an average of almost one-half million jobs per year, with about 79,000 lost jobs in manufacturing. Higher natural gas prices push up

consumer costs, reduce real disposable income, slow industrial growth, affect the competitiveness of American manufacturing, and reduce the number of new jobs created in the national economy (U.S. Department of Commerce, 2006).

According to the NWGA (2007), an LNG import terminal located in the Pacific Northwest would promote regional natural gas supply diversity and reliability, lower shipping costs, stabilize prices, and may stimulate the economy. The CEC (2007a) believes that the insertion of LNG into the West Coast mix could produce natural gas price reductions. ICF (2007) agrees that the importation of LNG in the future would put downward pressure on Pacific Northwest natural gas prices. NorthernStar commissioned Dr. Philip Romero, of the Lunquist College of Business, University of Oregon, to perform an analysis of the impact of LNG on the economy of the Pacific Northwest. In Dr. Romero's opinion, an LNG import terminal with a capacity of 1 Bcfd would increase natural gas supplies to the region by 10.3 to 51.5 percent, depending on utilization, and reduce gas prices by between 6.7 and 33.7 percent. A stable supply of natural gas in the future would benefit manufacturing and other industries, and result in higher disposable incomes for Northwest households. His "top-down" macroeconomic estimates suggested that a 10 percent reduction in natural gas prices could result in an increase in regional gross domestic product in 2012 between \$222 million and \$826 million, increase regional employment by between 5,100 to 20,300 jobs, and raise total household incomes between \$54 million and \$214 million (Romero, 2007).

A recent study by the ODE (2008b)⁷ indicated that natural gas from imported LNG may cost more than natural gas produced in North America and transported to the Pacific Northwest by interstate pipelines. Currently, Atlantic Basin LNG imported to East and Gulf Coast existing LNG terminals is generally priced 8 to 9 percent higher than North American produced natural gas. The cost of Pacific Basin LNG may even be higher than that. The ODE cited a case where a contract between Indonesia and Japan priced LNG at twice the cost of North American LNG. The same report by the ODE stated that: "natural gas use in Oregon is likely to rise over the next twenty years. New sources of natural gas will be needed to meet this demand." However, if new interstate pipelines are authorized and built, and transport domestically produced gas at substantially lower costs than imported LNG, then the market may not support the construction of LNG import terminals in Oregon.

The above discussion of project purpose and need is merely a brief summary, to satisfy the requirements of the CEQ regulations for implementing the NEPA, which state that an EIS should only "briefly specify the underlying purpose and need" for a proposed project (40 CFR 1502.13). The Commission will more fully consider the need for the Bradwood Landing Project when making its decision about the project, and will fully disclose its determinations in the project Order.

1.2 PURPOSE AND SCOPE OF THIS STATEMENT

Different federal actions are to be undertaken by the cooperating agencies producing this EIS. The FERC must decide whether or not to authorize the construction and operation of the onshore facilities proposed for the Bradwood Landing Project. The COE must decide whether or not to issue dredging and wetland permits. The Coast Guard must decide whether or not the waterway is suitable for LNG marine traffic. However, all of the cooperating agencies must consider the potential environmental impacts of NorthernStar's proposal as disclosed in this EIS prior to making their decisions.

⁷ The ODE report was conveyed to the FERC through a letter from the Governor of Oregon filed May 9, 2008. It is available for viewing by the public through the FERC's Internet webpage at www.ferc.gov, using the eLibrary feature, and looking up accession number 20080512-5063.

A draft EIS was prepared and issued for public review and comment on August 17, 2007. This document is a final EIS that has been prepared to respond to comments received on the draft EIS. All substantive changes between the draft EIS text and this final EIS are indicated by vertical bars that appear in the margins. The distribution list for the final EIS is provided in Appendix A.

Our principal purposes in preparing this EIS are to:

- identify and assess potential impacts on the natural and human environment that would result from the implementation of the proposed actions;
- describe and evaluate reasonable alternatives to the proposed actions that would avoid or minimize adverse effects on the human environment;
- identify and recommend specific mitigation measures, as necessary, to minimize the environmental impacts; and
- facilitate public involvement in identifying the significant environmental impacts.

The FERC will use the results of the EIS as an element in its review of NorthernStar's applications. After this final EIS is released, the FERC will determine whether the project should be authorized. Commission approval will only be granted if, after a consideration of both environmental and non-environmental issues, the FERC finds that the proposed project is in the public interest. The environmental impact assessment and mitigation development discussed herein will be important factors in this determination. Likewise, the Coast Guard will base its LOR on the environmental analysis contained in this EIS, in addition to consideration of waterway navigational suitability. The COE will use the results of this EIS in its review of NorthernStar's applications for permits pursuant to section 404 of the Clean Water Act (CWA) and section 10 of the Rivers and Harbors Act (RHA).

Our analysis in this EIS focuses on the facilities that are under the FERC's jurisdiction (i.e., the LNG import terminal and sendout pipeline proposed to be constructed by NorthernStar). Because it would be an integral element of the project, this EIS will also address the potential environmental impacts associated with a nonjurisdictional power line to be built to provide electric services to the LNG terminal. The waterway to the LNG terminal is included to address the Coast Guard's proposed action of issuing an LOR for the project.

The topics addressed in this EIS include geology; soils and sediments; water use and quality; wetlands; vegetation; wildlife and aquatic resources; threatened, endangered, and special-status species; land use, recreation, and visual resources; cultural resources; socioeconomics and traffic; air quality and noise; reliability and safety; and cumulative effects. The EIS describes the affected environment as it currently exists, discusses the environmental consequences of the proposed project, and compares the project's potential impact to that of alternatives. The EIS also presents our conclusions and recommended mitigation measures.

1.3 PERMITS, APPROVALS, AND REGULATORY REQUIREMENTS

The FERC, Coast Guard, and COE are required to comply with section 7 of the Endangered Species Act of 1973 (ESA), the Magnuson-Stevens Fishery Conservation and Management Act (MSA), and section 106 of the National Historic Preservation Act (NHPA). As the lead federal agency for the Bradwood Landing Project, the FERC has undertaken the lead role for consultations under these statutes for itself and the cooperating agencies. The status of compliance with those acts is described in this EIS.

At the federal level, other agency permits and approvals include compliance with the CWA, RHA, Clean Air Act (CAA), Coastal Zone Management Act (CZMA), and Coast Guard regulations relating to LNG waterfront facilities. Table 1.3-1 lists the major federal, state, and local permits, approvals, and consultations identified for construction and operation of the Bradwood Landing Project.

1.3.1 Coast Guard Review

The Coast Guard exercises regulatory authority over LNG facilities that affect the safety and security of port areas and navigable waterways under Executive Order 10173; the Magnuson Act (50 United States Code (USC) § 191; the Ports and Waterways Safety Act of 1972, as amended (33 USC § 1221 et seq); and the Maritime Transportation Security Act of 2002 (46 USC § 701). The Coast Guard is responsible for matters related to navigation safety, vessel engineering and safety standards, and all matters pertaining to the safety of the facilities or equipment located in or adjacent to navigable waters up to the last valve immediately before the receiving tanks. The Coast Guard also has authority for LNG facility security plan review, approval, and compliance verification as provided in 33 CFR 105, and siting as it pertains to the management of vessel traffic in and around the LNG facility. As required by its regulations, the Coast Guard is responsible for issuing an LOR as to the suitability of the waterway for LNG marine traffic. Issuance of the LOR would be based on the following items:

- density and character of marine traffic;
- locks, bridges, and other manmade obstructions in the waterway;
- environmental effects of LNG carriers during transit from open water to the facility;
- maritime security (MARSEC)/port security considerations; and
- the following factors adjacent to the facility:
 - depth of water;
 - tidal range;
 - protection from high seas;
 - natural hazards, including reefs, rocks, and sandbars;
 - underwater pipes and cables; and
 - distance of berthed vessels from the channel and the width of the channel.

In accordance with 33 CFR 127.007, each applicant must submit a Letter of Intent (LOI) to the local Captain of the Port (COTP) to begin the LOR process. NorthernStar submitted an LOI to the Coast Guard for the project on January 18, 2005.

On June 14, 2005, the Coast Guard issued a *Navigation and Vessel Inspection Circular – Guidance on Assessing the Suitability of a Waterway for Liquefied Natural Gas (LNG) Marine Traffic* (NVIC 05-05). The purpose of this NVIC is to provide guidance to applicants seeking to construct and operate shore-side LNG import terminals regarding the timing and scope of the Coast Guard process necessary for the consideration of safety and security issues, including LNG marine traffic. NVIC 05-05 itemizes data to be included in a Waterway Suitability Assessment (WSA) to be produced by an applicant, and outlines the roles of the COTP and Federal Maritime Security Coordinators (FMSC) in the review and validation of the WSA by the Coast Guard.

NorthernStar submitted its Preliminary WSA to the Coast Guard on December 29, 2005, and in response to Coast Guard comments, a Follow-on WSA was produced in May 2006. The Coast Guard provided the FERC with its Waterway Suitability Report (WSR) on February 28, 2007. See section 4.11.5 of this EIS for additional discussion of marine safety.

1.3.2 COE Review

The COE is the primary agency responsible for issuing dredging and wetland permits pursuant to section 404 of the CWA and section 10 of the RHA.

1.3.3 Clean Water Act and Rivers and Harbors Act

The CWA (33 USC § 1344) addresses the issue of managing developments to improve, safeguard, and restore the quality of the nation's waters, including coastal waters, and to protect the natural resources and existing uses of those waters. Under section 404 of the CWA, the COE issues permits (after notice and opportunity for public hearings) for the discharge of dredged or fill material into waters of the United States at specified disposal sites. The U.S. Environmental Protection Agency (EPA) has the authority to review and veto COE decisions on section 404 permits. Section 10 of the RHA (33 USC § 403) regulates any work or structures that potentially affect the course, condition, or capacity of a navigable waterway. It requires authorization from the COE for building any wharfs, piers, jetties, or other structures or excavating or filling in any port, navigable river, or other waters of the United States.

NorthernStar must obtain Water Quality Certifications pursuant to section 401 of the CWA and National Pollutant Discharge Elimination System (NPDES) permits pursuant to section 402 of the CWA. The federal authority to issue these certifications and permits has been delegated to the Oregon Department of Environmental Quality (ODEQ) in Oregon and the Washington State Department of Ecology (WDE) in Washington.

On March 8, 2007, NorthernStar submitted its NPDES permit application to the ODEQ. In a letter dated April 18, 2007, the ODEQ informed NorthernStar that it would not process the application until after it receives a Land Use Compatibility Statement (LUCS) from Clatsop County. To cover its proposed actions in Oregon, NorthernStar submitted a Joint Permit Application (JPA) to the COE and ODEQ in October 2006, seeking permits under sections 401 and 404 of the CWA. NorthernStar revised its JPA in March 2007. To obtain permits under sections 401 and 404 of the CWA for its actions in Washington, NorthernStar submitted, also in October 2006, a Joint Aquatic Resources Permit Application (JARPA) to the COE and the WDE. This JARPA was revised in March 2007, then withdrawn by NorthernStar, and resubmitted in October 2007. The COE issued a notice of these applications on October 18, 2007 and participated in a public meeting with the ODEQ regarding the applications on February 13, 2008 (see table 1.3-1). Section 4.3.2 of this EIS contains a more detailed discussion of potential project-related impacts on surface water, including addressing compliance with the CWA.

1.3.4 Clean Air Act

The primary objective of the CAA, as amended, is to establish federal standards for various pollutants from both stationary and mobile sources and to provide for the regulation of polluting emissions via state implementation plans. In addition, the CAA is designated to prevent significant deterioration in certain areas where air quality exceeds national standards and to provide for improved air quality in areas that do not meet federal standards (nonattainment areas).

The EPA has regulatory authority under the CAA. The EPA provides review and oversight of these regulations but has delegated permitting authority to the ODEQ in Oregon and the Southwest Clean Air Agency (SWCAA) in southwest Washington. Emissions from all phases of construction and operation of the proposed LNG terminal and pipeline would be subject to applicable federal and state air regulations. Section 4.10.1 of this EIS has a detailed discussion of air quality issues.

NorthernStar submitted an Air Contaminant Discharge Permit application for the Bradwood Landing Project to the ODEQ on March 28, 2007, and a revised application on April 9, 2007. On April 10, 2007, the ODEQ advised NorthernStar that it found the application incomplete because it did not contain a LUCS from Clatsop County under OAR 340-216-0040(1(k)).

1.3.5 Endangered Species Act

Section 7(a)(1) and (2) of the ESA, as amended, require that federal agencies use their authorities to further the conservation of listed species and that any project authorized, funded, or conducted by a federal agency should not “jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species which is determined...to be critical” (16 USC § 1536(a)(1) and (2)(1988)). The lead federal agency, or the applicant as a non-federal party, is required to consult with the U.S. Department of the Interior Fish and Wildlife Service (FWS) and the U.S. Department of Commerce National Oceanic and Atmospheric Administration, National Marine Fisheries Service (NMFS) to determine whether any federally listed or proposed endangered or threatened species or their designated critical habitat occur in the vicinity of the proposed project. If, upon review of existing data or data provided by the applicant, the federal agency determines that these species or habitats may be affected by the proposed project, it is required to prepare a biological assessment (BA) to identify the nature and extent of adverse impacts, and to recommend measures that would avoid the habitat and/or species, or would reduce potential impacts to acceptable levels.

The FERC submitted a BA for the Bradwood Landing Project to the NMFS and FWS on March 19, 2007. Because we have found that the project is likely to adversely affect some listed species, our BA requested that the FWS and NMFS develop Biological Opinions (BO) as to whether authorizing the Bradwood Landing Project may jeopardize the continued existence of any listed species. The FWS and NMFS provided comments on the BA in letters dated April 20, and May 11, 2007, respectively. The FERC staff and our third-party environmental contractor participated in a series of meetings and conference calls with representatives of the NMFS, FWS, and NorthernStar to address comments on our BA. The FERC intends to revise its BA in response to the FWS’s and NMFS’s comments, including new information provided by NorthernStar. The FERC will only allow project construction to proceed after we have completed formal consultations with the FWS and NMFS in compliance with the ESA and MSA. See section 4.6 of this EIS for details of our ESA analysis.

1.3.6 Magnuson-Stevens Fishery Conservation and Management Act

The MSA, as amended by the Sustainable Fisheries Act of 1996 (Public Law 104-267), established procedures designed to identify, conserve, and enhance Essential Fish Habitat (EFH) for those species regulated under a federal fisheries management plan. The MSA requires federal agencies to consult with the NMFS on all actions or proposed actions authorized, funded, or undertaken by the agency that may adversely affect EFH (MSA §305(b)(2)). Although absolute criteria have not been established for conducting EFH consultations, the NMFS recommends consolidated EFH consultations with interagency coordination procedures required by other statutes, such as the NEPA, the Fish and Wildlife Coordination Act, or the ESA to reduce duplication and improve efficiency (50 CFR 600.920(e)). As part of the consultation process for this project, we consolidated an EFH Assessment with the BA, prepared pursuant to the ESA, on behalf of the FERC and the federal cooperating agencies for this project. See section 4.5.1.2 of this EIS for the status of the MSA review.

1.3.7 Marine Mammal Protection Act

All marine mammals are protected under the Marine Mammal Protection Act (MMPA) of 1972. This act was amended by the United States Congress in 1994. The MMPA prohibits, with certain exceptions, the taking of marine mammals in United States waters and by United States citizens on the high seas and the importation of marine mammals and marine mammal products into the United States. The term “take,” as defined in section 3 of the MMPA, means “to harm, hunt, capture, or kill, or attempt to harass, hunt, capture or kill any marine mammal” (16 USC § 1362(13)). “Harassment” is also defined in the MMPA (at USC § 1362(18)) and in regulations promulgated by the NMFS (at 50 CFR 216.3).

Sections 101(a)(5)(A) and (D) of the MMPA direct the U.S. Secretary of Commerce, through the NMFS, to allow, upon request, the incidental, but not intentional, taking of small numbers of marine mammals of a species or population stock by U.S. citizens who engage in a specified activity (other than commercial fishing) within a specific geographic region if certain findings are made and either regulations are issued or, if the taking is limited to harassment, a notice of authorization is provided to the public for review. Authorization would be granted by the NMFS if it finds that the taking will have a negligible impact on the species or stock, will not have an unmitigatable adverse impact on the availability of the species or stock for subsistence uses (where relevant), and it prescribes permissible methods of taking, and requirements pertaining to the mitigation, monitoring, and reporting of such taking. NMFS has defined “negligible impact” as “an impact resulting from the specified activity that cannot be reasonably expected to, and is not reasonably likely to, adversely affect the species or stock through effects on annual rates of recruitment or survival.”

NorthernStar has stated that it will apply for an Incidental Harassment Authorization pursuant to MMPA section 101(a)(5)(D). The NMFS may use relevant portions of this EIS during its review, and may adopt measures to protect marine mammals outlined in this EIS. It may also require additional mitigation and monitoring measures to ensure that the taking result in the least practicable adverse impact on affected marine mammal species or stocks. The public would have an opportunity to comment to the NMFS in response to its Notice of Receipt of an application for an Incidental Harassment Authorization, or a request for the implementation of regulations governing incidental taking, and following the publication of the proposed rule.

Impacts from the Bradwood Landing Project on marine mammals are discussed in section 4.6.2. In addition, marine mammals listed under the ESA will be discussed in detail in the revised BA and EFH Assessment.

1.3.8 National Historic Preservation Act

Section 106 of the NHPA requires the lead federal agency to take into account the effects of an undertaking on historic properties, and afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment. Historic properties are cultural resources that are listed on or eligible for listing on the National Register of Historic Places (NRHP), including prehistoric or historic sites, districts, buildings, structures, objects, or properties of traditional religious or cultural importance. The ACHP promulgated regulations for the implementation of section 106 at 36 CFR 800. In accordance with those procedures, the FERC allowed NorthernStar, as a non-federal party, to assist in the preparation of information and analyses necessary for us to comply with the NHPA. Section 4.9 includes a summary of the status of investigations to comply with the NHPA.

1.3.9 Coastal Zone Management Act

In 1972, Congress passed the CZMA to “preserve, protect, develop, and where possible, to restore or enhance, the resources of the nation’s coastal zone for this and succeeding generations” and to “encourage and assist the states to exercise effectively their responsibilities in the coastal zone through the development and implementation of management programs to achieve wise use of the land and water resources of the coastal zone” (16 USC § 1452, section 303 (1) and (2)).

Section 307 (c)(3)(A) of the CZMA states that “any applicant for a required federal license or permit to conduct an activity, in or outside the coastal zone, affecting any land or water use or natural resource of the coastal zone of that state shall provide a certification that the proposed activity complies with the enforceable policies of the state’s approved program and that such activity will be conducted in a manner consistent with the program.” In order to participate in the coastal zone management program, a state is required to prepare a program management plan for approval by the U.S. Department of Commerce, National Oceanic and Atmospheric Administration, Office of Coast and Ocean Resource Management (OCRM). Once the OCRM has approved a plan and its enforceable program policies, a state program gains “federal consistency” jurisdiction. This means that any federal action (e.g., a project requiring federally issued licenses or permits) that takes place within a state’s coastal zone must be found to be consistent with state coastal policies before the federal action can take place.

The Columbia River Basin is exempt from the CZMA, except for the zone of significant tidal influence. The only part of the Bradwood Landing Project subject to federal CZMA review is the LNG import terminal at Bradwood. None of the proposed project facilities fall within the Washington coastal zone.

The Oregon Department of Land Conservation and Development (ODLCD) is the state’s designated coastal management agency and has established the Oregon Coastal Management Program (OCMP). The program’s mission is to work in partnership with coastal local governments, state and federal agencies, and other stakeholders to ensure that Oregon’s coastal and ocean resources are managed, conserved, and developed consistent with statewide planning goals. To accomplish this mission, the program combines various state statutes for managing coastal lands and waters into a single, coordinated package. These include: 1) the 19 Statewide Planning Goals, which are Oregon’s standards for comprehensive land use planning; 2) city and county comprehensive land use plans; and 3) state agencies and natural resource laws such as the Oregon Beach Bill and the Removal-Fill Law.

Under the provisions of the CZMA, NorthernStar must provide a certification to the FERC and the ODLCD that the project complies with and will be conducted in a manner consistent with the state’s approved management program (15 CFR 930.50 Subpart D). NorthernStar submitted its federal consistency certification to the ODLCD on December 8, 2006 with a request for a formal determination of consistency. In a letter to NorthernStar dated January 5, 2007, the ODLCD requested additional information before it would begin its consistency review. NorthernStar submitted a revised consistency certification on October 23, 2007. On November 21, 2007, ODLCD determined that its 6-month review period began with the submission of the revised consistency certification. On April 9, 2008, NorthernStar signed a Stay Agreement with the ODLCD that provides a 150-day extension period when NorthernStar can provide the ODLCD with additional information about its project. On May 9, 2008, the ODLCD issued a data request to NorthernStar seeking clarification about project elements. The ODLCD expects to make its decision regarding the project’s consistency with the CZMA on or before September 21, 2008. See section 4.7.2.4 of this EIS for further information regarding compliance with the CZMA.

1.3.10 U.S. Department of Defense Consultation

We have consulted with the U.S. Department of Defense (DOD), as required by the Energy Policy Act of 2005 (EPAct) and section 3 of the NGA, to determine if there would be any impacts associated with the project on military training or activities on any military installations. No comments or concerns were received from any branch of the military or a military installation in response to the FERC's scoping notice issued September 13, 2005.

In letters dated September 23, 2005 and January 11 2006, to appropriate property managers and installation supervisors at the Pentagon representing the Army, Air Force, and Navy, and the COE, we informed various offices of the DOD of the Bradwood Landing Project and requested any information on impacts on military installations. On August 17, 2007, the FERC provided the DOD with copies of the draft EIS, and requested comments. Since no effects have been identified, we conclude that there would be no impact on military installations associated with this project, and therefore, no concurrence from the Secretary of Defense is required under the EPAct.

1.3.11 Other State Permits and Approvals

In addition to the federal permitting authorities that have been delegated to the states, as discussed above, various laws and regulations promulgated by the States of Oregon and Washington have relevance to the Bradwood Landing Project. In addition to the permits, approvals, and consultations listed in table 1.3-1, the Coast Guard worked with representatives of the States of Oregon and Washington in reviewing the WSA for the project.

The FERC encourages cooperation between applicants and state and local authorities, but this does not mean that state and local agencies, through application of state and local laws, may prohibit or unreasonably delay the construction or operation of facilities approved by the FERC. Any state or local permits issued with respect to jurisdictional facilities must be consistent with the conditions of any Certificate the FERC may issue.⁸

Oregon

The ODE is the appropriate state agency designated by the Governor of Oregon to consult with the FERC on state considerations related to the Bradwood Landing Project according to the EPAct. On July 6, 2006, the ODE submitted a safety advisory report to the FERC for its consideration in reviewing the Bradwood Landing Project. On December 6, 2006, the ODE conveyed a Clatsop County Emergency Services Report, and requested that the Commission consider making the provision of resources outlined in the report a condition to the authorization for the project.

Under Oregon's Removal-Fill Law (Oregon Revised Statute (ORS) 196.795-990), permits are issued by the Oregon Department of State Lands (ODSL) for:

- projects requiring the removal or fill of 50 cubic yards or more of material in waters of the state;
- the removal or fill of any material regardless of the number of cubic yards affected in a stream designated as essential salmon habitat; and

⁸ See, e.g., *Schneidewind v. ANR Pipeline Co.*, 485 U.S. 293 (1988); *National Fuel Gas Supply v. Public Service Commission*, 894 F.2d 571 (2d Cir. 1990); and *Iroquois Gas Transmission System, L.P., et al.*, 52 FERC ¶ 61,091 (1990) and 59 FERC ¶ 61,094 (1992).

- the removal or fill of any material from the bed and banks of scenic waterways regardless of the number of cubic yards affected.

All permits include standard and special design and operating conditions that are intended to ensure the protection, conservation, and best use of the state's water resources and to prevent harm to fishery and recreational uses of the waters. A common condition is that the project be conducted during the "in-water work period" established by the Oregon Department of Fish and Wildlife (ODFW) for the specific waterbodies. For projects involving impacts on wetlands, compensatory mitigation to offset loss of wetland resources is required per Oregon Administrative Rule (OAR) 141-085-0121.

A JPA is used for the Oregon Removal-Fill Permit and the COE Permit under section 10 of the RHA and section 404 of the CWA as described above. However, the JPA must be submitted to both agencies and separate permits are issued.

The purpose of the Fish and Wildlife Habitat Mitigation Policy (HMP) (OAR 345-022-0060) is to apply consistent goals and standards to mitigate impacts on fish and wildlife habitat caused by land and water development actions. The policy provides goals and standards for general application to individual development actions, and for the development of more detailed policies for specific classes of development actions or habitat types. In implementing this policy, the ODFW will recommend or require mitigation for losses of fish and wildlife habitat resulting from development actions. Priority is given for native species. Section 4.5.2.4 includes a detailed discussion of NorthernStar's compliance with this policy.

Oregon permits and authorizations relevant to the Bradwood Landing Project are listed in table 1.3-1. On December 18, 2007, the State of Oregon filed consolidated comments on our draft EIS. We address those comments in Appendix K of this final EIS.

Washington

In Washington, state and county agencies conduct environmental reviews of proposed projects pursuant to the State Environmental Policy Act (SEPA) (Chapter 43.21C Revised Code of Washington (RCW)). The SEPA process involves the identification and evaluation of probable environmental impacts, and the development of mitigation measures that will reduce adverse environmental impacts. Cowlitz County is the lead SEPA agency for the Bradwood Landing Project and is responsible for compliance with SEPA procedural requirements as well as for compiling and assessing information on the environmental aspects of the proposal for all agencies with jurisdiction in Washington. As the lead SEPA agency, Cowlitz County is also responsible for the threshold determination⁹ and preparation and content of an EIS when required.

Cowlitz County could adopt this EIS for the Bradwood Landing Project if its independent review confirms that the document is adequate, meets the county's environmental review standards, and the requirements of the State of Washington Administrative Code (WAC) 197-11-610 and 197-11-630. If the county decides to adopt this EIS, it would fill out and circulate the adoption form in WAC 197-11-965 to agencies with jurisdiction and to persons or organizations that have expressed an interest in the proposal. No action may be taken on the proposal until 7 days after the statement of adoption form has been issued. Once the 7-day waiting period is completed, the state and local agencies could begin issuing permits.

⁹ A SEPA threshold determination is the formal decision as to whether or not the proposal is likely to cause a significant adverse environmental impact that requires review in an EIS.

The Growth Management Act was passed in 1990 to address what the Washington State Legislature referred to as uncoordinated and unplanned growth that posed a threat to the environment, sustainable economic development, and the quality of life in Washington. The Growth Management Act requires state mandated comprehensive planning for the most populated and fastest growing counties of the state. Because Cowlitz County is not such a county, it is not subject to most provisions of the act. However, the Growth Management Act also mandates that all counties develop and adopt an ordinance that classifies, designates, and protects critical areas. Cowlitz County has implemented a Critical Areas Ordinance, set forth as Chapter 19.15 of the Cowlitz County Code (CCC). Cowlitz County is currently in the process of updating this ordinance.

Critical areas may contain valuable natural resources; perform important ecological functions and processes; or, if developed, present potential hazards to life and property. In conjunction with other applications, the county reviews critical areas relative to the following:

- Wetlands – Provide numerous valuable functions, including but not limited to providing wildlife and fish habitat, water quality enhancement, flood and erosion control, and aquifer recharge and discharge.
- Geologic hazards – Pose a risk to public and private property and to the natural systems that make up the county’s environment. Such areas are susceptible to landslides, erosion, seismic activity, volcanic activity, or mining hazards. Future developments should be directed to more geologically stable areas and away from unsuitable ground.
- Aquifer recharge areas – Perform many important biological and physical functions that benefit the county and its residents, including storing and conveying groundwater. Protection of aquifer recharge areas is necessary to protect valuable groundwater resources.
- Fish and wildlife habitat conservation areas – Perform many physical and biological functions that include but are not limited to providing opportunities for food, cover, nesting, breeding, and movements for fish and wildlife; maintaining and promoting diversity of species and habitat; and helping to maintain air and water quality.
- Frequently flooded areas – Pose a risk to public and private property and public health. Regulation of these lands promotes efficient use of the land and water resources by allocating frequently flooded areas to the uses for which they are best suited and to discourage obstructions to flood flows.

Designated critical areas affected by the Bradwood Landing Project are identified and discussed in the applicable resource sections in section 4.0 of this EIS.

The Shoreline Management Act was passed by the Washington State Legislature in 1971. The Shoreline Management Act is the principal means of regulating shoreline land and water uses throughout the state and requires cities and counties to develop Shoreline Master Programs (SMP). The WDE reviews and formally adopts the programs. The SMPs must be consistent with statewide policies but contain specific regulations and policies that are tailored to local conditions to promote orderly and reasonable development of waterfront lands. The overall intent is to protect the resources and ecology of Washington’s largest streams, lakes, and marine waters. Shoreline permit decisions are made and issued by local governments; however, the WDE reviews those decisions. In addition, for shoreline conditional use or variance permits, the WDE is responsible for approving, denying, or approving with additional conditions, the local decision.

Requests for shoreline development permits in Cowlitz County are reviewed under the criteria established by the Shoreline Management Act through Cowlitz County's SMP adopted in 1977, and through the authority of Chapter 19.20 of the CCC. Detailed information on the designated shorelines crossed by the proposed pipeline is presented in section 4.3.2.1.

Other Washington permits and authorizations are listed in table 1.3-1. On December 18, 2007, Cowlitz County filed comments on our draft EIS. The Washington Department of Natural Resources (WDNR) provided comments in letters dated December 20, 2007 and January 3, 2008; the WDE commented on December 21, 2007; the WUTC provided comments in a letter dated December 11, 2007; and the Washington Department of Fish and Wildlife (WDFW) filed comments on January 2, 2008. We address these comment letters in Appendix K.

1.4 PUBLIC REVIEW AND COMMENT

The Commission developed its environmental Pre-filing Review Process to encourage the early involvement of interested stakeholders, facilitate interagency cooperation, and identify and resolve issues before an application is filed with the FERC. The FERC issued regulations for our Pre-filing Review Process on October 7, 2005, in Docket No. RM05-31-000, Order No. 665. However, those procedures did not apply to NorthernStar because it came in for Pre-filing before the regulations were issued. Instead, NorthernStar followed preliminary guidance provided by the FERC's Office of Energy Projects (OEP) (prepared on February 10, 2004).

On February 23, 2005, NorthernStar filed a request with the FERC to implement the Commission's Pre-filing Process for the Bradwood Landing Project. On March 7, 2005, the FERC granted NorthernStar's request and established a Pre-filing docket number (PF05-10-000) to place information related to the project into the public record.

The FERC introduced NorthernStar's proposal to various stakeholders by issuing a Pre-filing Process Review Notice on March 18, 2005. This notice was sent to elected federal, state, and local government officials; agency representatives; environmental and public interest organizations; Native American tribes; and local libraries and newspapers.

As part of the Commission's Pre-filing Process, NorthernStar initiated a public outreach program during the preliminary design stage of the project. An article about the proposed project appeared in the Daily Astorian on February 23, 2005. NorthernStar established an internet webpage that described the project, mentioned key management team members, outlined potential environmental impacts, and addressed frequently asked questions. NorthernStar contacted and/or met with federal and state regulatory and resource agencies and interested environmental groups, and took agency representatives on site visits. The general public was given an opportunity to learn more about the project at a series of open houses held by NorthernStar including those in Astoria, Oregon (May 19, 2005), Longview, Washington (September 28, 2005), and Knappa, Oregon (September 29, 2005). The FERC staff also was in attendance at NorthernStar's open houses to answer questions from the public. On May 14, 2005, NorthernStar hosted a public tour of the Bradwood LNG terminal location. NorthernStar presented information about the project to an audience of 125 at a special meeting of the Board of Wahkiakum County Commissioners on May 17, 2005.

TABLE 1.3-1

Major Permits, Approvals, and Consultations for the Bradwood Landing Project

Agency	Authority/Regulation/Permit	Agency Action	Status
FEDERAL			
FERC	NEPA 40 CFR 1500-1508 Sections 3 and 7 of the NGA 18 CFR 380 and Section 311 of EPAct 18 CFR 153, 157, 375, and 385 Order No. 687	Prepare EIS. Issue Approval of Place of Siting, Construction, and Operation of LNG Terminal Facilities (section 3a of NGA). Issue Certificate of Public Convenience and Necessity to construct, install, own, operate, and maintain a pipeline (section 7c of NGA).	FERC issued draft EIS on August 17, 2007. NorthernStar filed applications with the FERC on June 5, 2006.
ACHP	Section 106 of the NHPA 36 CFR 800	Has opportunity to comment on the undertaking.	Pending FERC review of final cultural resources reports, after consultations with State Historic Preservation Offices (SHPO).
U.S. Department of Agriculture, Natural Resources Conservation Service	Farmland Protection Policy Act	Determine if the project would result in the permanent conversion of prime farmland.	Pending.
Coast Guard	33 CFR 127	COTP issues an LOR determining the suitability of the waterway for LNG marine traffic.	NorthernStar submitted LOI to the Coast Guard on January 18, 2005. LOR pending completion of the NEPA review.
	33 CFR 165	Establish safety and security zones for LNG vessels in transit and while docked.	Coast Guard issued WSR on February 28, 2007. NorthernStar issued first annual WSA update on February 28, 2008.
	Ports and Waterway Safety Act Maritime Transportation Act 33 CFR 101, 103, 104, 105	Ensure navigation safety. Develop LNG Vessel Management and Emergency Plan. Review and approve Facility Security Plan.	Pending. Pending.
	NVIC 05-05	Validate WSA and produce WSR.	NorthernStar submitted follow-up WSA to the Coast Guard in May 2006. Coast Guard issued its WSR on February 28, 2007.
COE	Section 10 of the RHA	Issue permit for activities that will occupy, fill, or grade land in a floodplain, streambed, or channel of a stream or other waters of the United States.	NorthernStar submitted its JPA and JARPA to the COE on October 10, 2006; revised JPA on March 2, 2007. NorthernStar withdrew and resubmitted the same JARPA in October 2007.

TABLE 1.3-1 (cont'd)

Major Permits, Approvals, and Consultations for the Bradwood Landing Project

Agency	Authority/Regulation/Permit	Agency Action	Status
	Section 404 of the CWA	Issue permit for the placement of dredged or fill material into waters of the United States, including wetlands.	NorthernStar submitted its JPA and JARPA to COE on October 10, 2006; revised JPA on March 2, 2007. NorthernStar withdrew and resubmitted the same JARPA in October 2007. COE issued its Public Notice on October 18, 2007. COE participated in public meeting on application in February 2008. COE issued information request to NorthernStar on January 14, 2008. NorthernStar submitted responses on February 13 and April 1, 2008.
DOD	Section 311 of the EPA Act and Section 3 of the NGA	Provide information regarding project effects on military installations.	FERC sent letters to DOD dated September 23, 2005, January 11, 2006, and August 17, 2007.
EPA	Section 404 of the CWA	Can veto wetland permits issued by the COE.	NorthernStar submitted its JPA and JARPA to the COE on October 10, 2006; revised on March 2, 2007. NorthernStar withdrew and resubmitted the same JARPA in October 2007. EPA commented on the draft EIS in a letter dated December 19, 2007.
FWS	Section 7 of the ESA	Consider lead agency determination of effects on federally listed species and their habitat. Provide a BO if the project is likely to adversely affect such species or their habitat.	FERC submitted initial BA on March 19, 2007. FWS requested additional information in letter dated April 20, 2007. FERC's revised BA and EFH Assessment in preparation.
	Fish and Wildlife Coordination Act	Provide comments to prevent loss of and damage to wildlife resources.	Pending review of the FERC's revised BA and EFH Assessment.
	Migratory Bird Treaty Act	Review the proposed project for consistency with Executive Order 13186.	Pending review of this final EIS.
NMFS	Section 7 of the ESA	Consider lead agency determination of effects on federally listed species and their habitat. Provide a BO if the project is likely to adversely affect such species or their habitat.	FERC' submitted initial BA March 19, 2007. NMFS requested additional information in letter dated May 11, 2007. FERC's revised BA and EFH Assessment in preparation.
	MMPA 50 CFR 216	Consult on protected marine mammals.	Pending review of the FERC's revised BA and EFH Assessment and this final EIS. NorthernStar intends to apply for an Incidental Harassment Authorization post-FEIS.

TABLE 1.3-1 (cont'd)

Major Permits, Approvals, and Consultations for the Bradwood Landing Project

Agency	Authority/Regulation/Permit	Agency Action	Status
	MSA	Provide conservation recommendations for projects that may adversely impact EFH.	FERC's revised EFH Assessment will be included with revised BA.
DOT, PHMSA	LNG Facilities Petition for Approval	Issue approval that the new LNG facility meets standards governing siting, design, installation, personnel qualifications, and training.	Pending.
	Natural Gas Pipeline Safety Act 49 USC 601 49 CFR Parts 190-199	Administer national regulatory program to ensure the safe transportation of natural gas.	Pending.
U.S. Department of the Treasury, Bureau of Alcohol, Tobacco, and Firearms	Explosives User Permit 27 CFR 555	Issue permit to purchase, store, and use explosives during project construction.	Permit to be obtained by NorthernStar before construction.
STATE – OREGON			
Oregon Department of Agriculture (ODA)	Oregon Endangered Species Act Oregon Senate Bill 533 and Oregon Revised Statute (ORS) 564	Consult on Oregon listed plant species, and ODA would review botanical survey reports covering non-federal public lands where state listed plant species are likely to occur prior to ground disturbing activities.	Pending review of the FERC's revised BA and EFH Assessment and submittal by NorthernStar of preconstruction botanical species surveys.
ODE	Section 311 of the EPAct	Furnish an advisory report to the FERC on state and local safety considerations, and conduct operational safety inspections.	Letters from ODE to the FERC dated July 6, 2006 and December 6, 2006. Consolidated comments of all Oregon agencies on the draft EIS dated December 13, 2007. Provided report on LNG and natural gas review through the Governor on May 9, 2008.
ODEQ	Section 401 of the CWA	Water quality certification.	JPA for water quality and wetlands submitted by NorthernStar on October 10, 2006; revised on March 2, 2007. NorthernStar withdrew and resubmitted the same JARPA in October 2007. Public meeting on permit application held in February 2008.
	Section 402 of the CWA	Issue NPDES permits for discharge of hydrostatic test water, SCV condensate, and stormwater.	NPDES application submitted by NorthernStar on March 8, 2007. ODEQ requested LUCS in letter dated April 18, 2007.
	CAA	Issue air quality permit.	Air Contaminant Discharge Permit application submitted by NorthernStar on March 28, 2007; revised April 9, 2007. ODEQ requested LUCS in letter dated April 10, 2007.

TABLE 1.3-1 (cont'd)

Major Permits, Approvals, and Consultations for the Bradwood Landing Project

Agency	Authority/Regulation/Permit	Agency Action	Status
ODFW	Water Pollution Control Facility Permit under OAR 340-045 and ORS 4688 et seq.	Issue permit for the disposal of solid waste and waste water into public waters, including hydrostatic test water release.	Pending.
	Fish and Wildlife Coordination Act and the Oregon Endangered Species Act under OAR 635 and ORS 496, 506, and 509	Consult on sensitive species and habitats that may be affected by the project and, in general, regarding conservation of fish and wildlife resources. Fish passage approval from ODFW for stream crossings.	Pending review of the FERC's revised BA and EFH Assessment and NorthernStar's submittal of preconstruction fish and wildlife species surveys.
	Fish and Wildlife HMP OAR 345-022-0060	Consult on and approve fish and wildlife mitigation plan.	Pending review of revised Compensatory Mitigation Plan to be submitted by NorthernStar in May 2008.
Oregon Department of Forestry	Oregon Forest Practices Act OAR 629, ORS 477 and 527	Monitors timber harvests on private lands and protects non-federal public and private lands from wildfires.	
ODLCD	CZMA 15 CFR 930 ORS 196.435	Consider consistency with CZMA program policies.	NorthernStar submitted its consistency certification to the ODLCD on December 8, 2006 and submitted a revised consistency certification on October 23, 2007. On November 21, 2007, ODLCD determined that its 6-month review period began with the submission of the revised consistency certification. ODLCD participated in public meeting about application in February 2008. On April 9, 2008 ODLCD signed a Stay Agreement with NorthernStar, adding 150 days to the application review period. ODLCD issued a data request to NorthernStar on May 9, 2008.
SHPO	Section 106 of the NHPA ORS 338.920	Review cultural resources reports and comment on recommendations for NRHP eligibility and project effects. Issue permits for surveys on non-federal public lands and permits for excavations on non-federal public and private lands.	In a letter dated April 4, 2006, the SHPO commented on NorthernStar's first draft survey reports. NorthernStar filed revised reports with the FERC on November 16, 2006, and SHPO commented on those reports in a letter dated November 22, 2006. Final SHPO comments pending NorthernStar's submittal of results of post-Order cultural resources surveys.
ODSL	Submerged and Submersible Land Easement OAR 141-122	Grant submerged land easements (e.g., waterbody crossings).	Pending.

TABLE 1.3-1 (cont'd)

Major Permits, Approvals, and Consultations for the Bradwood Landing Project

Agency	Authority/Regulation/Permit	Agency Action	Status
	Sand & Gravel Lease or License OAR 141-014	Grant lease or license for removal of material (and payment of royalties) in connection with turning basin dredging.	Pending.
	Joint Removal-Fill Permit ORS 196.795-990	Approve removal or fill of material in waters of the state.	JPA submitted by NorthernStar on October 10, 2006 and revised on March 2, 2007. NorthernStar withdrew and resubmitted the same JARPA in October 2007.
	Compensatory Wetland Mitigation Rules OAR 141-085-0121	Review and approve wetland mitigation plans.	Pending review of the revised Compensatory Mitigation Plan to be filed by NorthernStar in May 2008.
Oregon Department of Transportation (ODOT)	Section 303(c) DOT Act 49 CFR 303	Consultation and clearance letter regarding recreational land disturbance and construction-related traffic impacts.	Pending.
Oregon Department of Water Resources (ODWR)	Access Permit ORS 184, OAR 734-051	Issue permits to cross state funded roadways.	Permit application pending.
	ORS 537, OAR 690-310	Issue permits to appropriate surface water and groundwater during project operation.	Applications for Permit to Use Surface Water and Permit to Use Ground Water submitted by NorthernStar on February 28, 2006. ODWR drafted proposed orders on September 4, 2007. Final orders pending.
	ORS 537, OAR 690-340	Issue limited licenses for temporary use of surface waters for hydrostatic testing and suction dredging.	Limited licenses (LL-947, LL-948, LL-949) issued April 25, 2006.
Oregon Public Utilities Commission	OAR 860-031	Inspect the natural gas facilities for safety.	Pending.
STATE – WASHINGTON			
SHPO	Section 106 of the NHPA	Review cultural resources reports and comment on recommendations for NRHP eligibility and project effects.	SHPO commented on definition of area of potential effect (APE) in a January 19, 2006 letter. NorthernStar filed a revised pipeline survey report with the FERC on November 16, 2006. The FERC requested consultation in a letter to the SHPO dated November 24, 2006. SHPO commented on revised report on November 27, 2006. Final SHPO comments pending NorthernStar's submittal of results of post-Order cultural resources surveys.

TABLE 1.3-1 (cont'd)

Major Permits, Approvals, and Consultations for the Bradwood Landing Project			
Agency	Authority/Regulation/Permit	Agency Action	Status
WDE	Section 401 of the CWA	Water Quality Certification.	NorthernStar submitted its JARPA on October 10, 2006 and revised its JARPA in March 2007. NorthernStar withdrew and resubmitted the same JARPA in October 2007. WDE commented on draft EIS in a letter dated December 21, 2007.
	Section 402 of the CWA	Issue NPDES permits for hydrostatic test water discharge and construction stormwater discharge.	NPDES applications to be submitted by NorthernStar prior to construction.
Washington State Department of Labor and Industries	Explosives User Permit WAC 291-52-64005	Issue permit to purchase, store, and use explosives during pipeline construction.	Permit to be obtained by NorthernStar before construction.
WDNR	Forest Practices Act RCW 76.09 and WAC 222	Issue Forest Practices Permit.	Permit application pending. WDNR commented on the draft EIS in letters dated December 20, 2007 and January 3, 2008.
	Aquatic Lands Use and Lease Authorization RCW 79.105 and WAC 332-30	Authorize use of state-owned aquatic lands for waterbody crossings.	Application pending.
Washington State Department of Transportation (WDOT)	State Highway Crossing Permit RCW 47.44 and WAC 468-34	Consider issuance of permits to cross state highways.	Permit application pending.
WUTC	WAC 480-93	Inspect the natural gas pipeline for safety.	Inspections would begin during construction. WUTC commented on the draft EIS in a letter dated December 11, 2007.

TABLE 1.3-1 (cont'd)

Major Permits, Approvals, and Consultations for the Bradwood Landing Project

Agency	Authority/Regulation/Permit	Agency Action	Status
LOCAL			
Clatsop County, Oregon	Multiple Land-use Permits and Approvals	Review consolidated application for compliance with local and state land use plans and regulations. Issue permits and approvals, including LUCS.	Initial consolidated application submitted by NorthernStar in December 2006; supplemental information provided February 2007. County determined application complete on February 14, 2007. County Planning Commission held public hearings on application in July 2007. In August 2007, the Planning Commission recommended approval of the application to the Board of County Commissioners. Board of County Commissioners held public hearings in October 2007. Preliminary approval by Board of County Commissioners in December 2007. Final decision accepting NorthernStar's proposed land use changes made by the Board of County Commissioners on March 20, 2008. County wrote letters to the FERC dated November 12, 2007 and February 22, 2008, and the FERC responded in a letter dated April 4, 2008.
	Section 311 of EPAct	Review and provide consultation regarding NorthernStar's Emergency Response Plan (ERP).	Draft ERP distributed February 2007. Final ERP pending.
Pacific County, Washington	Section 311 of EPAct	Review and provide consultation regarding NorthernStar's ERP.	Draft ERP distributed February 2007. Final ERP pending.
Wahkiakum, Washington	Section 311 of EPAct	Review and provide consultation regarding NorthernStar's ERP.	Draft ERP distributed February 2007. Final ERP pending. Wahkiakum County wrote a letter to the FERC dated December 18, 2007.
Cowlitz County, Washington	SEPA Chapter 43.21C RCW	Complete SEPA review of the proposed project.	County would do SEPA review concurrent with the NEPA review. County submitted comments on draft EIS in a letter dated December 11, 2007.
	Shoreline Management Act	Issue Shoreline Development Permit to cross waterbodies covered by the Shoreline Management Act.	NorthernStar submitted an Environmental Criteria Consistency Evaluation in October 2007.

TABLE 1.3-1 (cont'd)

Major Permits, Approvals, and Consultations for the Bradwood Landing Project

Agency	Authority/Regulation/Permit	Agency Action	Status
All Counties	Critical Areas Ordinance under State of Washington Growth Management Act	Review consistency of the project with the county Critical Areas Ordinance.	NorthernStar submitted an Environmental Criteria Consistency Evaluation in October 2007.
	Floodplain Management Ordinance	Consider issuance of permit to cross floodplains covered by the Floodplain Management Ordinance.	NorthernStar submitted an Environmental Criteria Consistency Evaluation in October 2007.
	Gas and Oil Pipeline Ordinance	Consider issuance of a General Permit under the Gas and Oil Pipeline Ordinance.	NorthernStar submitted an Environmental Criteria Consistency Evaluation in October 2007.
	Forest Lands Conversion Ordinance	Consider issuance of a Class IV-General Forest Practice Permit.	NorthernStar submitted an Environmental Criteria Consistency Evaluation in October 2007.
	Road Crossing Permits	Consider issuance of permits to cross county roads.	Permits to be obtained by NorthernStar before construction.
	Grading Permits	Consider issuance of permits for excavation and grading activities.	Permits to be obtained by NorthernStar before construction.
	Solid Waste Disposal	Consider approvals to dispose of solid waste generated by construction.	Permits to be obtained by NorthernStar before construction.

On September 13, 2005, the FERC and Coast Guard jointly issued a *Notice of Intent to Prepare an Environmental Impact Statement for the Proposed Bradwood Landing LNG Project, Request for Comments on Environmental Issues, and Notice of Joint Public Meeting, and Site Visit* (NOI). The NOI was sent to 1,093 interested parties including federal, state, and local elected officials; government agency representatives; environmental and public interest groups; Native American tribes; local libraries and newspapers; landowners adjacent to the proposed LNG terminal; and property owners along the proposed pipeline route. The FERC's comment period for the NOI closed on October 17, 2005. A total of 60 letters were received during the NOI comment period.

The Coast Guard issued an NOI for preparing an LOR as to the suitability of the Columbia River for LNG marine traffic on September 9, 2005. The NOI requested comments specifically related to the maritime safety and security aspects of the proposed Bradwood Landing LNG facility. The Coast Guard's comment period for the NOI closed on October 6, 2005 and 22 letters were received. These letters were filed with the FERC public record on November 1, 2005.

On September 29, 2005, the Coast Guard and FERC staff conducted a joint public scoping meeting in Knappa, Oregon, to provide an opportunity for the general public to learn more about the proposed project. The meeting also allowed the public to comment on issues to be included in the EIS and issues related to the LOR. Thirty-seven people commented at the meeting. A transcript of these comments is part of the public record for the Bradwood Landing Project and is available for viewing on the FERC internet website (<http://www.ferc.gov>).¹⁰ FERC staff went on a site visit, open to the public, to selected points along the proposed pipeline route and the LNG terminal location on September 29, 2005. The FERC held a public informational meeting in Cathlamet, Washington on October 26, 2005 to answer questions regarding the Commission's Pre-filing and the NEPA review processes and to describe steps the public could take to participate in those processes. Notes from that meeting were placed into the public record for this proceeding.

In addition to the public notice and scoping processes discussed above, the FERC conducted agency consultations or participated in interagency meetings to identify issues that should be addressed in this EIS. On April 7, 2005, the FERC sent letters to the COE, Coast Guard, NMFS, EPA, FWS, and ODE requesting their cooperation in the preparation of the EIS. A letter was also sent to the WDE on June 24, 2005 requesting that they become a cooperating party, and our September 13, 2005 NOI invited any other federal, state, local, or tribal agency with jurisdiction or special expertise with respect to environmental issues to formally cooperate with us. The COE and Coast Guard agreed to be cooperating agencies. The NMFS, EPA, FWS, ODE, and WDE declined our invitation. Nevertheless, various agencies acted in a cooperative manner during the Pre-filing process, engaging in consultations, attending meetings, and filing comments on NorthernStar's draft environmental resource reports. Interagency meetings held during the Pre-filing period that were attended by the FERC staff are listed in table 1.4-1.

Throughout the public scoping period (coinciding with the Pre-filing Review Process) we received comments on a wide variety of environmental issues. Between March 7, 2005 and June 5, 2006, we received 102 letters about the project, including 43 letters from individuals, 18 letters from organizations, 2 letters from an Indian tribe, 12 letters from federal agencies, and 27 letters from state and local agencies. In these letters, the most frequently mentioned environmental topics were safety (15.8 percent of comments); socioeconomics (12.7 percent of comments); and biological resources, particularly with respect to salmon in the Columbia River (19.2 percent of comments). Table 1.4-2

¹⁰ Using the "eLibrary" link, select "General Search" from the eLibrary menu and enter the docket number, excluding the last three digits, in the "Docket Number" field (i.e., CP06-365, CP06-366, CP06-376, and CP06-477). Be sure to select an appropriate date range.

summarizes the environmental issues identified during the Pre-filing public scoping process for the Bradwood Landing Project.

On June 5, 2006, NorthernStar formally filed applications seeking authorizations under section 3(a) and 7(c) of the NGA to construct and operate the Bradwood Landing Project. In response to the FERC's Notice of Application (issued June 15, 2006), a total of 38 parties submitted motions to intervene. Intervenor receive all documentation filed in a proceeding, and have the right to seek rehearing of the Commission's decision. The intervening parties are listed in table 1.4-3. Additionally, between the application's filing date of June 5, 2006 and July 13, 2007, when we finished writing text for the draft EIS, the FERC received 27 letters from individuals, 13 letters from organizations, 3 letters from another LNG developer, 9 letters from members of the U.S. Congress, 3 letters from federal agencies, 7 letters from state or local agencies, and 374 form letters commenting on the project.

After the applications were filed, the FERC staff continued to consult with various federal, state, and local agencies that have regulatory or permitting authorities. The FERC staff participated in a number of post-application interagency meetings, telephone conference calls, and site visits, as shown in table 1.4-1. All of the post-application interagency meetings related to preparation of documentation to comply with the NEPA and other environmental laws and regulations, and are, therefore, exempt from the Commission's ex-parte rules in accordance with section 385.2201(e)(1)(iv). In keeping with the FERC's regulations, notes of all post-application interagency meetings, telephone calls, and site visits were placed into the public record for this proceeding.

The FERC issued a Notice of Availability (NOA) of the draft EIS on August 17, 2007. The NOA established a 120-day period for comments on the draft EIS, ending on December 24, 2007 (later extended to December 26, 2007). A formal notice was also published by the EPA in the Federal Register on August 24, 2007, indicating that the draft EIS was available. The FERC mailed approximately 1,200 copies of the draft EIS to interested parties, including federal, state, and local officials and agencies; special interest groups; parties to the proceedings; area libraries and newspapers; and individuals and affected landowners who requested a copy of the draft EIS.

On October 5, 2007, the FERC issued a notice announcing the time, date, and location of four public comment meetings to take comments on the draft EIS. At the request of the State of Oregon, the FERC added two more public meetings, with details provided in a notice issued on October 25, 2007. Dates and locations of the public meetings are shown in table 1.4-1. A total of about 70 individuals spoke at the public meetings. Transcripts of the six public meetings are part of the public record for the Bradwood Landing Project.

Comments from the public meetings, as well as written comments on the draft EIS submitted by the public and agencies, are provided along with our responses in Appendix K. Excluding the oral comments from the public meetings, the FERC received a total of about 128 individual written letters commenting on the draft EIS (not including attachments, form letters, or filings by the applicants) by the comment closing date of December 26, 2007, including 4 letters from federal agencies, 15 letters from state and local agencies, and 15 letters from non-government organizations. The issues raised in comments on our draft EIS are listed in table 1.4-4. We have made changes in this final EIS, from the draft EIS text, both in response to comments received on the draft EIS and as a result of updated information that became available after issuance of the draft EIS. This final EIS is being mailed to the agencies, individuals, and organizations on the mailing list that is provided in Appendix A, and was submitted to the EPA for formal issuance of a NOA.

Prior to the publication of both the draft and final EIS, the FERC prepared an administrative draft that was distributed in whole or in part to the COE and the Coast Guard for review. Sections of the EIS were written with the cooperation and assistance of these agencies.

TABLE 1.4-1

Public and Interagency Meetings for the Bradwood Landing Project Attended by the FERC Staff

Date	Location	Purpose	Attendees
PRE-FILING MEETINGS			
March 8, 2005	Washington, D.C.	Applicant/Interagency Meeting	FERC, NorthernStar, and ODE

TABLE 1.4-2

**Environmental Issues Identified During the Pre-filing Public Scoping Process
for the Bradwood Landing Project**

Specific Issue/Comment	EIS Section Where Comments are Addressed
PURPOSE AND NEED (3.6 percent of comments)	1.0
Purpose and need for proposed project; economic viability of LNG, natural gas market.	
Environmental costs versus need; local benefits.	
Need for multiple LNG import facilities.	
ALTERNATIVES (7.0 percent of comments)	3.0
Alternative energies and alternative energy sources.	
LNG terminal at alternative onshore sites.	
Alternative pipeline routes.	
Offshore LNG terminal alternatives.	
Alternative LNG storage tank designs and vaporization technologies.	
GEOLOGY (5.5 percent of comments)	4.1
Geologic stability of proposed LNG terminal site; potential for earthquakes and tsunamis.	
Full geotechnical analysis needed.	
Geo-stabilization may need to be increased due to area seismic conditions.	
Potential for flooding to impact project and vice versa.	
SOILS AND SEDIMENTS (2.3 percent of comments)	4.2
Environmental impacts of dredged material placement; best management practices for dredging.	
Potential contamination of soils and sediments.	
Sediment sampling plan is needed.	
Increased erosion due to project.	
Control of the wake from LNG carriers.	
Feasibility of dredging Clifton Channel.	
WATER RESOURCES (7.8 percent of comments)	4.3
Dredging impacts on water quality of Columbia River.	
Impacts on waterbodies (e.g., waterbody crossings); the number of waterbody crossings should be minimized.	
WETLANDS (5.7 percent of comments)	4.4
Impacts on wetlands; wetland delineation required.	
Wetland crossings should be minimized; compensatory wetland mitigation plan should be developed.	
BIOLOGICAL RESOURCES (19.2 percent of comments)	4.5 and 4.6
Direct, indirect, and cumulative impacts on endangered and threatened species, EFH, and other non-listed species.	
Short-term and long-term impacts on fishery resources in Columbia River and Hunt Creek.	
Direct and indirect habitat impacts from dredging and pier construction.	
Impacts on Native American tribal fisheries.	
Project should follow Oregon's Fish and Wildlife HMP.	
BA and EFH Assessment should be prepared.	
Impacts from increased ship traffic, changes in water and air temperature, noise, light, exotic and invasive species, spills of pollutants, and withdrawal of river water.	
LAND USE (4.0 percent of comments)	4.7
Consistency with current land use and zoning.	
Residences are within 0.5 mile of LNG terminal and less than 1,000 feet from LNG carriers.	
Project is within Oregon's coastal zone.	
Impacts on recreation, national historic sites, forestry resources, property rights.	

TABLE 1.4-2 (cont'd)

**Environmental Issues Identified During the Pre-filing Public Scoping Process
for the Bradwood Landing Project**

Specific Issue/Comment	EIS Section Where Comments are Addressed
VISUAL RESOURCES (3.6 percent of comments)	4.7
Visual impacts on residents within 5 miles.	
Alteration/degradation of existing shoreline aesthetic.	
Light pollution.	
SOCIOECONOMICS (12.7 percent of comments)	4.8
Impacts on recreational and commercial fishing, tourism, and property values.	
Additional costs of providing security and emergency response services.	
Project would provide increased revenues and jobs to the area.	
Use of eminent domain; environmental justice issues.	
Economic costs of reduced/constrained shipping on the Columbia River.	
TRANSPORTATION (5.7 percent of comments)	4.8
LNG marine traffic impacts on other ship traffic, railroad traffic, commercial fishing, and recreational boating and fishing.	
Increased vehicle traffic on LNG terminal access road.	
Impacts on local traffic if Astoria Bridge is closed during LNG carrier transits.	
Areas of the LNG carrier safety and security zones need to be defined.	
AIR QUALITY / NOISE (5.5 percent of comments)	4.10
Air emissions from LNG terminal and ships need to address: dust and odors, acidification of regional watersheds, and total air emissions for the life of the project.	
Air quality impacts need to be determined for both Washington and Oregon.	
Impacts of super-cooled air.	
Assess noise impacts on residents within 5 miles of project.	
Accurate assessment of background noise and total noise levels is needed.	
Underwater blasting should be avoided.	
Assess noise impacts (such as pile driving) on aquatic species; provide noise mitigation.	
RELIABILITY AND SAFETY (15.8 percent of comments)	4.11
LNG carrier and terminal are targets for terrorists.	
LNG carrier navigation issues on Columbia River; proximity of populated areas along transit channel; safety and security zone issues.	
Risks and consequences of LNG spill; history of LNG accidents.	
Limited evacuation routes; limited emergency response services.	
CUMULATIVE IMPACTS (1.7 percent of comments)	4.12
Cumulative impacts on biological resources in the Columbia River.	
Cumulative effects for vegetation, wildlife, aquatic species, and their habitats.	
Cumulative impacts on global warming.

2.0 DESCRIPTION OF PROPOSED ACTION

The FERC is the federal agency responsible for authorizing applications to construct and operate onshore LNG import and interstate natural gas transmission facilities. The COE is responsible for issuing dredging and wetland permits for the project. The Coast Guard is responsible for determining the suitability of the waterway for LNG marine traffic. All of the cooperating agencies agree that the action to be studied in this EIS consists of NorthernStar's proposal to construct and operate an LNG import terminal at Bradwood and the related 36.3-mile-long natural gas sendout pipeline connecting the terminal with the Williams Northwest interstate pipeline system. In addition, the EIS will address the potential environmental impacts related to LNG marine traffic in the waterway from the outer limit of the United States territorial sea to the proposed LNG terminal location, including portions of the shoreline within the "Zones of Concern."¹ It will also analyze the environmental impacts associated with the construction and operation of associated nonjurisdictional facilities, including a 1.5-mile-long power line to the LNG terminal.

2.1 PROJECT COMPONENTS

NorthernStar proposes to construct and operate a new LNG import, storage, and vaporization terminal on the southern shore of the Columbia River at Bradwood, Oregon. In addition, NorthernStar proposes to construct and operate a new natural gas pipeline extending from the LNG terminal to an interconnection with the Williams Northwest pipeline north of Kelso, Washington. This project would allow LNG to be imported from areas with natural gas reserves throughout the world to the LNG terminal by ocean-going LNG carriers. The LNG carriers would enter United States territorial waters about 12 nautical miles (13.8 statute miles) off the coast of Oregon and proceed an additional 38 (statute) miles up the Columbia River to Bradwood. At the LNG terminal, the LNG carriers would be berthed and LNG would be unloaded, stored, vaporized back into natural gas, and delivered to the sendout pipeline. NorthernStar's sendout pipeline would convey the natural gas to local users (at Wauna and Port Westward), the local distribution system of Northwest Natural, and the interstate grid through Williams Northwest pipeline system for transportation to markets throughout the Pacific Northwest. No expansions to the Northwest Natural distribution system or Williams Northwest pipeline system would be required to accommodate the new volumes of natural gas to be delivered by the proposed project.

Figure 2.1-1 illustrates the general location of the project. The text below describes LNG carriers, the waterway to the LNG terminal, LNG terminal facilities, pipeline and associated aboveground facilities, and NorthernStar's proposed wetland and habitat mitigation sites. Section 4 of this EIS will address specific environmental resources that may be potentially impacted by the construction and operation of the proposed facilities.

¹ The "Zones of Concern" are described in Enclosure 11 of the Coast Guard's NVIC 05-05. These zones are based on the report *Guidance on Risk Analysis and Safety Implications of a Large Liquefied Natural Gas (LNG) Spill Over Water*, December 2004 (SAND2004-6258) prepared by the U.S. Department of Energy's Sandia National Laboratories. The Zones of Concern are more fully discussed in section 4.11 of this EIS.

Figure 2.1-1
Bradwood Landing Project
 General Project Location

2.1.1 LNG Carriers

There are currently 15 LNG exporting nations, which combined represent about 33 percent of the world's natural gas reserves. According to the FERC's regulations for applications under section 3 of the NGA, NorthernStar is not required to reveal market data about its LNG import terminal. NorthernStar has indicated that it expects to receive LNG shipments from countries around the Pacific Basin, and perhaps from the Middle East. LNG exporting countries in the Pacific Basin include Indonesia, Malaysia, and Australia. At this time, NorthernStar has not identified the specific sources of LNG supplies, or provided details about the specific LNG carriers that would be used to transport the LNG from their source to the proposed LNG import terminal. NorthernStar has stated that it expects about 125 LNG carriers per year to unload cargos at its terminal, with LNG carriers ranging in size from 100,000 to 200,000 m³ in capacity. Because we do not know the point of origin of the LNG shipments, we cannot discuss any details about the trans-oceanic voyages of the LNG carriers on their way to the Bradwood Landing LNG import terminal. The narrative below is general in nature, describing typical attributes of LNG carriers. Additional information on LNG carrier regulations and safety measures is presented in section 4.11.5.

Ships that transport LNG are specially designed to carry cold liquids for long distances. LNG carriers combine features of conventional ship design with specialized materials and systems that can safely contain super-cooled liquids. There are currently about 218 LNG carriers operating world-wide, ranging in capacity from 1,100 m³ to 154,000 m³ (LNG Express, 2007). A typical modern LNG carrier would be about 975 feet long, 12 to 15 stories above water, with a beam of about 140 feet across, and a draft about 39 feet deep. Figures 2.1.1-1 and 2.1.1-2 illustrate typical LNG carriers.

As part of the waterway suitability review process, the Coast Guard used criteria developed by Sandia National Laboratories to define the outer limits of the hazard zones for assessing potential risks associated with the project. The Sandia analysis was based on LNG vessels with a capacity of 148,000 m³. Therefore, the proposed action, including the Coast Guard's issuance of an LOR, is based on the assumption that LNG vessels traveling to the Bradwood Landing LNG facility would have capacities of no greater than 148,000 m³. Should NorthernStar wish to receive larger LNG vessels in the future, the Sandia analysis would have to be revisited to determine any changes to the Sandia hazard zones, the WSA/WSR would have to be reviewed to determine if the safety and security measures are adequate to accommodate the larger LNG vessels, and supplemental review under NEPA and other applicable laws and regulations would be required.

2.1.1.1 Profile

LNG carriers have a distinctive appearance compared with other transport ships. An LNG carrier has a high freeboard (i.e., that portion of the ship above water) when compared with vessels such as an oil tanker because of the comparatively low density of the cargo. Because of the high freeboard, wind velocity can adversely affect the maneuverability of the ship, particularly at slow speed, such as during docking.

2.1.1.2 Hull System

All LNG carriers are constructed with double hulls, which increases the structural integrity of the hull system and provides protection for the cargo tanks in case of an accident. The space between the inner and outer hulls is used for water ballast. The segregated ballast tanks prevent ballast water from mixing with any residue in the cargo tanks. The International Maritime Organization's (IMO) *Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk* and Coast Guard regulations require that LNG carriers meet a Type IIG standard of subdivision, damage stability, and cargo tank location.

This information is for environmental review purposes only.

Figure 2.1.1-1
Bradwood Landing Project
LNG Carrier with Membrane Type Containment System

Typical Membrane Design for an LNG Vessel

Typical Spherical Design for an LNG Vessel

This information is for environmental review purposes only.

Figure 2.1.1-2
Bradwood Landing Project
Typical Designs for an LNG Carrier

The Type IIG design ensures an LNG carrier could withstand flooding of any two adjacent compartments without any adverse effect upon the stability of the ship. Type IIG design also requires that the cargo tanks must be a minimum of 30 inches from the outer hull and a minimum distance above the bottom of the ship equal to the beam of the ship divided by 15, or 6.5 feet, whichever is less. This distance is intended to prevent damage to the cargo tanks in case of low energy-type accidents that might occur in harbors and during docking. Most large LNG carriers have a distance of 10 to 15 feet between the outer hull and cargo tank.

2.1.1.3 Containment Systems

The LNG containment system on LNG carriers consists principally of the cargo tank (sometimes called a primary barrier), the secondary barrier, and insulation. The containment system also includes cargo monitoring and control and safety systems.

Three basic tank designs have been developed for LNG cargo containment: prismatic free-standing, spherical, and membrane. The earliest form of LNG containment is the prismatic free-standing tank. It consists of an aluminum alloy or 9 percent nickel steel, self-supporting tank that is supported and restrained by the hull structure. Insulation consists of reinforced polyurethane foam on the bottom and the sides, with fiberglass on the top. The spherical tank design, also known as the Moss design, uses an unstiffened, spherical, aluminum alloy tank that is supported at its equator by a vertical cylindrical skirt, with the bottom of the skirt integrally welded to the ship's structure. This free-standing tank is insulated with multi-layer closed-cell polyurethane panels. In the membrane containment system, the membrane is supported by the inner hull through the insulation. Two forms of membrane are commonly used: the Technigaz membrane using stainless steel and the Gas-Transport membrane using Invar. An LNG carrier with a membrane type containment system is shown on figure 2.1.1-1. Figure 2.1.1-2 depicts typical spherical and membrane designs for LNG vessels.

2.1.1.4 Pressure/Temperature Control

A basic goal of all LNG containment systems is to maintain the LNG cargo at or near atmospheric pressure and at the boiling temperature of the LNG (about -260 °F). Any heat leak through the containment insulation results in vaporization of LNG, allowing the tank to remain at a constant temperature. The resultant vapor, referred to as BOG, is removed to maintain the tank pressure. The vapor ranges from 0.15 to 0.25 percent (by volume) per day and is used to supplement the bunker fuel in the ship's boilers. The Coast Guard does not permit routine venting of BOG to the atmosphere in the United States. Thus, all LNG carriers that trade in the United States are fitted with an internalized combustion energy system that allows the ship's boiler to consume all of the BOG to fuel the ship's steam propulsion system. As a result, LNG carriers have reduced emissions when compared with conventional oil-fired ships.

2.1.1.5 Ballast and Cooling Water

Sufficient ballast water capacity must be provided to permit the ship to return to the loading port safely under various sea conditions. LNG cargo tanks are not used as ballast tanks because these tanks remain at cryogenic temperatures and contain a minimal amount of LNG during the return voyage. Consequently, LNG carriers must be designed to provide adequate ballast capacity in other locations.

Ballast water tanks are arranged within the LNG carrier's double hull. To reduce the potential for leakage, the ballast tanks, cofferdams, and void spaces are typically coated to reduce corrosion. LNG carriers are also periodically inspected to examine the coating and to renew it as necessary.

A ballast control system, which permits the simultaneous ballasting during cargo transfer operations, is also incorporated into each LNG carrier. This allows the LNG carrier to stay within a specific range of drafts during all phases of its operation. Under normal operating conditions, ballast water would be taken onto the ship while the LNG carrier is offloading at the LNG import terminal. Ballast water is typically only discharged during loading operations at the LNG export terminal or during mid-ocean ballast water exchanges during the transit from the import terminal to the export terminal. No ballast water would be discharged near the LNG import terminal.

LNG carriers unloading at LNG terminals also need cooling water for the engines that generate electrical power for the offloading pumps and other onboard systems. A combined 20 to 50 million gallons of ballast and engine cooling water is typically taken on during LNG carrier offloading operations. For the Bradwood Landing Project, NorthernStar would construct and install a system capable of delivering filtered river water to the LNG carriers. This system would use a screened water intake located at the ship berth (see figure 2.1.3-3) that would avoid the entrainment and impingement of juvenile fish. The intake water supplied to the LNG carrier would be provided through one of two arrangements. In one arrangement, water supplied to the system would be used first to fill the ballast tanks. Water would then be circulated from the ballast tanks to cool the engines and then returned to the ballast tanks. This arrangement would be used in cases where there are concerns of high static head pressure on the cooling water circuit components. Alternatively, water supplied to the system would be first used to cool the engines and then sent to the ballast tanks. Each of these arrangements provides the benefit of minimizing the total water intake and avoiding discharge of warm water to the Columbia River. In rare instances when the ballast tanks fill before the need for shore-based cooling water is over, the ballast water would be circulated through the engines for cooling after the shore-based water supply is turned off, until the ship is ready to leave the wharf.

NorthernStar has stated it would offer reasonable contract incentives to the LNG suppliers to retrofit the LNG carriers with the piping and equipment necessary to connect with the filtered water supply. The extent of the required modifications would vary depending on the age of the LNG carrier and its type of propulsion (i.e., steam or diesel). In cases where LNG carriers calling at the proposed Bradwood Landing terminal are not properly retrofitted to use the berth's filtered water intake system, NorthernStar would develop appropriate performance standards and detailed operating procedures. We are recommending that NorthernStar develop a plan for delivering screened cooling and ballast water to LNG carriers at the Bradwood Landing terminal. This issue is discussed in more detail in section 4.5.2.1.

2.1.1.6 Ship Safety Systems

The LNG carriers proposed for use in this project would need to comply with all federal and international standards regarding LNG shipping. As such, ships that transport LNG to the proposed import terminal would be fitted with an array of cargo monitoring and control systems. The systems include provisions for pressure monitoring and control, temperature monitoring of the cargo tanks and surrounding ballast tanks, emergency shutdown (ESD) of cargo pumps and closing of critical valves, monitoring of tank cargo levels, and gas and fire detection.

The ships that transport LNG to the terminal would be fitted with many navigation and communication systems, including:

- two separate marine radar systems, including automatic radar plotting;
- automatic identification system;
- communication systems in accordance with the Global Maritime Distress and Safety System;
- echo depth finders; and
- global positioning system for navigation.

All LNG carriers also have redundant, independent steering control systems that are operable from the bridge or steering gear room to maintain rudder movement in case of a steering system failure.

2.1.1.7 Fire Protection

All LNG carriers arriving at the proposed terminal would be constructed according to structural fire protection standards contained in the *International Convention for the Safety of Life at Sea* (SOLAS). This would be done under the review and approval procedures of the Coast Guard.

LNG carriers using the terminal would also be fitted with active fire protection systems that meet or exceed design parameters in Coast Guard regulations and international standards, such as the *Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk* and SOLAS including:

- a water spray (deluge) system that covers the accommodation house and central room, and all main cargo control valves;
- a traditional fire suppression system that provides water to fire monitors on deck and to fire stations found throughout the ship;
- a dry chemical extinguishing system for LNG fires; and
- a carbon dioxide (CO₂), Halon, or equivalent fixed inert gas extinguishing system for protecting the machinery, ballast pump room, emergency generators, cargo compressors, etc.

According to the OWRD (Appendix K, comment SA1-38), use of water for testing fire suppression systems would require a permit from the OWRD, but use of water for firefighting does not require a permit.

2.1.1.8 Crew Qualifications and Training

All officers and crews of the LNG carriers would comply with the *International Convention Standards of Training, Certification and Watch Keeping for Seafarers*. Key members of the crew must have specific training in the handling of LNG and the use of the safety equipment. Officers must receive simulator training in the handling of the carrier and the cargo systems specific to the conditions at the project site. In addition, each LNG carrier would enter the Columbia River under the navigational control of a Columbia River Bar Pilot. Upon transiting past the Astoria-Megler Bridge, a Columbia River Pilot would take navigational control from the Columbia River Bar Pilot.

2.1.1.9 Ship Selection

The specific identity of LNG carriers that would unload at the terminal would depend on the commercial terms of the LNG purchase agreements. Transportation could be provided by either the LNG buyer or supplier. The different contractual arrangements for LNG transport can result in carriers of different sizes and countries of origin being used to transport LNG to the project. The Coast Guard would restrict the size of the LNG carriers operating on the Columbia River to a maximum cargo size of 148,000 m³ until additional risk analyses addressing larger vessels have been completed (see section 4.11.5).

Carriers using the terminal would comply with the Coast Guard regulations for LNG carriers. This compliance is demonstrated by the operator of the LNG carrier having proper certificates authorizing the transport of LNG as follows:

- United States Flag LNG Carrier – The Coast Guard Certificate of Inspection (COI) must be valid and endorsed for the carrier to transport LNG (46 CFR 154). A Coast Guard COI is issued for a period of 5 years and retention of the COI depends upon the continued maintenance of the vessel in a safe operating condition and satisfactory completion of required annual inspections during the 5-year COI period.
- Foreign Flag LNG Carrier – The carrier must have a valid Certificate of Compliance (COC) issued by the Coast Guard. The certificate is issued after the carrier has proved that it complies with the Coast Guard regulations and after it has been satisfactorily inspected by a Coast Guard Marine Safety Office (46 CFR 154). A COC is valid for a 2-year period and remains valid pending satisfactory completion of an annual mid-period examination between certificate renewals.

Both United States and foreign flagships must be annually inspected by the Coast Guard and the flag state. Coast Guard officers from Sector Portland, Oregon would be responsible for boarding the LNG carriers prior to the Columbia River Bar crossing to perform security inspections and to assure compliance with safety standards. NorthernStar would continually monitor unloading operations at the LNG terminal to ensure that the operations are according to their established procedures and to ensure that the carriers are maintained to safety standards.

2.1.2 Waterway for LNG Marine Traffic

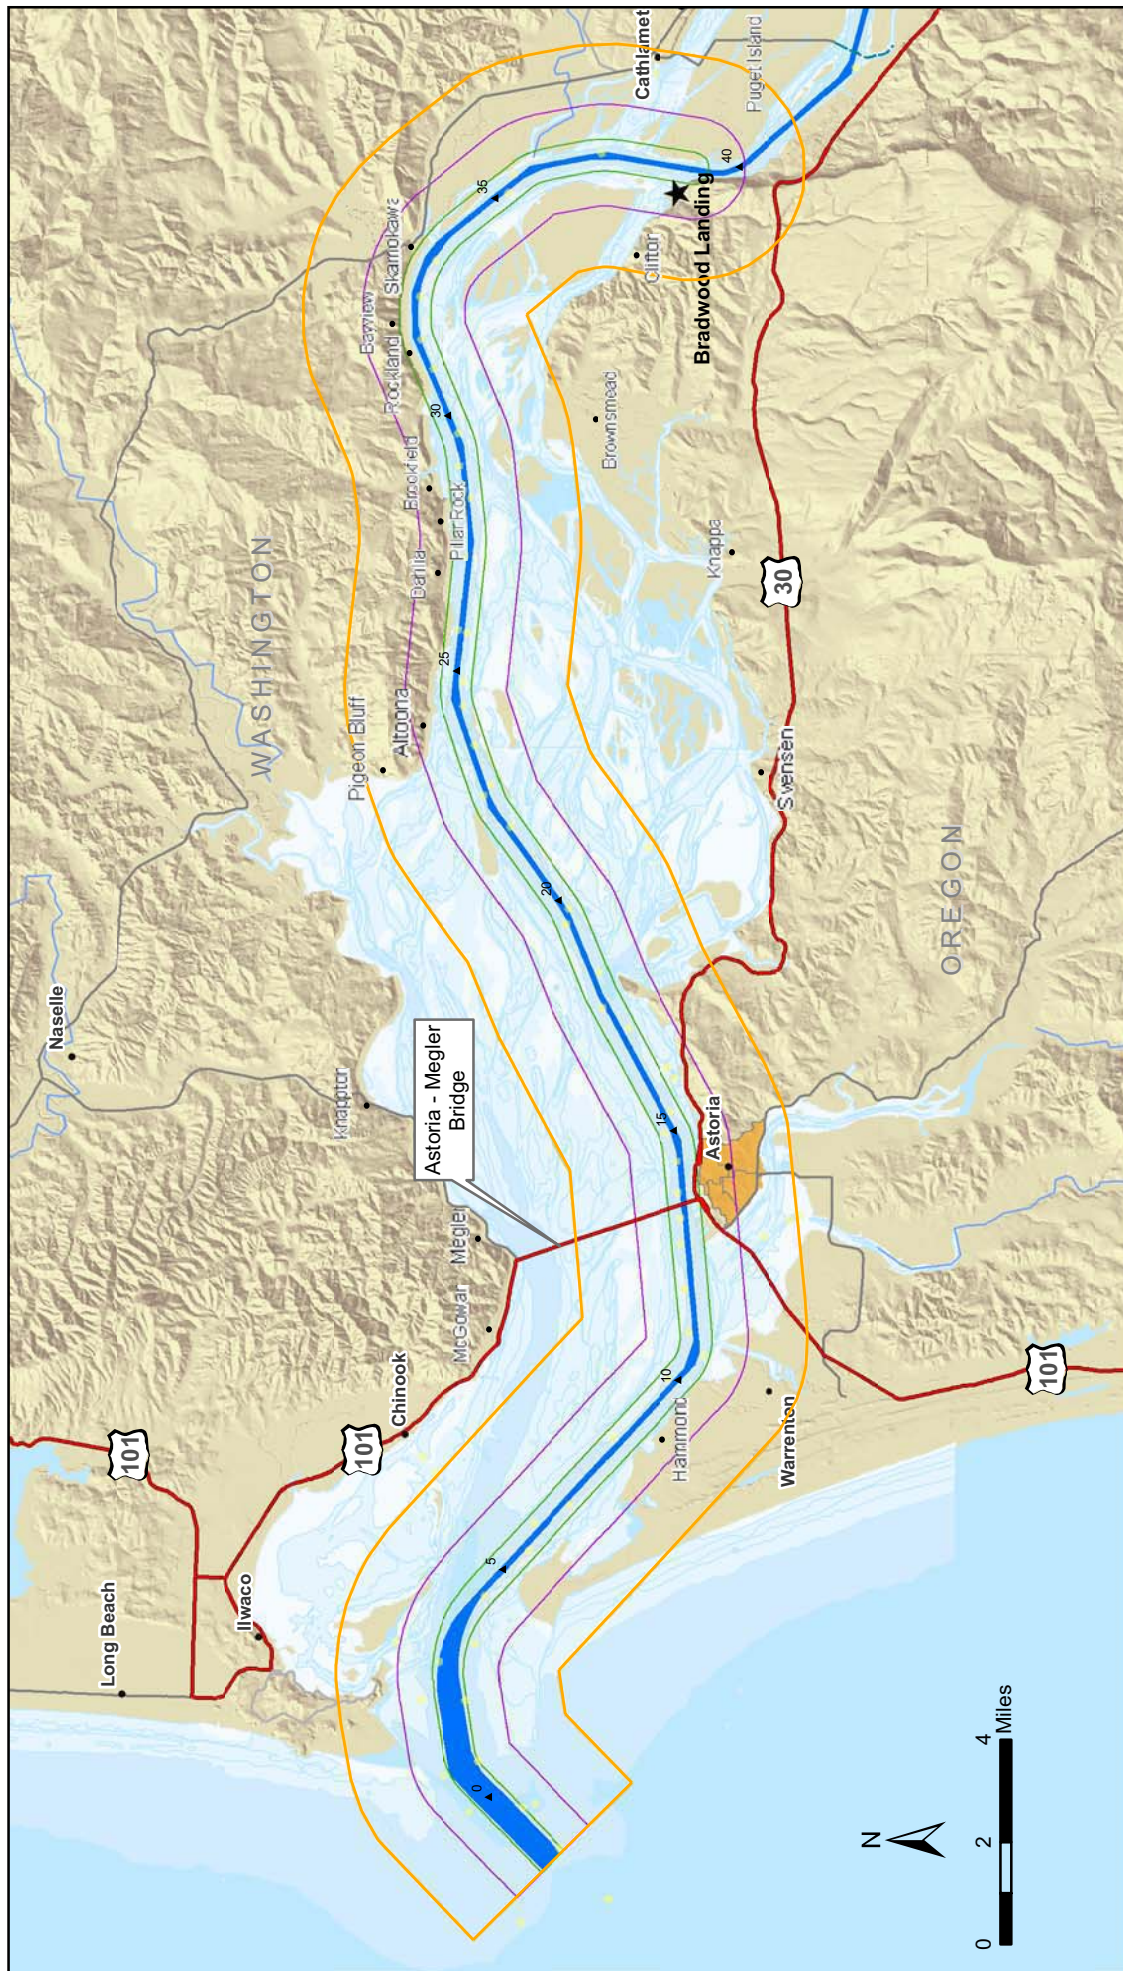

The Coast Guard defines the waterway for LNG marine traffic for this project as extending from the outer limits of the United States territorial waters, 12 nautical miles off the coast of Oregon, and up the Columbia River about 38 miles to the proposed location of the Bradwood Landing LNG import terminal (see figure 2.1.2-1). The Columbia River has an existing dredged federal navigation channel all the way to Portland, Oregon. Improvements to the navigation channel have recently begun to increase the depth to 43 feet; these improvements are expected to be completed before the proposed LNG terminal would go into operation. The COE completed an EIS for its Columbia River dredging project in 1999, which was supplemented in 2003 (COE, 1999; 2003).

2.1.2.1 Waterway Characteristics

The Columbia River originates in British Columbia, Canada, and flows some 745 miles south and west to empty into the Pacific Ocean west of Astoria, Oregon. The federally-maintained navigation channel extends from the mouth up the Columbia River about 104 river miles to Portland, Oregon and Vancouver, Washington and also extends about 12 river miles up the Willamette River at Portland (Port of Portland, 2007a). Near its mouth (Columbia River Mile (CRM) 3) the navigation channel is 600 feet wide and 40 feet deep, as a result of a federal channel deepening project completed in 1976. Along its navigable route there are commercial ports at Astoria, St. Helens, and Portland, Oregon, and Longview, Woodland, Kalama, and Vancouver, Washington. The COE dredged about 28 miles of the Columbia River channel to 43 feet deep in 2005 (Port of Portland, 2007b). Recent navigation charts published by the COE indicate that water depths adjacent to the proposed LNG terminal site range from 22 feet to over 50 feet.

Tides

Average tides on the Columbia River range from 6.6 feet at Tongue Point, east of Astoria, Oregon to 3.3 feet at Longview, Washington. Tides are a specific consideration in scheduling the entry and exit of deep-draft ships into and out of the river. Downstream of CRM 40, ocean tides control surface water elevations, but river discharges have little effect.

Currents and Freshets

Currents at the Columbia River Bar can be significant, with sudden and unpredictable changes. Ebb currents on the north side of the bar attain velocities of 6 to 8 knots. In the entrance, the currents are variable, and at times reach a velocity of over 5 knots on the ebb; on the flood they seldom exceed a velocity of 4 knots. Ebb currents of 1 to 3 knots occur elsewhere in the river. The current velocity at the proposed LNG terminal is normally about 1 knot.

The current can increase considerably during freshets, the seasonal influence of river flow as continental snowfall melts and drains into the river. The annual high-water freshet stage occurs on the Columbia River in late May. The COE monitors river depth for possible bottom changes that might affect shipping. In addition, the Northwest River Forecast Center has six stage recording stations on the Columbia River to predict river stages up to 6 days in advance, for the use of pilots.

Weather and Ice

Incidents of rain and fog are greater at the mouth of the Columbia River. Winds are channeled by topography to follow the river. Wind direction is generally from the east through southeast in winter, and wind speeds reach 20 miles per hour or more about 5 to 10 percent of the time. Visibility is diminished by fog to below 0.5 mile about 3 to 6 days per month. Winds during the summer remain west to northwest and are typically light. Ice forms occasionally on the river but is seldom heavy enough to affect navigation.

2.1.2.2 Natural Hazards in the Waterway

The Columbia River Bar is located at the mouth of the Columbia River where the current dissipates into the Pacific Ocean, depositing sediments as the river slows. Characterized by the frequent presence of large, standing waves, the Columbia River Bar is exposed to the full force of storm-generated swells and wind waves from winter weather off the Pacific Ocean. The large ocean waves are further accentuated by the fact that they are entering shallow water, and during ebb tides the opposing current builds them further into a standing wave that can approach 35 feet in height. These large swells present several dangers to ship traffic. If they are too large they can overpower the steering ability of the ship, making it impossible to control. In some circumstances the heavy seas that roll on deck create a hazard to structures and equipment. A deeply loaded ship can pitch and roll so heavily that striking the bottom in a trough becomes a concern. During storm conditions, the Columbia River Bar Pilots will not transit a vessel across the bar if conditions are unsafe.

Geographic hazards characterizing the local marine environment include shallows and shoaling in way of the approaches and vicinity of Lower and Upper Desdemona Shoals, Harrington Point Range, Miller Sands Range, Pillar Rock (Lower and Upper), Welch Island Reach, Skamokawa Channel, Steamboat Reach and Puget Island Range and Turn. Characteristics that contribute to natural hazards are largely a function of channel width and natural constraints (i.e., sand, rock, and depth) defining the lateral edges of the channel.

Bar pilots consider two factors relating to how physical conditions in the Lower Columbia River affect transit: 1) wave conditions at the river mouth, and 2) underkeel clearance in the channel between CRM 6 and 13, which is susceptible to shoaling. Safe conditions at the river mouth would be when waves are less than 10 feet high, a condition that exists about 95 percent of the time. Entrance to the channel would be closed to ships with drafts of 36 feet for about 960 hours per year based on wave forecasts. Ships with drafts deeper than 36 feet must schedule departure from upriver ports to arrive at

Astoria during required tide conditions. About half of the 40-foot draft ships must delay departures to wait for suitable tide stages in the estuary.

The ports along the Columbia River are primarily protected from the high seas by topographical features and characteristics of the mouth of the river. Key features include Clatsop Spit on the south side of the mouth and Cape Disappointment on the north. Additional protection is offered on the south by the South Jetty. This jetty is a manmade artifice running generally westerly from Clatsop Spit for a distance of approximately 2 miles. Protection on the north side of the mouth is offered by the North Jetty, which is a manmade artifice running generally westerly from the southwestern tip of Cape Disappointment for a distance of approximately 0.5 mile. The protection from the high seas becomes apparent along the navigation channel southeast of CRM 5 and in the partially protected waterway more enclosed by Clatsop Spit and the Washington State coastline on the south and north, respectively.

2.1.2.3 Human-Created Obstructions in the Waterway

There is only one bridge across the Columbia River between its mouth and Bradwood. The Astoria-Megler Bridge along U.S. Highway 101 connects Astoria, Oregon with Point Ellice, Washington. The bridge is 4.1 miles long, and when completed in 1966, it was hailed as the longest continuous truss in the world. Over the navigation channel this bridge has an air clearance 205 feet high and 1,070 feet wide. No power lines cross over the river along the route to the proposed LNG terminal.

2.1.2.4 Aids to Navigation in the Waterway

There are two anchorages adjacent to Astoria, the Astoria North Anchorage and the Astoria South Anchorage. The anchorages are located on either side of the ship channel. Anchorages are used for temporarily locating ships before proceeding upstream or to sea. All designated anchorages are primarily used to accommodate ships over 200 feet in length. However, these anchorages would not be suitable for use by LNG carriers. Anchorages for LNG carriers along the LNG marine waterway would not be necessary because an LNG carrier would not enter the Columbia River if the berth at the LNG terminal was not available and would not depart the terminal if the bar was likely to be closed. There is also a turning basin at Astoria.

The COE has installed fields of timber piles to control channel alignment for navigation and provide bank protection. The COE maintains 236 pile dike fields along the entire length of the Columbia River navigation channel. In addition, the COE has used in-water dredged fill material to reduce the channel cross-section. Upstream of CRM 20, nearly half the shoreline of the channel is composed of dredged fill material. Dredged material has also been used by the COE to create islands to control channel alignment. These islands are usually protected by pile dike fields.

2.1.2.5 Current Marine Traffic on the Waterway

Currently, ships using the Columbia River transport both foreign and domestic cargoes. Exports include logs, lumber, forest products, grain, flour, chemicals, fruit, fish, general and containerized cargo, and general merchandise. Imports include coal, petroleum products, bulk salt, bulk cement, alumina, manufactured products, and general and containerized cargo. About 1,700 commercial ships were counted entering the Columbia River in 2003. Most commercial traffic would proceed past the proposed LNG terminal on their way to ports up river, with the exception of cruise ships that stop at Astoria during the summer.

The Columbia River is also visited by commercial and recreational fishing boats. It has been estimated that Oregon and Washington anglers combined made over 400,000 total fishing trips on the

lower Columbia River (from Bonneville Dam to Buoy 10) in 2005 (ODFW, 2006b). Marinas serving boaters on the Lower Columbia are located at Hammond, Warrenton, and Astoria in Clatsop County, Oregon; Rainer in Columbia County, Oregon; Ilwaco in Pacific County, Washington; Cathlamet in Wahkiakum County, Washington, and Longview and Kalama in Cowlitz County, Washington.

2.1.2.6 Safety Measures Currently in Place for Existing Vessel Traffic

With the exception of recreational and fishing vessels, all ships over 100 feet in length moving up or down the Columbia River must be accompanied by a licensed pilot. Pilotage service is provided by the Columbia River Bar Pilots from the boarding area offshore to Astoria, and by the Columbia River Pilots for river transits east of Tongue Point.

2.1.2.7 Population Adjacent to the Waterway

The Warrenton/Astoria area in Clatsop County, Oregon, is the major population center along the LNG marine traffic route. In 2006, the population of Warrenton was estimated at 4,460, while about 9,970 people resided in Astoria. The majority of the shoreline along the LNG marine traffic route is rural, and sparsely populated. In Wahkiakum County, Washington, Cathlamet is the largest town, with a population estimated at 555 in 2006. About 800 people live on Puget Island.

2.1.2.8 Coast Guard Review of Waterway Suitability for LNG Marine Traffic

The Coast Guard is responsible for issuing an LOR regarding the suitability of the waterway for LNG marine traffic. Following the guidance in NVIC 05-05, NorthernStar produced a WSA that was reviewed and validated by the Coast Guard. During the validation process, the Coast Guard consulted with a variety of stakeholders, including state and local emergency responders, marine pilots, towing industry representatives, members of the Port Waterway Safety Committee, and the Area Maritime Security Committee. The WSA is designated as Sensitive Security Information as defined in 49 CFR 1520. Because any unauthorized disclosure of these details could be employed to circumvent the proposed security measures, they are not releasable to the public, and the WSA is not a part of the FERC public record in this proceeding.

The Coast Guard issued its WSR for this project on February 28, 2007 (see Appendix G). The COTP indicated in the WSR that in order to make the Columbia River suitable for LNG marine traffic additional measures would be necessary to responsibly manage navigation, safety, and security risks. These measures are discussed in detail in section 4.11.5.4.

As previously indicated, the Coast Guard used criteria developed by Sandia National Laboratories to define the outer limits of the hazard zones for assessing potential risks associated with the proposal as part of the waterway suitability review process. Because the Sandia analysis was based on LNG vessels of 148,000 m³, the proposed action, including the Coast Guard's issuance of an LOR, is based on the assumption that LNG vessels traveling to the Bradwood Landing LNG facility would have capacities of no greater than 148,000 m³. Should NorthernStar wish to receive larger LNG vessels in the future, the Sandia analysis would have to be revisited to determine any changes to the Sandia hazard zones, the WSA/WSR would have to be reviewed to determine if the safety and security measures are adequate to accommodate the larger LNG vessels, and supplemental review under NEPA and other applicable laws and regulations would be required.

2.1.3 LNG Terminal Facilities

The LNG import terminal facilities would include an LNG carrier turning basin/maneuvering area in the Columbia River, berth and unloading facilities, two LNG storage tanks, vaporization and vapor handling systems, and support facilities. The terrestrial portion of the LNG terminal would occupy about 40 acres of land within a 411-acre site controlled by NorthernStar. A layout of the proposed LNG terminal is provided on figure 2.1.3-1.

2.1.3.1 Maneuvering Area and Berth

The maneuvering area and turning basin would be approximately 2,000 feet by 2,000 feet in size, covering about 58 acres in the Columbia River off of the existing navigation channel northeast of Bradwood. Only about 46 acres of the 58-acre maneuvering area would require dredging. The remainder is area that would be occupied by the berthing structures or is naturally deep. At this point the navigation channel is 600 feet wide and 40 feet deep; however, the channel is in the process of being deepened to 43 feet by the COE. The final design for the maneuvering area and turning basin was adopted after NorthernStar considered the results of a vessel maneuvering simulation study conducted in 2005 at the COE Engineering Research and Development Center Ship and Tow Simulator in Vicksburg, Mississippi (Waterway Simulation Technology Inc. (WST), 2005).

In order to create the maneuvering area, NorthernStar would dredge approximately 700,000 cubic yards of sediments from the Columbia River bottom, allowing for a 1-foot overdredge to -43 feet Columbia River Datum (CRD) (see figure 2.1.3-2). Additional information on the dredging associated with the proposed project is presented in section 2.4.1.2.

The berth at the LNG terminal would be located about 1,200 feet away from the existing navigation channel in the Columbia River. It was designed to handle LNG carriers with cargo capacities ranging from 100,000 to 200,000 m³. The terminal would be capable of offloading one LNG carrier at a time. NorthernStar anticipates that its terminal would be visited by about 125 LNG carriers per year, with an average of 10 to 11 ships per month. Typically, it would take less than 24 hours for an LNG carrier to dock at the terminal, unload, and depart from the berth.

Maneuvering and docking of LNG carriers would be accomplished with three 60-ton bollard pull Z-drive tugboats, which would be operated by a third party marine services provider. The WSR requires that all three tugs would remain on standby while an LNG carrier is unloading; either moored along side or tied to a nearby mooring dolphin.

The ship berth would be approximately 36 feet wide and 330 feet long and would extend into the Columbia River a total of about 300 feet from the shore to the outer edge of the unloading platform. Figures 2.1.3-3 and 2.1.3-4 depict a plan and cross section of the berth. The berth would include four breasting structures, six mooring dolphins, an unloading platform, and a pipeway/roadway trestle from the unloading platform to the shore. The platform would be constructed of reinforced concrete beams and slabs supported on steel piles. A control office would be located on the berth platform to monitor carrier unloading operations, including a display screen to track the velocity and angle of approach of the LNG carrier to the berth. An instrument and communication cable would connect the office instrument control system to the LNG carrier's unloading control system.

MUDLINE	-42.0'

Figure 2.1.3-4
Bradwood Landing Project
Ship Berth Cross Section

The breasting structures and mooring dolphins would be constructed of steel pipe piles with concrete caps. The breasting structures would be equipped with fenders. Quick-release hooks would be provided on the mooring dolphins for the bow and stern breast lines to hold the LNG vessel onto the berth. The mooring hooks would have strain gauges that send data on mooring line tension to the berth control office. The extreme up and downriver mooring dolphins would have navigation lights marking the extent of the structure in the river. Other floodlighting at the berth would be angled downward and shielded, so as not to affect other vessel traffic in the navigation channel and to reduce stray light shining into the water. Catwalks would connect the platform to the wharf head and to the mooring structures. Ladders would be installed on the mooring structures to provide access for small craft docking at the facility.

A small craft berth would be provided against the northwest mooring dolphin. The water around the berth is of sufficient depth to handle the shallow drafts of tugboats and other small service craft that may need to dock at the berth, so no additional dredging would be necessary in this area.

The wharf head would be a reinforced concrete beam structure, about 115 feet wide by 125 feet long, supported by steel pipe piles. The approachway would be about 20 feet wide, to permit a small mobile rubber-tired crane to transit to the unloading arms. The pipeway would be about 19 feet wide. Outside of the pipework, the deck of the approachway and wharf head would be sloped to allow storm-water to run off into the river. The pipework area would be curbed and underlain by a concrete trough to collect an LNG leak or spill and convey the liquid to an onshore spill containment pit.

Table 2.1.3-1 summarizes the location, number, length, diameter, and water depth of piles that would be used to construct the marine terminal.

TABLE 2.1.3-1

2.1.3.2 Unloading and Transfer Facilities

Once berthed, pumps onboard the LNG carrier would deliver LNG through unloading arms and transfer pipelines to the onshore LNG storage tanks. Dockside personnel would connect the unloading arms to the ship manifolds. Cool-down of the unloading arms would be started by introducing a small LNG flow, either using a bypass line around the discharge of one of the carrier's pumps or using a

dedicated small capacity pump on the carrier, through the unloading arms and into the carrier berth KO drum.

The unloading platform at the ship berth would include four 16-inch-diameter cryogenic marine unloading arms. Two of the arms would be dedicated for unloading LNG to the transfer pipelines, one would be for vapor return to the LNG carrier, and one would be a hybrid arm usually used for unloading but also capable of returning vapor as a backup. Each unloading arm would be fitted with powered emergency release coupling valves to isolate the arm and the carrier in the event of a non-scheduled separation and to minimize LNG spillage. Each arm would be operated by a hydraulic system and a counterbalance weight would be provided to reduce the deadweight of the arm on the shipside connection and to reduce the power required to maneuver the arm into position.

The berth and unloading facilities would be designed in accordance with applicable codes and standards, including but not limited to the Oil Companies International Marine Forum, Society of International Gas Tanker and Terminal Operators, International Navigation Association, American Petroleum Institute (API), and American Society of Civil Engineers, to ensure the safe transfer of LNG from the ships to the onshore storage tanks. The LNG unloading rate would be controlled from the carrier. The unloading arms would have a combined unloading rate capacity of 12,000 m³/hour (52,834 gallons per minute (gpm)). It would take about 14 hours to unload a 160,000 m³ capacity LNG carrier.

LNG would be transferred via the unloading arms from the carrier at berth to the LNG storage tanks onshore by cryogenic pipelines that run from the unloading platform down the approachway to the wharf head. The transfer pipeline system would be composed of a 32-inch-diameter LNG unloading line and a 6-inch-diameter LNG recirculation cool-down line. These pipelines would be approximately 800-feet-long from the unloading manifold to the point where the 32-inch-diameter unloading line would divide. One branch of the unloading line would proceed southwest for 40 feet to connect to the western storage tank, while the other branch of the unloading line would continue an additional 440 feet to the eastern storage tank. The 6-inch-diameter cool-down line would recirculate LNG from the send-out pumps to the unloading arms and back to the process area. This system would keep the transfer pipelines cold during periods when an LNG carrier is not being unloaded.

An LNG sampling package would be installed on the unloading line to allow for sampling and analysis of the composition of the LNG. The transfer line coming off the wharf would also be equipped with emergency isolation valves.

2.1.3.3 Vapor Handling System

The pressure in the LNG carrier during unloading would be maintained through a system that allows vapor to flow back from the storage tanks to the carrier. A desuperheater would be installed on the wharf to control the temperature of the vapor returned to the ship to about -220 °F by injecting LNG into the vapor via the wharf transfer line. A vapor return KO drum would also be located on the wharf, to prevent liquid slugs downstream of the desuperheater and act as a drain pot for the unloading arms. Once unloading activities are completed, but before recirculation, LNG would be drained from the unloading arms to the vapor return KO drum and back to the LNG carrier by pressuring with gaseous nitrogen. After the LNG carrier has disconnected, the vapor return KO drum would be drained into the unloading line.

Ambient heat input into the LNG storage tanks would result in vaporization of LNG, allowing the tank to remain at a constant temperature. The resultant vapor, referred to as BOG, is removed by the vapor handling system to maintain the tank pressure. During unloading operations, BOG would be displaced by LNG entering the tanks and would need to be removed.

The BOG vapor handling system would consist of pipework, compressors, and a condenser. A vapor return line would convey vapor displaced from the storage tanks back to the LNG carrier. A pressure control valve on the line would maintain the required pressure at the vapor return arm.

The terminal design includes two 50-percent reciprocating BOG compressors. The BOG compressors are sized for a maximum capacity of 7.68 MMcfd. The compressors would operate in a duty/standby arrangement. The purpose of the BOG compressors is to raise the BOG pressure to a level at which the BOG could be condensed by the BOG condenser. The BOG compressors would also serve to control storage tank pressure during LNG carrier off-loading and during periods of low sendout. A desuperheater would be installed on the BOG compressor suction line to ensure that temperatures are kept below -250 °F. A KO drum would be provided on the BOG compressor suction to separate any injected liquid that is not vaporized in the compressor suction flow.

The BOG condenser would serve two functions: it would condense BOG into LNG and it would provide buffer capacity to the sendout pumps. The upper section of the condenser would include pressure control valves that would allow excess pressure to be vented or “padding gas” to return from the sendout line. The lower portion would produce buffer liquid for the send-out pumps, sized for a send-out rate of 1,500 MMcfd. Under normal operating conditions most of the LNG would by-pass the BOG condenser, but when sendout is at a minimum almost all the LNG would be routed through the top of the BOG condenser.

The terminal would contain one ignitable vent stack. The BOG header would be protected by a pressure controller, which would allow relief to the process vent, if required. Under normal operations, only inert purge gas (nitrogen) would be vented. The vent is designed for a maximum rate of 68,670 pounds per hour.

2.1.3.4 LNG Storage Tanks

LNG unloaded from the ships would be stored in two 160,000-m³ (1,006,000 barrel) full-containment storage tanks at a temperature of -260 °F and maximum internal pressure of 4.2 pounds per square inch gauge (psig). These would be on-ground type tanks, built on a reinforced concrete slab supported on a piled foundation, with base heating systems to prevent frost heave. Each storage tank would have a 9 percent nickel-steel inner container and a secondary pre-stressed concrete outer container, a reinforced concrete domed roof, a reinforced concrete outer container bottom, and an aluminum insulated support deck suspended from the outer container roof over the inner container. Each storage tank would be designed so that both the primary and secondary containers could both independently contain LNG. The diameter of the outer containers would be approximately 259 feet and the height to the top of the storage tank domes would be approximately 170 feet. Figure 2.1.3-5 shows the conceptual design of NorthernStar’s proposed storage tanks.

The load-bearing insulation beneath the inner container would consist of cellular glass. The space between the inner container and the outer container would be filled with expanded perlite insulation compacted to reduce long-term settling. The outer concrete container would be lined on the inside with carbon steel plates, as a barrier to moisture migration from the atmosphere reaching the insulation inside the outer container. This liner would also prevent vapor from escaping from inside the tank during normal operations. The storage tanks would meet the requirements of National Fire Protection Association (NFPA) 59A and 49 CFR 193. The inner container would be designed and constructed according to the requirements of API Standard 620. There would be no penetrations through the sidewalls or bottoms of the storage tanks. All piping into and out of the tanks would be from the top. There would be two fill lines on the roof of each tank.

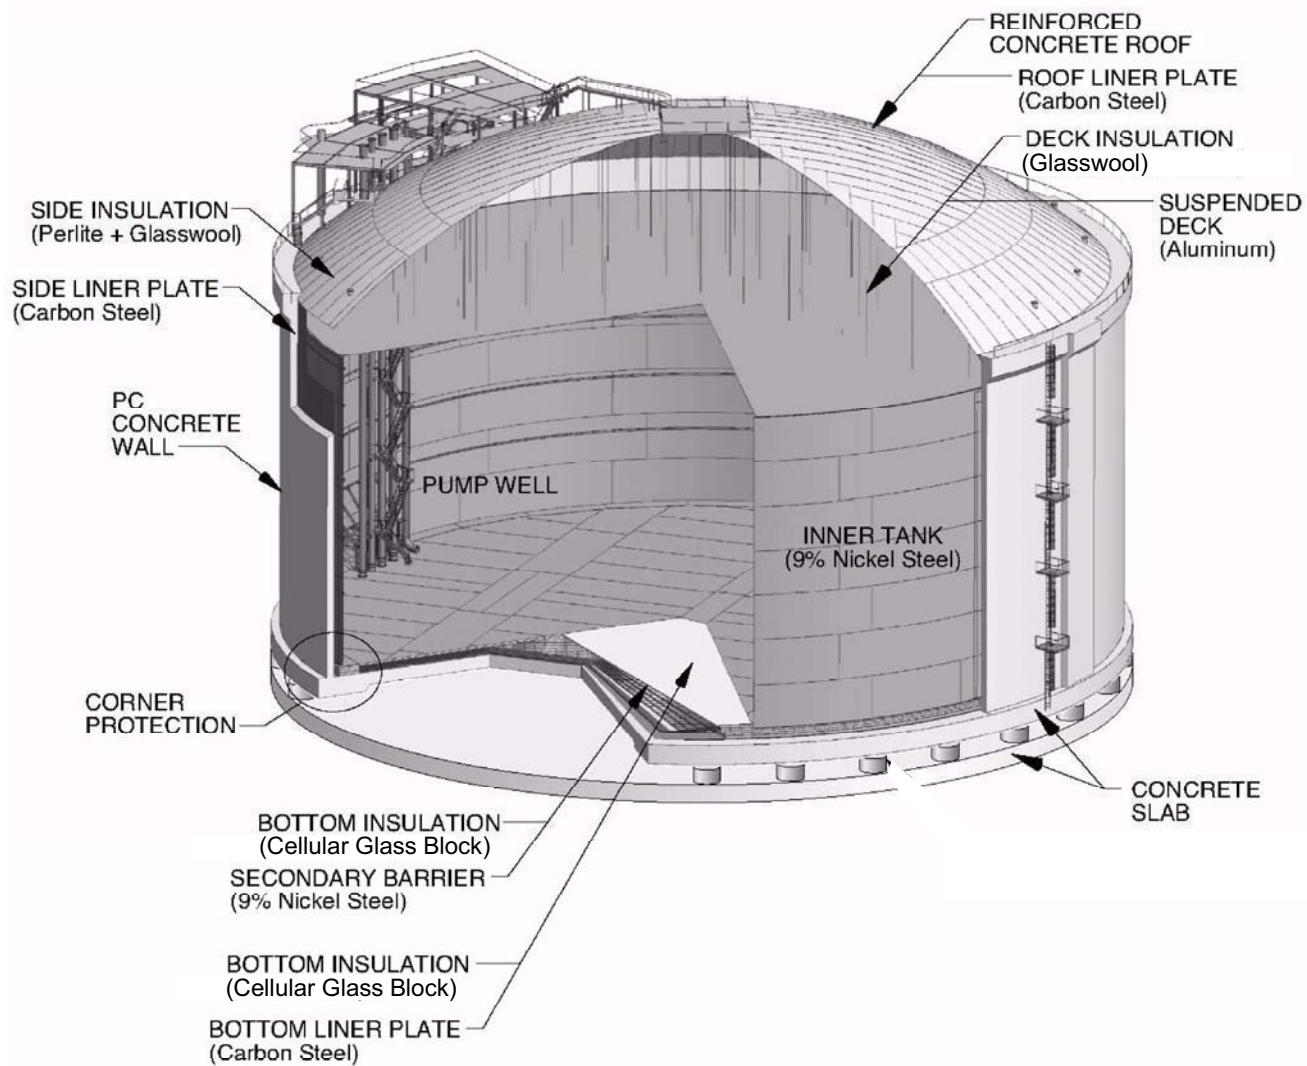

Figure 2.1.3-5
Bradwood Landing Project
 Conceptual Design of LNG Storage Tanks

Each storage tank would be equipped with three vertical submerged in-tank LNG pumps (six total). The in-tank LNG pumps would each have a capacity of 2,353 gpm at 145 psig. At the normal sendout rate, four pumps (two pumps per tank) would operate (leaving one spare pump for backup in each tank). The in-tank pumps would move LNG through the BOG condenser or the bypass and on to the sendout pumps.

2.1.3.5 Vaporization System

The five sendout pumps would take their feed from the BOG condenser outlet or the bypass line. During normal discharge, four sendout pumps would operate (with one as a back-up spare), each with a capacity of 2,398 gpm. The sendout pumps would discharge LNG to the vaporizers at a pressure of 1,320 psig.

The terminal would have seven SCVs, arranged in parallel, to re-gasify the LNG. Only six of the SCVs would operate under the nominal sendout rate of 1.0 Bcfd. With all seven SCVs in operation, the facility would have a peak sendout capacity of 1.3 Bcfd.

Within the SCVs, the LNG would pass through a warm water bath in high-pressure tubing, and be converted to a gaseous state. NorthernStar would use its on-site well to provide up to 0.2 million gallons of water for the initial filling of the SCVs. Produced water from the first SCVs filled would be used as much as practical to fill subsequent SCVs. Sendout gas would be burned to heat the water in the SCVs. The SCVs would operate at a pressure of about 1,291 psig. The natural gas produced would be at about 40 °F at sendout from the SCVs.

During normal operations, the SCVs would generate about 160 gpm of condensate water at a 1.3 Bcfd sendout rate. Excess water produced by the SCVs would pass to an overflow effluent pit where the hydrogen ion concentration (pH) of the water would be neutralized with alkaline chemicals. From the effluent pit, the SCV overflow water would be discharged into the Columbia River via a diffusion pipe.

2.1.3.6 Support Facilities

Buildings

The LNG terminal would include the following on-site service buildings:

- administration/warehouse;
- control;
- instrument air package shelter;
- switchrooms;
- power factor correction room;
- compressor building;
- wharf control/switch room;
- gatehouse/security building; and
- firewater pumphouse.

Pipe Racks

Pipe racks supporting LNG piping would be of reinforced concrete construction. Piping would be of welded steel.

Fuel Gas System

A system would be installed to supply and distribute natural gas as required to the fuel burning equipment at the LNG terminal. The primary source of natural gas for the fuel system would be recompressed BOG recovered from the LNG storage tanks. The fuel system would operate at a nominal pressure of 35 psig and would supply natural gas to be burned to warm the water bath within the SCVs. Natural gas used for space heating would be odorized with a small on-site odorization unit.

Nitrogen System

Nitrogen would be used during terminal start-up to purge the LNG storage tanks, process equipment, and piping. A nitrogen system would be installed at the LNG terminal to service the unloading arms and vapor return system.

Electrical System

The electricity for the LNG terminal would be supplied from the external grid of the local utility company (see section 2.2.1). A 1.5-mile-long 115-kV overhead electric line would connect the terminal to the existing Bonneville Power Administration (BPA) system. A new electric switch yard and substation would need to be built within the Bradwood Landing LNG terminal site. NorthernStar would also install an 800 kW diesel-powered standby generator to provide backup power for critical loads. This generator would provide service to instrumentation, air compressors, and plant lighting. The generator would be started using an electrical starter powered by a battery. In addition, there would be dual redundant uninterruptible power supplies (UPS) using static batteries and backup batteries located in separate specially designed battery rooms throughout the terminal in case of a power outage. UPS systems would be put into the plant control room and on the wharf. Electrical equipment would comply with the appropriate electrical area classifications as defined in NFPA 59A *Standards for the Production, Storage, and Handling of LNG* (NFPA 59A). A plant grounding system would be installed according to applicable industry standards, such as the Institute of Electrical and Electronics Engineers Standard 142.

Lighting

Exterior lighting would be provided at the terminal using high-pressure sodium type bulbs. Lighting fixtures would be installed on building exteriors, at the wharf, on the tank stairways and roof platforms, in the process area, and along the access roadway.

Water System and Wastewater Management

Non-potable water for construction and operational activities would be obtained from an on-site water well (see figure 2.1.3-2). During the 3-year construction period, NorthernStar estimates that a total of about 12.3 million gallons of groundwater from that well would be used for concrete making, initial testing of SCVs, hydrostatic testing of piping, equipment/vehicle washing, and personal/sanitary use. During operation of the LNG terminal, about 1.1 million gallons of groundwater would be used annually for landscape irrigation and personal/sanitary use. Bottled, potable water would be delivered to the terminal for operational staff use. Section 4.3.1 discusses the use of groundwater and potential project-related groundwater impacts.

Because most of the LNG terminal site would remain unpaved, stormwater would either directly infiltrate into the ground or would be collected in shallow infiltration ditches and routed to unlined settling ponds for infiltration into the ground. The stormwater retention ponds would be large enough to hold the volume of runoff generated from a 100-year storm. Stormwater within the tertiary earthen berm

surrounding the LNG storage tanks would be collected via swales and open channels and directed to spill impoundment basins. Water collected in the spill impoundment basins would be pumped into the on-site stormwater retention ponds. Stormwater management is discussed in further detail in sections 4.3.1 and 4.3.2. Sanitary wastewater from the LNG terminal would be treated and disposed of using an underground, on-site septic tank and drainfield, or other permitted treatment system if final site conditions are not suitable for a drainfield.

During construction of the terminal, about 75 million gallons of water from the Columbia River would be used for hydrostatic testing and ground improvements. During operation of the terminal, the fire suppression system would be tested weekly, and use about 4,400 gpm of water for about 1 hour for each test. Surface water use at the terminal and potential impacts are discussed in section 4.3.2.3.

All intakes at the proposed LNG terminal that withdraw water from the Columbia River would be screened in accordance with the NMFS and ODFW requirements. Intakes for hydrostatic test water may be temporary pump locations, which would be screened to comply with intake velocity and mesh requirements. Permanent intakes, such as fire suppression water, would be fitted with custom-sized screens to avoid entrainment or impingement of larval and juvenile fish. The screens would be cylindrical, with one closed end pointed upstream and the screens on the side of the cylinder. The screens would be kept free of debris by periodic backflushing with compressed air. Water intake locations are shown on figure 2.1.3-3.

Water used for hydrostatic testing and testing of the fire suppression system would be returned to the Columbia River. Condensate from the vaporizers would be discharged to the Columbia River from a subsurface outfall/diffuser mounted on the dock at a maximum rate of 160 gpm. Water discharge locations at the terminal are shown on figure 2.1.3-3.

Natural Gas Sendout Facilities

As described further in section 2.1.4, the LNG terminal would have facilities associated with the natural gas sendout pipeline, including a meter station, MLV, and pig launcher.

Safety and Security Systems

The proposed LNG terminal would include a fire detection and protection system, including automated detection of an LNG leak or spill, and LNG or non-process fires, fire suppression water, fire control equipment, fire proofing, and means of de-pressurizing an LNG carrier at dock. The fire protection system would include a firewater main capable of serving hydrants, the wharf spray curtain, and individual spray equipment; high expansion foam available at the spill impoundment basins; automatic dry chemical extinguishers at the relief valve discharge piping; and portable fire extinguishers located throughout the terminal.

The terminal is located within a 411-acre parcel to be acquired by NorthernStar. The terminal would be surrounded by a security fence, with appropriate lighting. Access into and out of the facility would be controlled through a gatehouse, and limited again at the wharf.

Construction Worker Parking, Access Roads, and Hunt Creek Bridge

NorthernStar would provide a parking lot for construction workers southeast of the Taylorville interchange at Highway 30, and proposes to bus workers into the LNG terminal. Access for workers and construction equipment from Highway 30 would be by way of existing county-maintained paved two-lane Clifton Road, for 2.4 miles to Bradwood Road. Clifton Road would be widened to a total of 28 feet with

shoulders, resulting in two 12-foot paved travel lanes with 2-foot gravel shoulders on each side of the road. An east-bound turning lane and a west-bound deceleration lane would be installed on Highway 30 at the intersection of Clifton Road. See section 4.8.2.7 for a further discussion of transportation and traffic to the LNG terminal.

An existing 1,150-foot-long, privately-owned gravel access road (Bradwood Road) enters the LNG terminal site from Clifton Road over a bridge that crosses Hunt Creek. Bradwood Road would need to be paved and widened for use during construction and operation of the proposed project. Similarly, the existing bridge over Hunt Creek is not adequate to withstand the anticipated vehicle loads associated with construction-related traffic and would be replaced with a 24-foot-wide bridge.

Railroad Relocation

There are existing train tracks within the proposed Bradwood Landing LNG terminal parcel. These tracks are operated by Portland & Western Railroad, Inc. (PWRR), on a right-of-way owned by the Oregon Department of Transportation (ODOT). No regularly scheduled trains currently run along the portion of this railroad through the Bradwood Landing terminal site. NorthernStar proposes to remove about a 4,200-foot-long section of the railroad through its parcel and relocate it up to 250 feet south of the present location of the tracks, and has entered into an agreement with PWRR and ODOT for this action.

2.1.4 Pipeline and Associated Aboveground Facilities

The Bradwood Landing Project would include construction and operation of an underground welded steel natural gas sendout pipeline and associated aboveground facilities. These facilities, including interconnects, meter stations, MLVs, and pig launchers and receivers, are shown on detailed maps contained in Appendix B.

2.1.4.1 Sendout Pipeline

A 36.3-mile-long sendout pipeline would extend from the LNG terminal at Bradwood, Oregon to an interconnection with Williams Northwest pipeline system north of Kelso, Washington. The pipeline would consist of about 18.9 miles of 36-inch-diameter pipe and 17.4 miles of 30-inch-diameter pipe (see table 2.1.4-1). The pipeline would be made of API SL-X-70 strength carbon steel, with a maximum allowable operating pressure of 1,280 psig. For the 36-inch-diameter pipe, the wall thickness would be 0.550-inch for Class 1 and 2 locations and 0.659-inch for Class 3 locations. For the 30-inch-diameter pipe, the wall thickness would be 0.458-inch for Class 1 and 2 locations and 0.550-inch for Class 3 locations. Section 4.11.9 explains these classifications in more detail.

TABLE 2.1.4-1				
Pipeline Facilities Associated with the Bradwood Landing Project				
Facility	Pipe Diameter (inches)	MP Range	Length (miles)	County, State
Natural Gas Sendout Pipeline	36	0.0 – 6.2	6.2	Clatsop, Oregon
		6.2 – 18.9	12.7	Columbia, Oregon
			18.9	
Subtotal			18.9	
	30	18.9 – 19.4	0.5	Columbia, Oregon
		19.4 – 36.3	16.9	Cowlitz, Washington
			17.4	
Subtotal			17.4	
Project Total			36.3	

The pipeline would originate at a pig launcher and meter station within the Bradwood Landing LNG terminal tract. The pipeline would exit the LNG terminal to the south, using horizontal directional drill (HDD) methods between mileposts (MP) 0.1 to 1.3 to pass under cliffs fronting the Columbia River, then proceed southwest of the Wauna Mill near MP 3.0, and easterly to the north of the community of Westport at about MP 6.0. The pipeline would cross through the alluvial plain lowlands adjacent to the southern shore of the Columbia River from Westport to Port Westward at about MP 18.0 in Columbia County, Oregon. HDD methods would be used to install the pipeline under the Columbia River from Port Westward, with the exit point on a hillside between the mouths of Mill Creek and Abernathy Creek at about MP 19.8 in Cowlitz County, Washington. From Bunker Hill, the pipeline would continue easterly, passing south of Eufaula Heights at about MP 26.0, generally following the route of the existing Kelso Beaver Pipeline (KB Pipeline) where practical. Realignment away from the KB pipeline route have been necessary where the KB pipeline was constructed in areas containing geological hazards such as poor slope stability, or to reduce waterbody crossing impacts. North of the community of Lexington, HDD methods would be used to cross under Highway 411 and the Cowlitz River at about MP 34.0. The pipeline would cross under the railroad and Interstate Highway 5 (using the HDD method), north of the community of Ostrander at about MP 35.5, and terminate at a new meter station to be constructed adjacent to the existing Williams Northwest pipeline system.

2.1.4.2 Aboveground Facilities

The aboveground facilities would consist of a sendout meter station, four interconnects with meter stations, six MLVs, two pig launchers, and two pig receivers. No compression is planned for the proposed pipeline because the pressure of the natural gas exiting the LNG terminal would be sufficient to overcome line losses and meet the interconnection and delivery point requirements. Table 2.1.4-2 lists the proposed aboveground facilities.

TABLE 2.1.4-2			
Aboveground Facilities Associated with the Pipeline for the Bradwood Landing Project			
Facility	Approximate MP	Associated and/or Collocated Facility	County, State
Meter Station			
Sendout Meter Station	0.0	LNG terminal, MLV, pig launcher	Clatsop, Oregon
Interconnects/Meter Stations			
Georgia-Pacific Wauna Mill Delivery Point	3.7	Not Applicable (NA)	Clatsop, Oregon
Northwest Natural Interconnect	11.4	NA	Columbia, Oregon
PGE Beaver Power Plant Delivery Point	18.9	NA	Columbia, Oregon
Williams Northwest Interconnect	36.3	MLV, pig receiver	Cowlitz, Washington
MLVs			
MLV #1	0.0	LNG terminal, pig launcher	Clatsop, Oregon
MLV #2	3.7	NA	Clatsop, Oregon
MLV #3	18.8	Pig receiver, pig launcher	Columbia, Oregon
MLV #4	26.3	NA	Cowlitz, Washington
MLV #5	31.7	NA	Cowlitz, Washington
MLV #6	36.3	Williams Northwest Interconnect, pig receiver	Cowlitz, Washington
Pig Launchers and Receivers			
Pig Launcher	0.0	LNG terminal, MLV	Clatsop, Oregon
Pig Receiver	18.8	Pig launcher, MLV	Columbia, Oregon
Pig Launcher	18.8	Pig receiver, MLV	Columbia, Oregon
Pig Receiver	36.3	Williams Northwest Interconnect, MLV	Cowlitz, Washington

Sendout Meter Station

A sendout meter station would be located at MP 0.0 within the LNG terminal. This facility would be used to meter and sample natural gas after it leaves the vaporizers and before it is sent to the sendout pipeline. The meter station would include two meter runs, consisting of a custody-transfer flow meter, a pressure regulator, isolation block valves, and associated instrumentation and controls. Similar to other interstate pipelines in the region, the natural gas would not be odorized before it is sent to the sendout pipeline.

Interconnects/Meter Stations

At MP 11.4, in Columbia County, Oregon, NorthernStar's pipeline would interconnect with Northwest Natural's existing bidirectional intrastate pipeline facilities capable of transporting gas to Northwest Natural's Mist underground natural gas storage facility. NorthernStar's pipeline would interconnect with Williams Northwest existing interstate pipeline facilities at the terminus of the pipeline at about MP 36.3, in Cowlitz County, Washington. NorthernStar also proposes to construct interconnects at two delivery points, at MP 3.7 (Wauna Mill) in Clatsop County, Oregon, and at MP 18.9 (PGE Beaver Power Plant) in Columbia County, Oregon.

Meter stations, consisting of a custody-transfer flow meter, a pressure regulator, isolation block valves, and all associated instrumentation and controls, would be installed at each interconnect and delivery point to measure the flow of natural gas from NorthernStar's pipeline to the downstream entity. Each interconnect and delivery point would consist of one or more meter runs located inside fenced and gated sites. Permanent entrance drives would be installed from existing roads to the proposed facilities.

Mainline Block Valves

Aboveground pipeline MLVs would be installed at MP 0.0 at the LNG terminal and at the terminus of the pipeline at MP 36.3 where it interconnects with the Williams Northwest facilities. An MLV would also be installed where the pipeline transitions from 36 inches in diameter to 30 inches in diameter at MP 18.8. Intermediate MLVs would be installed at MPs 3.7, 26.3, and 31.7. The MLVs would isolate pipeline segments from the rest of the system in order to contain unplanned pipeline system releases and to provide controlled venting during a planned pipeline system blow-down. The MLVs would be remotely operated and monitored. All MLVs would be installed in accordance with DOT safety requirements based on area population classifications.

Pig Launchers and Receivers

A pig launcher would be installed at MP 0.0 at the LNG terminal. A pig launcher and receiver would be installed where the pipeline transitions from 36 inches in diameter to 30 inches in diameter at MP 18.8. A pig receiver would be installed at the Williams Northwest interconnect at MP 36.3. These facilities would allow monitoring of the pipeline using internal inspection tools.

2.1.5 Wetland and Habitat Mitigation Sites

In order to compensate for temporary or permanent impacts on wetlands, wildlife habitats, and salmonid habitats that could not otherwise be mitigated, NorthernStar produced a *Preliminary Engineering Design Draft Mitigation Plan* (Compensatory Mitigation Plan), with the third version filed on August 3, 2007.² The compensatory mitigation sites were identified only after all other forms of impact mitigation (i.e., avoidance, minimization, rectification, and reduction) were considered and, when

² NorthernStar submitted its Mitigation Plan – 3rd Revision for the Bradwood Landing Terminal and Pipeline to the FERC on August 3, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, by selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

appropriate, implemented. The locations of the sites are illustrated on figure 2.1.5-1. NorthernStar proposes to restore habitat at the middle Svensen Island, Petersen Point, and Delameter Creek Mitigation Sites. In addition, NorthernStar would preserve habitat at the Hunt Creek Mitigation Site and would preserve and provide limited enhancement to the lower Svensen Island Mitigation Site. Wetland impacts and mitigation are discussed in section 4.4.1 and terrestrial habitat impacts and mitigation are discussed in sections 4.4.2 and 4.5.

Since the filing of its Compensatory Mitigation Plan, NorthernStar has received input from agencies and stakeholders through site visits in both Oregon and Washington and through comments on the draft EIS and other comment periods associated with permits required for the project. In addition, numerous discussions have taken place between the FERC staff, NMFS, FWS, and NorthernStar regarding the mitigation proposed by NorthernStar as it relates to the BA and EFH Assessment (see table 1.4-1). As a result of this additional input on its proposed mitigation, NorthernStar is revising its Compensatory Mitigation Plan. The revised Compensatory Mitigation Plan will be filed with the FERC upon completion and will be included in the FERC's revised BA and EFH Assessment. Because NorthernStar's Compensatory Mitigation Plan has not been finalized, **we recommend that:**

- **NorthernStar should continue to consult with the COE, NMFS, FWS, ODFW, ODSL, WDE, and other appropriate agencies to finalize its Compensatory Mitigation Plan. NorthernStar should file the final Compensatory Mitigation Plan along with agency comments and appropriate approvals with the Secretary prior to construction of the LNG terminal and pipeline facilities.**

2.2 NONJURISDICTIONAL FACILITIES AND INTERRELATED ACTIVITIES

In addition to the facilities discussed in section 2.1, the Bradwood Landing Project would require construction of facilities that do not fall under the Commission's jurisdiction. These include electric transmission facilities and three lateral pipelines. Although these facilities are not regulated by the FERC, they are related to the project and their potential environmental impacts are considered in this EIS.

Another action not directly regulated by the FERC is NorthernStar's proposed SEI. We consider the SEI to be an interrelated and interdependent action, and therefore it is discussed below.

2.2.1 Power Line

As previously mentioned, the electricity for the LNG terminal would be supplied from the external grid of the local utility company. A 1.5-mile-long 115 kV power line would be constructed on a 100-foot-wide right-of-way to bring 25 megawatts (MW) of power to operate the LNG terminal (see figure 2.2.1-1). The power line would interconnect with the existing (BPA) system and would be constructed, owned, operated, and maintained by PacifiCorp. Five new standard H-frame pole towers would be constructed and one existing BPA tower would be rebuilt to support the 1.5-mile-long power line. The 60- to 105-foot-tall towers would be secured about 11 feet into the ground, resulting in a total aboveground height of approximately 50 to 95 feet. The power line would terminate at a substation located within the LNG terminal site. A 115 kV metering station would also be constructed near the LNG terminal substation on the project site. Necessary communication and redundant backup equipment would be placed in a National Electrical Manufacturers Association-rated outdoor cabinet attached to the structure. Existing roads could be used to access the 100-foot-wide construction right-of-way for the power line, but approximately 465 feet of additional access would be required for construction and maintenance of the H-frame pole towers. Some limited improvements to the existing access roads, such as widening and surfacing with aggregate, may be necessary to allow passage of construction and maintenance vehicles. NorthernStar proposes to use crushed rock aggregate supplied only from approved permitted upland sources. An analysis of the environmental impacts associated with construction and operation of the power line is provided in section 4 of this EIS.

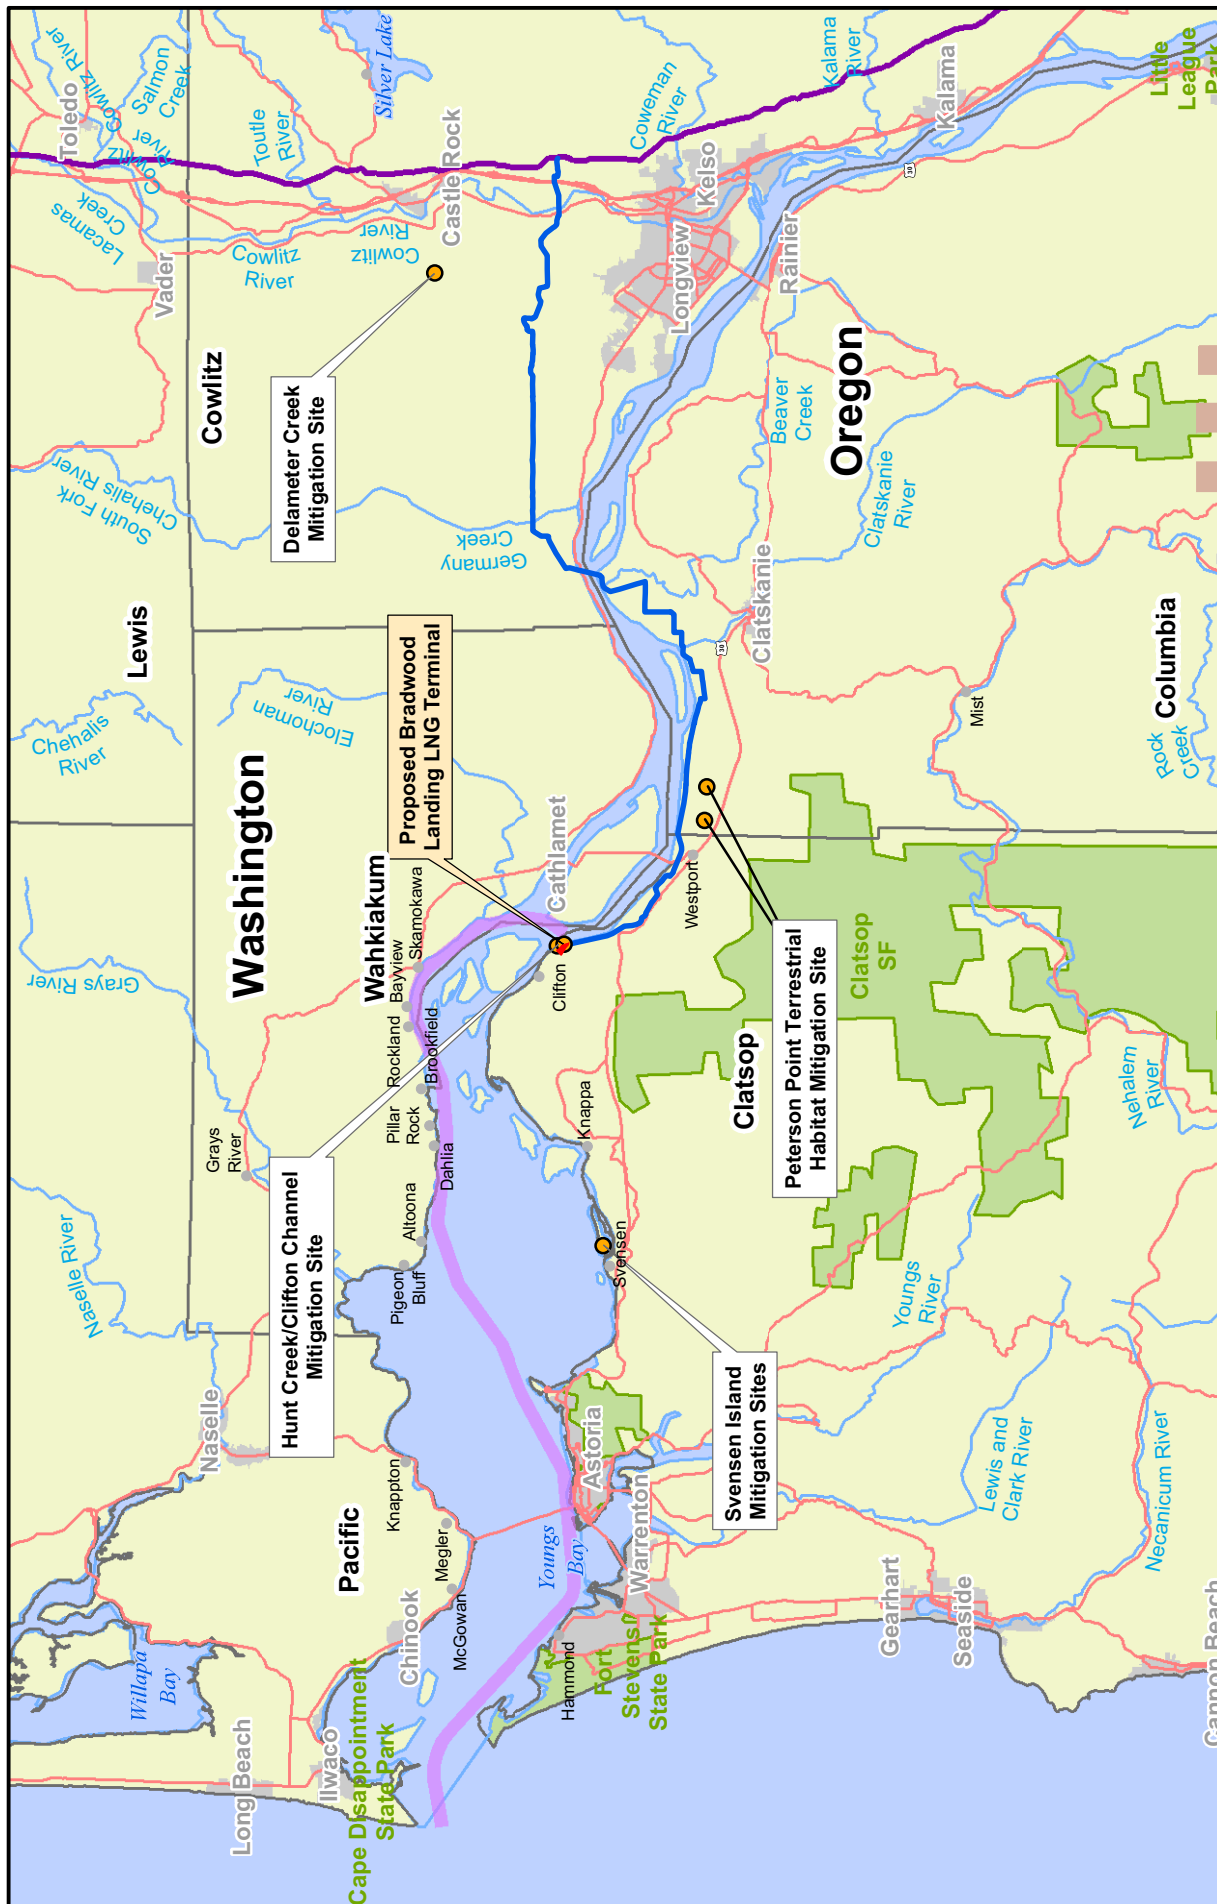

Figure 2.1.5-1
Bradwood Landing Project
 Mitigation Site Locations

2.2.2 Pipeline Laterals

NorthernStar has identified three potential lateral pipelines that would be constructed in association with the proposed project. These facilities would be constructed by entities other than NorthernStar and are tentative at this time. Preliminary, conceptual information on these three laterals is provided below.

As previously discussed, NorthernStar proposes to construct metering facilities associated with the interconnect/delivery point at MP 3.7 for the Wauna Mill. Georgia-Pacific would obtain the necessary permits and construct the lateral pipeline necessary to connect the metering facilities at the delivery point to the tie-in with its existing natural gas supply system. It is anticipated that the lateral would be 4 inches in diameter and about 0.2 mile long.

Northwest Natural would construct a lateral pipeline from the proposed interconnect with NorthernStar's pipeline at MP 11.4 to its existing pipeline. The lateral would be about 1.4 miles long and 24 inches in diameter. Northwest Natural would obtain the necessary permits to construct and operate its lateral pipeline.

At MP 18.9, NorthernStar would construct metering facilities associated with the interconnect/delivery point for the PGE Beaver Power Plant. An approximately 0.6-mile-long, 12-inch-diameter lateral pipeline would be constructed by PGE from the interconnect/delivery point to its existing natural gas supply system. The lateral pipeline would be constructed entirely within PGE property. PGE would obtain the necessary permits to construct and operate its lateral pipeline.

Based on our review of the information provided by NorthernStar on these potential lateral pipelines, it is likely that environmental impacts associated with these nonjurisdictional facilities would be minimal. However, to ensure that potential issues are adequately addressed, **we recommend that:**

- **Prior to pipeline construction, NorthernStar should file with the Commission the following information on the nonjurisdictional lateral pipeline facilities:**
 - a. **final routing and design information, including maps depicting the location of the facilities;**
 - b. **documentation of consultations with the appropriate agencies and the status of federal, state, or local permits or approvals required for their construction; and**
 - c. **status and copies of agency clearances (or copies of any surveys and reports prepared) for wetlands, threatened and endangered species, and cultural resources.**

2.2.3 Salmon Enhancement Initiative

NorthernStar proposes to implement an SEI to contribute to the recovery of salmon and the lower Columbia River ecosystem. NorthernStar proposed the SEI as a voluntary action that would be above and beyond the mitigation measures used to avoid, minimize, rectify, reduce, and/or compensate for environmental impacts that are required by the regulations. However, various permit requirements would ensure its implementation if the project is authorized. NorthernStar's SEI would entail providing funding for habitat preservation, enhancement, and restoration projects on the lower Columbia River that would total approximately \$59 million over the life of the Bradwood Landing Project. The National Fish and

Wildlife Foundation's Western Partnership Office in Portland, Oregon would serve as the fiscal agent for SEI funds. The long-term implementation of the SEI is outside of the FERC's regulatory authority. Potential impacts on federally listed species due to the SEI are described in section 4.6.2.2 and will be included in the revised BA and EFH Assessment.

2.3 LAND REQUIREMENTS

Table 2.3-1 summarizes the land requirements for the facilities associated with the Bradwood Landing Project.

TABLE 2.3-1		
Summary of Land Requirements Associated with Construction and Operation of the Bradwood Landing Project		
Facility	Land Affected During Construction (acres)	Land Affected During Operation (acres)
LNG Terminal		
Offshore Maneuvering Area	58.0	58.0
Marine Berth	5.5	1.0
Onshore LNG Terminal Facilities		
Onshore Portion of Wharf head	1.0	0.8
Transfer Pipelines	3.5	3.5
LNG Storage Tank Area	15.5	14.5
Vaporizers and Process Area	6.2	6.2
Meter Station	0.2	0.2
Buildings	1.0	0.5
Water Storage and Treatment Areas	5.5	4.5
Access Road	0.6	0.6
Railroad Relocation	9.4	0.0
Buffer	6.0	1.0
Other	13.0	7.3
Construction Worker Parking Lot	5.0	0.0
Power Line ^a	16.9	16.9
LNG Terminal Subtotal	148.2	115.9
Pipeline		
Pipeline Right-of-Way ^b	475.8	232.8
Temporary Extra Workspace	54.0	0.0
Pipe Storage and Contractor Yards	18.4	0.0
Aboveground Facilities	4.8	1.2
Access Roads	0.0	0.0
Pipeline Subtotal	553.0	234.0
Project Total	701.2	349.9
^a Based on a 100-foot-wide right-of-way for both construction and operation of the power line and a 100-foot-wide construction area for access roads.		
^b Based on an 85- to 120-foot-wide construction right-of-way for the main pipeline, and a 100-foot-wide construction right-of-way for the interconnects. Permanent rights-of-way would be 50 feet wide.		

2.3.1 Waterway for LNG Carrier Transit and Turning Basin

As previously mentioned above, LNG carriers heading to the Bradwood Landing LNG terminal would transit some 38 miles up the Columbia River from its mouth within an existing navigation channel. The states of Washington and Oregon share jurisdiction and ownership of the river and its bottom. The

navigation channel is maintained by the COE. The navigation channel was dredged to a depth of 40 feet by the COE in 1976, and in 2006 the COE began to deepen the channel to 43 feet under a project it authorized in 2004. For most of its length from the mouth of the Columbia River to Bradwood at CRM 38 the federal navigation channel is 600 feet wide. NorthernStar is not proposing to make any modifications to the navigation channel in the Columbia River. However, NorthernStar is proposing to construct a turning basin/maneuvering area adjacent to the existing navigation channel. This maneuvering area would be about 2,000 feet by 2,000 feet in size and cover about 58 surface acres in the Columbia River. To create the maneuvering area, NorthernStar would have to dredge about 46 of the 58 acres and remove approximately 700,000 cubic yards of sediment from the river bottom.

2.3.2 LNG Terminal Facilities

The terrestrial portion of the LNG terminal would be located within a 411-acre parcel that NorthernStar currently controls on the southern shore of the Columbia River and adjacent to the southeastern end of the Clifton Channel in Clatsop County, Oregon. This place, called Bradwood Landing, was formerly the site of a series of historic timber mills that operated between about 1843-1852, 1910-1920, and 1930-1962. The mill and town at Bradwood was abandoned, and structures were destroyed or removed by the early 1980s. Wooden pilings along the river's edge associated with the former Bradwood saw mill, as well as a former mill pond, are still present. Between 1966 and 2002, the COE used the site for placement of about 873,000 cubic yards of dredged material from maintenance of the Columbia River navigation channel.

The marine berth at the LNG terminal would occupy about 1 acre within the Columbia River, including the unloading platform and mooring dolphins. The operational size of the terrestrial portion of the LNG terminal would be about 40 acres. Another 17.8 acres would be used for the power line right-of-way (see section 2.2.1). A layout of the proposed facilities is provided on figure 2.1.3-1. Figure 2.3.2-1 depicts the LNG terminal construction area. Additional information on the land use and requirements for the LNG terminal site is provided in section 4.7.2.1.

2.3.3 Pipeline and Associated Aboveground Facilities

NorthernStar's proposed sendout pipeline would be installed within a region dominated by forest, with secondary uses that include cropland, pasture, and rangeland (section 4.7 provides more details about land use). About 19.4 miles of the pipeline would be within the State of Oregon (Clatsop and Columbia Counties) and about 16.9 miles of the pipeline would be within the State of Washington (Cowlitz County).

Construction of the pipeline facilities would disturb a total of about 553.0 acres of land, including the pipeline construction right-of-way, temporary extra workspace, two pipe storage and contractor yards, aboveground facilities, and access roads. Of this total, 475.8 acres would be disturbed by the pipeline construction right-of-way, 54.0 acres would be disturbed by temporary extra workspace, 18.4 acres would be disturbed by two pipe storage and contractor yards, and 4.8 acres would be disturbed by aboveground facilities. Modifications or improvements to existing roads used to access the project would not be required.

Approximately 234.0 acres of the 553.0 acres used for construction would be required for operation of the project. Of this total, 232.8 acres would be for the pipeline permanent right-of-way and 1.2 acres would be for the aboveground facilities. The remaining 319.0 acres would be allowed to revert to its former use. Additional information on the land use and requirements for the pipeline facilities is provided in section 4.7.3.1.

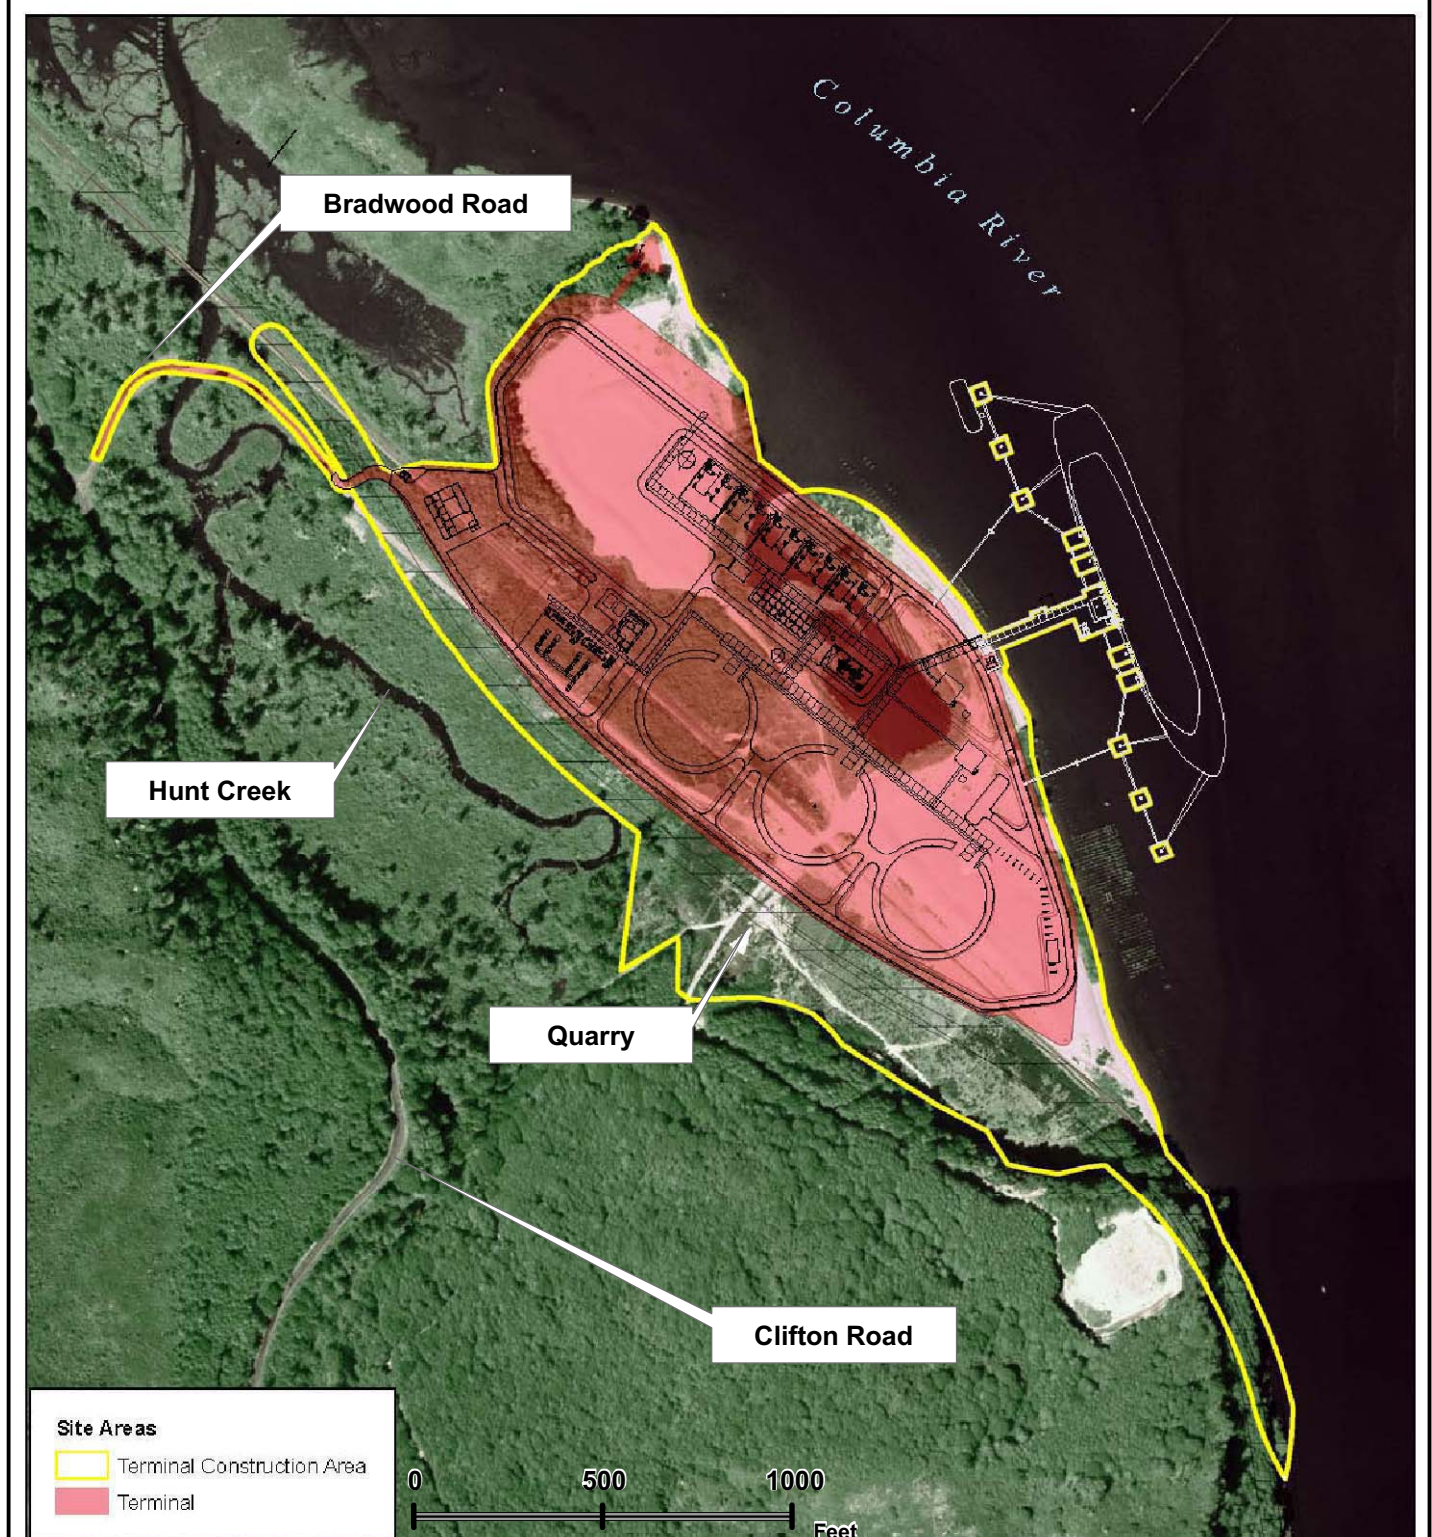

Figure 2.3.2-1
Bradwood Landing Project
Proposed LNG Terminal Construction Area

About 8.0 miles (22 percent) of the 36.3-mile-long pipeline route would be constructed adjacent to the existing KB pipeline. The remaining 28.3 miles (78 percent) would be constructed on newly created right-of-way.

NorthernStar proposes to use a 100-foot-wide construction right-of-way for the majority of the pipeline route. NorthernStar has also indicated that an additional 20 feet of construction right-of-way width may be needed for stockpiling topsoil wherever topsoil must be segregated from subsoil (e.g., in agricultural and residential lands). The 20 feet of additional width is based on the segregation of up to a 12-inch-thick layer of topsoil from directly over the pipe trench and under the spoil pile (trench plus spoil side).

Where the Bradwood Landing pipeline would be adjacent to the existing KB pipeline, the proposed temporary construction right-of-way would overlap onto the existing pipeline's permanent right-of-way. The overlap would be up to 10 feet on the spoil side of the pipe trench, but no closer than 15 feet from the existing pipeline. This would allow room to keep construction equipment off the operating pipeline, thus avoiding potentially damaging the existing pipeline.

In wetlands where the pipeline crossing would exceed 100 feet in length, NorthernStar proposes to use a 100-foot-wide construction right-of-way to account for the slumping of saturated segregated spoil piles. NorthernStar would reduce the construction right-of-way to a width of 85 feet in wetlands where the crossing length is 100 feet or less. The 85-foot limitation on the construction right-of-way width would not apply to wetlands in actively cultivated or rotated cropland. Based on the information provided by NorthernStar, the proposed 85-foot and 100-foot-wide right-of-way is necessary and justified to allow for safe and efficient construction of the pipeline in wetlands. Pipeline impacts on wetlands are further discussed in section 4.4.1.3.

Following construction, a 50-foot-wide permanent right-of-way would be retained for operation and maintenance of the pipeline. The typical right-of-way cross sections that NorthernStar would use for the pipeline route are provided in Appendix D.

In addition to the construction right-of-way, NorthernStar would require temporary extra workspace outside the standard construction right-of-way at locations where additional excavation, soil placement requirements, or equipment management and staging would make it impracticable to carry out all construction operations within a 100-foot-wide corridor. These would include feature (e.g., road, railroad, waterbody) crossings; areas with steep side slopes or severe terrain; areas requiring topsoil segregation; tie-ins to existing pipelines and laterals; HDD entry and exit points; and staging and fabrication areas for HDD pull sections. NorthernStar has identified 43 temporary extra workspaces areas that are required for the project, affecting approximately 54.0 acres.

To support construction of the pipeline, NorthernStar proposes to use two pipe storage and contractor yards, one in Oregon (Yard A) and one in Washington (Yard B). Yard A would be located adjacent to the proposed pipeline at approximate MP 4.4, on land owned by Georgia Pacific and used previously for dredged material disposal (DMD) (see figure 2.3.3-1). Yard B would be located in Longview on current commercial property (see figure 2.3.3-2). Combined, the yards would affect 18.4 acres of previously disturbed land.

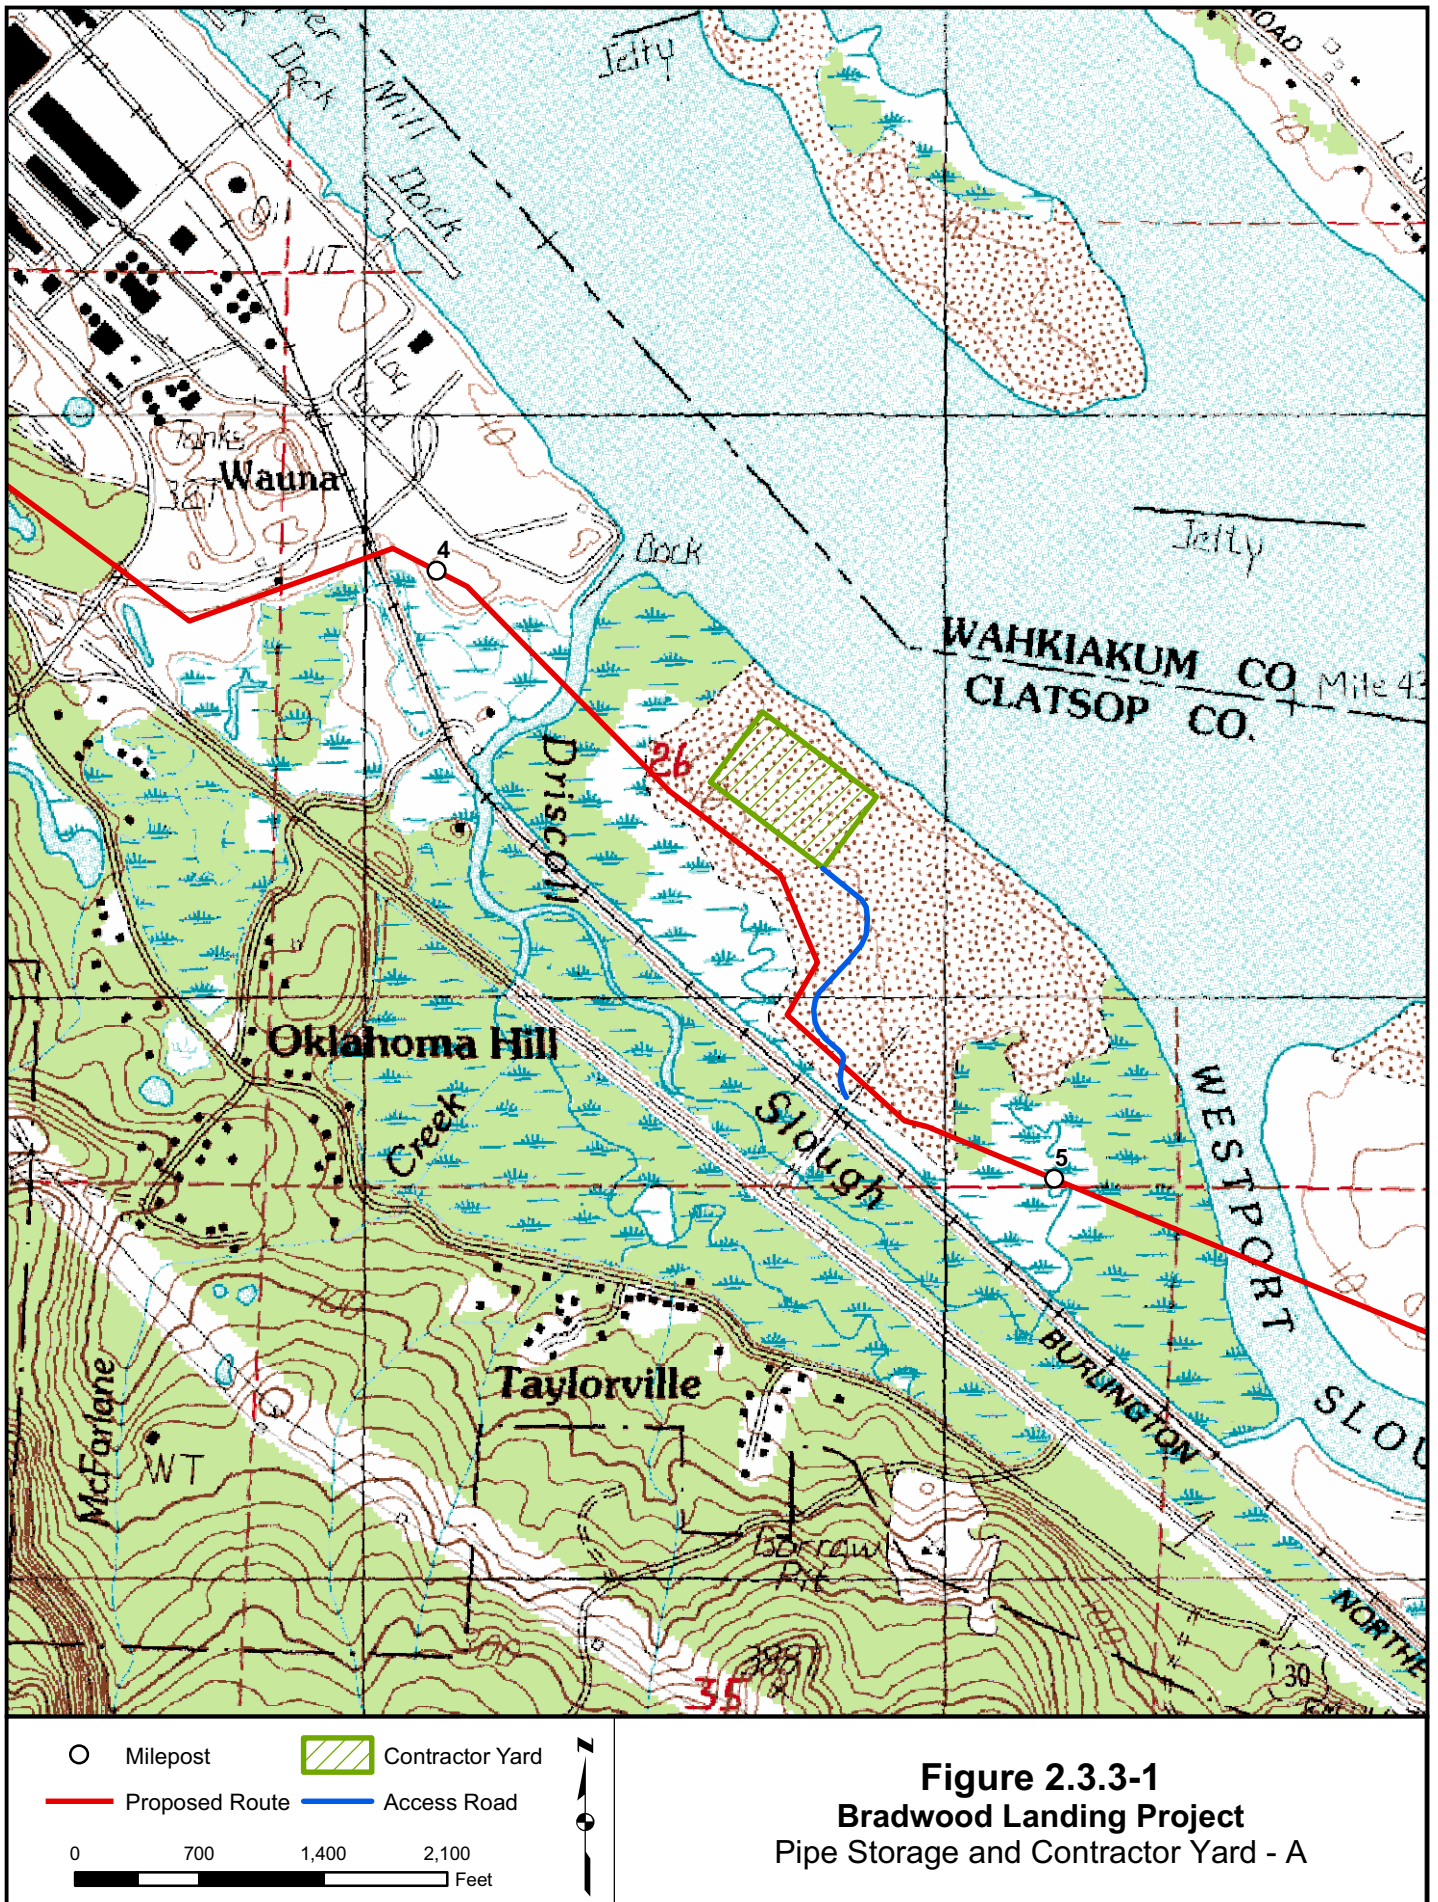

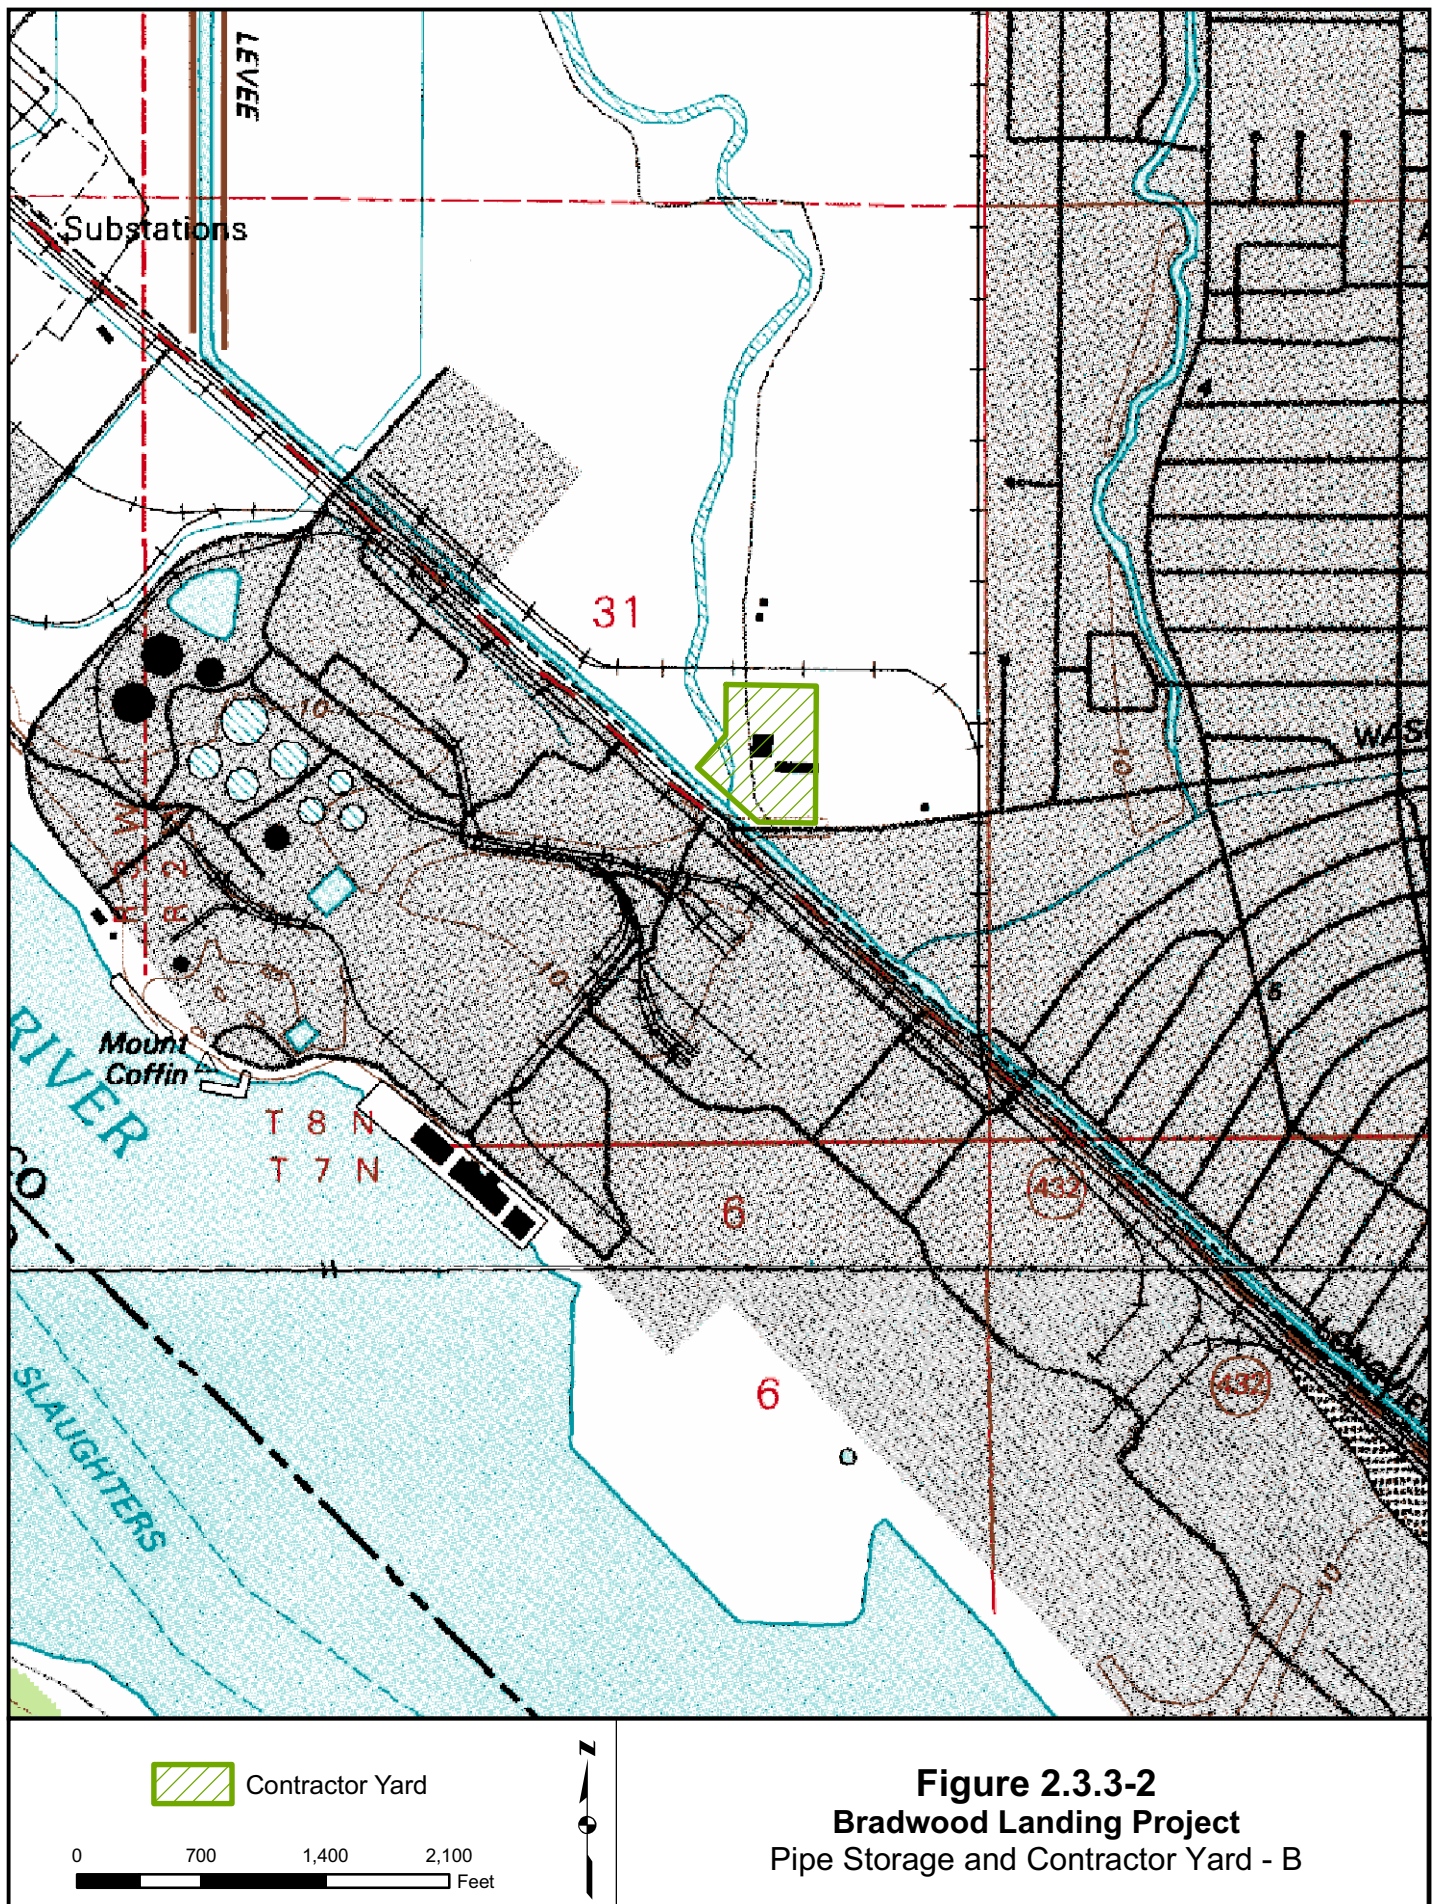

Figure 2.3.3-1
Bradwood Landing Project
 Pipe Storage and Contractor Yard - A

NorthernStar proposes to construct: 1) one pig launcher within the LNG terminal at MP 0.0, one pig launcher/receiver at MP 18.8, and one pig receiver at the pipeline terminus at MP 36.3; 2) meter stations at each of the following locations: the LNG terminal (MP 0.0), the delivery point to the Wauna Mill (MP 3.7), the interconnection with the Northwest Natural intrastate pipeline to the Mist storage facility (MP 11.4), the delivery point to the PGE Beaver Power Plant at Port Westward (MP 18.9), and the terminus of the pipeline at the interconnection with the Williams Northwest pipeline (MP 36.3); and 3) four MLVs at MPs 3.7, 18.8, 26.3, and 31.7. For each of these facilities, about 4.8 and 1.2 acres would be required for construction and operation, respectively.

NorthernStar would access the construction right-of-way via 32 existing public and private roads that intersect the right-of-way. The majority of roads are classified as dirt roads.

2.4 CONSTRUCTION PROCEDURES

This section describes the general procedures proposed by NorthernStar for construction of the LNG terminal and pipeline facilities. Refer to section 4.0 for more detailed discussions of proposed construction and restoration procedures as well as additional measures that we are recommending to mitigate environmental impacts.

The proposed LNG terminal and natural gas pipeline would be designed, constructed, operated, and maintained in accordance with federal safety standards that are intended to ensure adequate protection for the public and to prevent LNG and natural gas pipeline accidents or failures.

Under the provisions of the Natural Gas Pipeline Safety Act of 1968, as amended, NorthernStar would design, construct, operate, and maintain the LNG terminal facilities in accordance with the DOT's *Liquefied Natural Gas Facilities: Federal Safety Standards* (49 CFR 193). The facilities would also be required to meet NFPA 59A. These standards specify siting, design, construction, equipment, and fire protection requirements for new LNG facilities. The ship unloading facilities and any appurtenances located between the LNG carriers and the last valve immediately before the LNG storage tank would be required to comply with applicable sections of the Coast Guard regulations in *Waterfront Facilities Handling Liquefied Natural Gas* (33 CFR 127) and Executive Order 10173.

The proposed pipeline facilities would be designed, constructed, operated, and maintained in accordance with DOT regulations in *Transportation of Natural and Other Gas by Pipeline: Minimum Federal Safety Standards* (49 CFR 192). Among other design standards, these regulations specify pipeline material selection; minimum design requirements; protection from internal, external, and atmospheric corrosion; and qualification procedures for welders and operations personnel. In addition, NorthernStar would comply with the siting and maintenance requirements in 18 CFR 380.15 and other applicable federal and state regulations.

2.4.1 LNG Terminal Facilities

NorthernStar would construct the terminal facilities in accordance with its *Erosion and Sediment Control Plan – Bradwood Landing Terminal* (terminal ESC Plan). The terminal ESC Plan was developed in accordance with the requirements necessary for submittal of the General 1200-C NPDES permit application issued by the ODEQ. The terminal ESC Plan includes Best Management Practices (BMP) as recommended by the ODEQ's 2005 *Erosion and Sediment Control Manual*. In addition to erosion and sediment control measures, this plan describes specifications for hazardous material transportation, handling, storage, spill prevention, and spill response. A final terminal ESC Plan would be completed following preparation of the specific phased construction plans.

NorthernStar would construct the pipeline facilities in accordance with the FERC staff's *Upland Erosion Control, Revegetation, and Maintenance Plan* (Plan) and *Wetland and Waterbody Construction and Mitigation Procedures* (Procedures), with FERC-approved alternative measures (see section 4.4.1.3). The intent of the FERC staff's Plan and Procedures is to assist applicants by identifying baseline mitigation measures for minimizing the extent and duration of disturbances on soils, wetlands, and waterbodies associated with projects under the FERC's jurisdiction throughout the country. As general guidelines, the Plan and Procedures may be less stringent than state and local guidelines that are based on state or local concerns, issues, and/or regulations. NorthernStar has also drafted an *Erosion and Sediment Control Plan for Oregon – Bradwood Landing Pipeline* (pipeline ESC Plan) and a *Construction Stormwater Pollution Prevention Plan for Washington – Bradwood Landing Pipeline* (SWPPP).³ These plans incorporate elements of the FERC's Plan and Procedures, state and county requirements and provisions, stormwater pollution prevention plans, and spill prevention and response procedures. Drafts of these plans were included in NorthernStar's JPA and JARPA. The pipeline ESC Plan and SWPPP are discussed further in section 4.2.3.2.

Construction of the LNG terminal facilities would include site preparation; construction of the ship berth and unloading facilities along the shoreline of the Columbia River; and construction of the LNG storage, process, and support facilities. Associated construction activities would include dredging of the ship berth and maneuvering area in the Columbia River.

Typical construction activities would occur between 7 AM and 7 PM, 5 days per week. During concentrated periods, construction may include longer hours and additional days of the week to complete a particular construction phase more efficiently. Pile driving may occur between the hours of 7 AM and 10 PM (for about 60 days spread over a period of up to 120 days) and dredging may occur 24 hours per day (for a period of approximately 48 to 72 days). These extended hours allow for the construction activities to be completed under a compressed schedule, reducing the number of total construction days for pile driving and dredging. This is a typical approach to construction because it limits the length of time people who live in the vicinity may be affected.

The LNG terminal components and equipment would be brought to the site by truck or rail. Depending on their sizes, various facility components would arrive in different states of assembly. Some equipment would be self-contained and require no assembly. On-site workshops, staging, and laydown areas would be equipped and sized appropriately to complete the final assembly. No major fabrication of facility components is anticipated on site.

A brief explanation of some of the primary construction tasks is provided below.

2.4.1.1 Site Preparation

Site work at the LNG terminal would begin with clearing and grubbing, followed by rough grading of the entire site to allow for safe passage of construction equipment and materials. Approximately 50,000 cubic yards of soil and vegetation would be relocated to an on-site area along the cliff. During grading, appropriate erosion control measures would be installed, including temporary drainage ditches, catchment ponds, and silt fences. Aggregate (crushed rock) needed for project construction, including road improvements, would be sourced from an existing permitted quarry, and may

³ NorthernStar included its terminal ESC Plan and pipeline ESC Plan as part of its JPA, and included its SWPPP as part of its JARPA. NorthernStar's JARPA was filed with the FERC on November 6, 2006, and supplemented with a filing on November 22, 2006. NorthernStar also filed its JPA on November 22, 2006, and filed revisions to the JPA with the FERC on April 5, 2007. These documents are available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range. The FERC's Plan and Procedures are also available to the public on the FERC's Internet web page by clicking on Industries, Gas, Environment, Guidelines.

include material from an existing permitted basalt quarry located within the proposed LNG terminal site. Concrete would be supplied by an on-site batch plant.

Existing dredge piles on the property would be distributed across the site to serve as the base for the LNG terminal. NorthernStar proposes to use up to 700,000 cubic yards of the material dredged from the ship maneuvering area in the Columbia River to raise the base for the terminal to the desired elevation of 20 to 25 feet North American Vertical Datum (NAVD) 88, with a perimeter berm at an elevation 5 feet higher. The proposed elevation for the LNG terminal was designed to be well above the 100-year floodplain, which is at 13.23 feet NAVD.

NorthernStar would pipe the dredged materials to the LNG terminal site using hydraulic cutterhead dredging equipment. Dredged material would be piped to the more distant areas of the site first. The water that conveys the dredged material would separate from the material as it is deposited on the site. NorthernStar expects that all or most of the dredge water would percolate into the sandy soil at the site. NorthernStar would construct a berm to prevent any dredge water from washing into adjacent wetlands, Hunt Creek, or the Columbia River. Any dredge water that does not percolate into the soil would drain to the low point within the berm, which would be the former lumber mill log pond, where it would accumulate. Any silt in the water would settle out in the pond. Additional details regarding the dredge water are provided in section 4.3.2.3.

The berm used to contain the dredged material would become the permanent 5-foot containment berm that surrounds the entire site. In most places, concrete would be mixed with the sand to strengthen the berm and minimize its footprint. A paved perimeter road would be constructed on top of the berm. Once the dredged material has been compacted and stabilized and geotechnical improvements have been made, the facilities would be constructed. Because many of the construction activities would overlap with each other, the site would be subdivided into work areas assigned to the contractor and major subcontractors.

The material that is dredged from the ship berth and maneuvering area that is not placed at the LNG terminal site would be placed at the Wahkiakum County Sand Pit site, located at the northern end of Puget Island. Wahkiakum County is currently seeking a permit to receive 205,000 cubic yards of material for beach protection at the Sand Pit site. Project dredge material would be placed at the Sand Pit site up to the maximum permitted amount available at the time of dredging. This placement area and other alternative dredged material placement sites considered by NorthernStar are described in section 3.1.9.2.

Access Roads and Hunt Creek Bridge

Clifton Road would be widened to a 24-foot paved surface with 2-foot shoulders on each side of the road. The first one-third mile would be a relatively straight-forward construction along relatively flat terrain. The majority of the next mile would require blasting rock from the uphill slope to widen the road prism by about 10 feet. The next 0.8 mile would require mechanically removing some ground from the uphill slope to widen the road prism. The final one-third mile, stopping 200 feet before the Bradwood Road intersection, would require that a Gabion retaining wall be constructed to widen the road prism. Additional culverts and drainage ditches would be installed to improve the drainage.

As discussed in section 2.1.3.6, Bradwood Road enters the LNG terminal site from Clifton Road over a bridge that crosses Hunt Creek. NorthernStar would need to improve and widen this 1,150-foot-long gravel access road for use during construction and operation of the proposed project. Bradwood Road would be surfaced in asphalt and widened from between 15 and 19.5 feet to 24 feet by clearing and grading the area directly adjacent to the existing roadway. The proposed roadway would generally follow the existing alignment, except immediately west of Hunt Creek Bridge; here the road would swing wider

onto the old second bridge alignment, where the old compacted, graded road area and pilings are still visible. The proposed roadway would be slightly wider than its current width and would extend approximately 170 feet past the existing alignment after crossing Hunt Creek as the roadway enters the LNG terminal. The roadway would not be curbed except where the new bridge's extruded concrete curb extends onto Bradwood Road.

The existing bridge over Hunt Creek is not adequate to withstand the anticipated loads associated with construction-related traffic. NorthernStar would replace the bridge with a new one built of four 75-foot-long, 3-foot-high, pre-cast concrete deck bulb T-girders (see figure 2.1.3-2). These would be supported on four 12-inch-diameter concrete-filled steel piles that would be placed above the mean higher high water (MHHW) elevation and driven using a vibratory hammer and completed with a cast-in-place pile cap. The new bridge deck elevation would be 2.4 feet above the 100-year flood elevation. The bridge decking would be asphalt. Cast-in-place concrete aprons would be added at the ends of the bridge to match the existing grade. Each side of the bridge would be curbed and have curb-mount rails. The bridge would be sloped to one side, and an additional 25 feet of extruded concrete curb would be constructed on each side beyond the concrete apron. This curb is designed to guide stormwater well beyond the ends of the bridge where it can be discharged into existing vegetation. Because the abutments would be placed well beyond the lateral extent of MHHW and the 2-year flood elevation, and because the lower reaches of Hunt Creek are largely tidally influenced by backwater from the Columbia River, within-channel flow velocities are expected to be sufficiently low, and bank and scour protection would not be necessary.

The abutments would be constructed outside of the lateral extent of both MHHW (at 9.45 feet NAVD 88) and the 2-year flood elevation on Hunt Creek (at 11.43 feet NAVD 88) to avoid in-water work. No in-water work is expected, with the possible exception of shortening the existing wooden piles if they interfere with the placement of the new bridge beams. In that event, the obstructing piles would be cut from a boat at a tide state above mean water level.

Railroad Line Realignment

An existing PWRR line runs through the proposed LNG terminal site. NorthernStar would need to remove a 4,200-foot-long portion of the existing tracks and relocate the railroad up to 250 feet south of its current alignment, still within the parcel controlled by NorthernStar. The right-of-way for the new railroad alignment would be 100 feet wide (i.e., 50 feet on each side of the centerline), consistent with the current right-of-way. Existing or new ballast would be moved or placed in the new right-of-way location and old tracks would be replaced by stronger new tracks. An undisturbed vegetation buffer zone would be maintained between the railroad realignment construction activities and the edge of Hunt Creek that would be at least 30 feet wide. The railroad line is in service, but not currently in use, which would allow for the possibility of delivering construction materials for the project by train.

Blasting

Blasting at the existing on-site rock quarry may be used to generate rock to be crushed for aggregate and sand to produce concrete and foundation bedding. Blasting would be conducted in accordance with all applicable federal, state, and local regulations. These regulations include *State of Oregon 2004 Fire Code Amendments*; *Explosives, Oregon's Revised Statutes, November 10, 2004*; and the Safe Explosives Act (27 CFR 555) or other more current regulations. NorthernStar would employ mitigation measures, as necessary, to minimize potential fly rock (i.e., using blasting nets/curtains) and to minimize vibration, noise, and safety impacts (i.e., coordinating with landowners in the project area). These mitigation measures would be detailed in a Blasting Management Plan, which NorthernStar would develop prior to beginning construction.

2.4.1.2 Maneuvering Area and Ship Berth

NorthernStar proposes to dredge about 700,000 cubic yards of material from approximately 46 acres within the 58-acre maneuvering basin area. The area would be dredged to a total depth of -43 feet CRD, which includes a 1-foot overdredge allowance. The sides of the dredged area would be cut to a 3 (horizontal) to 1 (vertical) slope. The dredging of the berth and maneuvering area would be performed using a hydraulic cutterhead (suction) dredge. Periodic dredging would be performed to maintain the berth and maneuvering area at the design water draft (see section 2.7.2).

The ship berth is expected to be constructed from the water using an offshore construction spread. The piling for the wharf would be constructed using an impact pile driver and a vibratory pile driver during the in-water work window. A 50-ton derrick barge and a 25-ton truck crane would be the primary construction equipment required, along with several barges used to stage rebar, forms, and other materials. The concrete would be pumped from shore through piping. Friction collars would be installed on the piles and the concrete forms, and rebar would be positioned to receive the concrete. Concrete would be delivered from shore into the completed forms to extend the wharf out into the water until the ship berth is constructed. Expandable foam would be used to seal the forms and ensure that uncured concrete is fully contained. Construction contractors would employ proven methods to ensure that uncured concrete and alkaline water from uncured concrete does not enter the river. The forms for the remote breasting and mooring dolphins would be constructed in a similar manner.

All in-water work associated with construction of the ship berth and unloading facilities is expected to take place between November 1 and February 28 (see section 4.5.2.1.).

2.4.1.3 LNG Storage and Support Facilities

One of the most technical aspects of the project would be installation of the LNG storage tanks and associated process and support facilities because specialized materials and construction techniques are necessary. Temporary construction pads would be completed before mobilization of the LNG storage tank components to serve as a laydown and staging area. Most of the equipment and components would be prefabricated and would require additional assembly, placement, and positioning once on site. Major pieces of construction equipment, including high lift and tower cranes, would be required for the erection of LNG storage tanks and other large components.

LNG Storage Tank Installation

The civil work for the foundation and pilings for the LNG storage tanks would follow immediately after the base soils have been stabilized. This process would involve vibroflotation to improve the liquefaction resistance of the soils. Vibroflotation, also known as vibrocompaction, is the compaction of loose granular soils by penetration of a vibratory probe. Water is typically jetted to aid the compaction process. The resulting void that develops is filled with clean sand or gravel that is compacted by the probe. The LNG storage tank foundations would consist of a 32-inch-thick reinforced concrete pile cap located on ground on a piled foundation. The piles, consisting of 402, 30-inch-diameter auger-cast concrete piles or driven steel piles approximately 165 feet long, would be located under each LNG storage tank.

The outer walls of the LNG storage tanks would consist of pre-stressed reinforced concrete with a wall thickness of at least 2 feet. A carbon steel prefabricated dome roof structure would be erected on top of the concrete tank outer wall to form a weather-protected space inside of the concrete outer tank. The base insulation and inner 9 percent nickel steel tank would then be constructed within this protected environment. Concrete would be poured over the steel dome to form the final roof structure.

Once the steel roof structure has been erected and welded in place, installation of the base insulation, secondary bottom, and inner 9 percent nickel steel tank would commence. Internal components consisting of vapor barrier, in-tank pump columns, instrument wells, bottom and top fill pipes, piping for purging and cool down, access ladders, and tank instrumentation would also be installed. Exterior equipment would include roof platforms, walkways, access stairway, and emergency escape ladder and piping.

Insulation of the LNG storage tanks would consist of base insulation, shell insulation, and suspended roof insulation. The base insulation material would consist of load-bearing cellular glass blocks and a concrete ring beam beneath the inner tank shell. After the inner tank is hydrostatically tested, the tank would be washed and cleaned. A resilient blanket would be installed on the outside of the inner wall of the tanks. Once the tank is completely sealed and the exterior is completely dry, expanded perlite would be used to fill in the annular space between the inner and outer tanks. A fiberglass blanket would be installed on the suspended deck above the inner tank to complete the insulation system.

Other Facility Construction

The other facilities such as processing areas, pipe racks, control rooms, utility areas, warehouse, instrument buildings, administrative offices and the gate house would be constructed concurrently with the LNG storage tanks. Foundations and pad areas would be established for each facility, and they would be constructed according to local building code requirements. These facilities would be ready for operation by the pre-commissioning stage.

Final Grading and Site Restoration

Areas disturbed during construction of the LNG terminal would be finish graded at an elevation of approximately 20 feet NAVD 88 using a layer of compacted crushed stone fill or other appropriate material. Unless covered by equipment, gravel, or other covering, areas disturbed during construction of the LNG terminal site would be restored in accordance with NorthernStar's terminal ESC Plan. Restoration of the shoreline would follow a conceptual plan that identifies specific revegetation practices depending on the vegetation zone (i.e., emergent zone, riparian low scrub zone, riparian shrub zone, and upland herbaceous zone). Revegetation of the shoreline would include using potted plants, emergent plugs, and broadcast seed mixes to establish native herbaceous and woody species within these zones.

2.4.1.4 Testing

NorthernStar would conduct testing of the LNG storage tanks and other facilities in accordance with applicable federal and state codes and standards. Some of the tests to be carried out are described below.

Hydraulic Testing of the LNG Storage Tanks

The inner container of the LNG storage tanks would be hydrostatically tested in accordance with the requirements of API 620. NorthernStar proposes to obtain the hydrostatic test water from the Columbia River using the terminal's permanent surface water intake and pumping station. The pumping station would be equipped with two 400 horsepower pumps, an electric primary pump and a diesel backup. The pumps would not operate simultaneously. The maximum water intake rate of each pump would be 4,400 gpm. Construction activities would be scheduled to enable water used to test the first tank to be reused to test the second tank, thus limiting the amount of water needed for hydrostatic testing of the tanks to approximately 30 million gallons. However, if construction does not proceed as planned, the two tanks may need to be tested at different times, in which case the amount of water needed for

hydrostatic testing of the tanks would be approximately 60 million gallons. The river water used for hydrostatic testing of the tanks would be filtered before use to remove suspended solids and tested for bacteria. If bacteria concentrations are high enough to cause corrosion of the steel tanks, the water would be chlorinated before use.

After hydrostatic testing of the LNG storage tanks is completed, the water would be discharged to the Columbia River through a temporary outfall extending approximately 300 feet offshore. If the water has been chlorinated, it would be dechlorinated before being discharged. NorthernStar does not expect that the hydrostatic test water from the tanks would need to be further treated before discharge to the river. However, all batches of tank hydrostatic test water would be sampled and analyzed before discharge and treated as necessary to enable safe discharge to the river.

Pneumatic Testing of the LNG Storage Tanks

Each tank would also be pneumatically tested at a pressure of 1.25 times the design pressure for 1 hour in accordance with API 620.

Hydraulic/Pneumatic Testing of Piping Systems

Piping systems would be tested in accordance with established codes either hydraulically or pneumatically, as applicable. In general, cryogenic piping would be tested with dry air or nitrogen at 1.1 times the design pressure. Non-cryogenic piping would be tested with water at 1.5 times the design pressure. Water required for the hydrostatic testing of piping (approximately 1.5 million gallons) would be obtained from the on-site groundwater well. The well water would not be treated before it is used for hydrostatic testing of piping.

After use, the hydrostatic test water from the piping would be discharged to the ground or occasionally to the Columbia River through a temporary outfall. NorthernStar does not expect that the hydrostatic test water from the piping would need to be treated before discharge to the river. However, all batches of water used for hydrostatic testing of piping would be sampled and analyzed before discharge and treated as necessary to enable safe discharge to the river.

2.4.2 Pipeline and Associated Aboveground Facilities

Construction of the proposed pipeline would primarily involve standard cross-country pipeline construction techniques as described in section 2.4.2.1. Special construction techniques would also be used when constructing the pipelines across wetlands; waterbodies; roads and railroads; foreign pipelines; and agricultural, residential, commercial, and industrial areas. Rugged terrain also may require special construction techniques. These special construction techniques are described in section 2.4.2.2. Construction of the aboveground facilities associated with the pipeline is discussed in section 2.4.2.3.

2.4.2.1 General Pipeline Construction Techniques

Figure 2.4.2-1 shows the typical steps of cross-country pipeline construction. Standard pipeline construction proceeds in the manner of an outdoor assembly line composed of specific activities that make up the linear construction sequence. These operations collectively include survey and staking of the right-of-way, clearing and grading, trenching, pipe stringing and bending, welding and coating, lowering-in and backfilling, hydrostatic testing, and cleanup.

- 1) Survey and Staking
- 2) Clearing
- 3) Front-End Grading
- 4) ROW Topsoil Stripping
- 5) Restaking Centerline of Trench
- 6) Trenching (wheel ditcher)
- 7) Trenching (rock)

- 18) As-Built Survey
- 19) Pad, Backfill, Rough Grade
- 20) Hydrostatic Testing, Final Tie-In
- 21) Replace Topsoil, Final Clean-Up, Full Restoration

Figure 2.4.2-1
Bradwood Landing Project
 Typical Pipeline Construction Sequence

Survey and Staking

Before construction, NorthernStar's crews would survey and stake the centerline and exterior boundaries of the construction right-of-way. The exterior boundary stakes would mark the limit of approved disturbance areas and would be maintained throughout the construction period. Utility lines would be located and marked to prevent accidental damage during pipeline construction. NorthernStar would notify affected landowners, regulatory agencies, and other appropriate stakeholders before surveying and staking the proposed route. Survey and staking conditions of the NPDES Construction Stormwater Permit would be met.

Clearing and Grading

NorthernStar would clear the right-of-way of large obstacles such as trees, brush, and logs. Timber would be removed when necessary for construction purposes. Timber and other vegetative debris may be chipped for use as erosion-control mulch, or otherwise disposed of in accordance with applicable state and local regulations and landowner crossing agreements. Fences would be cut and braced along the right-of-way and temporary gates would be installed to control livestock and limit public access. The right-of-way would then be graded where necessary to create a reasonably level working surface to allow safe passage of construction equipment and materials. Where applicable (e.g., residential and agricultural lands), conserved topsoil would be stockpiled along one side of the right-of-way, allowing the other side to be used for access, material transport, and pipe assembly. NorthernStar would install temporary erosion control measures at this time.

Trenching

A rotary trenching machine, rock trencher, track-mounted backhoe, or similar equipment would be used to excavate a trench to a sufficient depth to provide a minimum 3-foot depth of cover. Depending on soil conditions, the top of the trench could be up to 25 feet wide and the bottom of the trench would typically be at least 12 inches wider than the diameter of the pipe (i.e., 42 inches wide for the 30-inch-diameter pipe and 48 inches wide for the 36-inch-diameter pipe). The sides of the trench would be sloped for stability and safety.

Spoil material excavated during trenching operations would be temporarily piled to one side of the right-of-way adjacent to the trench. In areas where topsoil stripping is required, the topsoil and subsoil would be stored in separate windrows or piles on the construction right-of-way and would not be allowed to mix.

Where the pipeline route is adjacent to an existing pipeline, the subsoil spoil would be placed on the same side of the trench as, but not directly over, the existing pipeline to keep working equipment off of the operating pipeline. In these collocated sections, the topsoil would be stockpiled on the working side of the right-of-way, outside the construction equipment lane.

Stringing and Bending

Either before or after trenching, 80-foot-long sections of externally coated pipe (also referred to as joints) would be shipped to the pipe storage and contractor yards and then transported to the right-of-way by truck and placed or "strung" along the excavated trench in a single, continuous line, easily accessible to the construction personnel on the working side of the trench, opposite the spoil side. At crossings of streams, railroads, and highways the amount of pipe required to span the crossing would be stockpiled in temporary staging areas on one or both sides of the crossing.

The pipe would be delivered to the construction right-of-way in straight joints. Some bending of the pipe would be required to allow the pipeline to follow natural grade changes and direction changes of the right-of-way. Selected joints would be bent in the field by track-mounted hydraulic bending machines, as necessary, before welding.

Welding and Coating

After stringing and bending are complete, pipe sections would be placed on temporary supports adjacent to the trench. The ends would be aligned and welded together using multiple passes for a full penetration weld. Only qualified welders would be permitted to perform the welding. Welders and welding procedures would be qualified according to the API Standard 1104 or the American Society of Mechanical Engineers Boiler and Pressure Vessel Code.

To ensure that the assembled pipe meets or exceeds the design strength requirements, NorthernStar would inspect all welds, both visually and radiographically (i.e., x-ray) or other nondestructive method if x-ray is impractical, and would make any necessary repairs. Following weld inspection, the previously uncoated ends of the pipe at the welds would be epoxy coated. The coating on the completed pipe section would be inspected and any damaged areas repaired.

Lowering-in and Backfilling

After welding and coating are completed, the pipe would be lowered into the trench by side-boom tractors. Before lowering the pipe, the trench would be inspected to ensure that it is free of rocks and other debris that could damage the pipe or the coating. In addition, the pipe and trench would be inspected to ensure that the configurations of the pipe and trench configurations are compatible.

Bladed equipment or a specially designed backfilling machine would be used to backfill the trench. No construction debris, including wooden supports, welding rods, containers, brush, trees, or refuse of any kind, would be permitted in the backfill. If rocks or other materials that could damage the pipe or coating are present in the backfill, a padding machine would be used to separate the rock from the backfill. In some instances, clean fill or additional protective coating such as rock shield would be placed around the pipe before backfilling.

Segregated topsoil, where applicable, would be replaced after backfilling the trench with subsoil. Following backfilling, a small crown of material would be left to account for any future soil settling that might occur.

Hydrostatic Testing

After backfilling, NorthernStar would hydrostatically test the pipeline in accordance with DOT regulations to ensure that the system is capable of operating at the design pressure. The testing process involves filling a segment of the pipeline with water and maintaining a prescribed pressure for a specified amount of time. If a leak or break in the line were to occur during testing, NorthernStar would repair and retest that section of pipe until DOT specifications are met.

A total of approximately 9.0 million gallons of water would be withdrawn from the Columbia River to hydrostatically test the pipeline. However, an additional 0.5 million gallons may be required to account for any water losses and make-up water. This water would be acquired from the Oregon side of the Columbia River at the location where the pipeline construction right-of-way meets the river. The water would be supplied via temporary piping connections from the source area or transported by tanker truck. No chemicals would be added to the test water. The water would be discharged through a straw

bale enclosure to the ground surface at an upland site near the river withdrawal location. If the construction sequence allows, the same water used for testing the Bradwood Landing pipeline may be used to test the Bradwood Landing LNG storage tanks to conserve water. Each segment of the pipeline to be installed by the HDD method would be initially hydrostatically pressure tested separately from the overall pipeline before and after installation in the borehole, then included in the overall pipeline pressure test once all the HDD segments are tied into the pipeline.

Meter assemblies would be built and tested separately from the pipeline. This usually occurs in contractor yards and involves relatively small volumes of water.

Cleanup

After a segment of pipe has been installed, backfilled, and successfully tested, the right-of-way, temporary extra workspaces, and other disturbed areas would be finish graded and the construction debris would be taken to an approved disposal area. NorthernStar would finish-grade the right-of-way to match the contour of adjacent undisturbed areas. In agricultural areas, compacted subsoil would be disked and the segregated topsoil would be replaced. Temporary and permanent erosion control measures, including diversion terraces and revegetation, would be installed at this time. Private and public property, such as fences, gates, driveways, and roads disturbed by the pipeline construction would be restored.

Revegetation

The restored construction right-of-way would be revegetated in accordance with NorthernStar's pipeline ESC Plan for Oregon and SWPPP for Washington, the FERC staff's Plan, other permit requirements, and site-specific landowner requests. Turf, ornamental shrubs, and other landscaping material would be restored in accordance with individual landowner agreements.

2.4.2.2 Special Pipeline Construction Techniques

Construction across wetlands; waterbodies; roads and railroads; foreign pipelines and utilities; agricultural, residential, commercial, and industrial areas; and rugged terrain may require special construction techniques. Special techniques would also be used if blasting is required. These techniques are described below. Additional detail on wetland and waterbody crossing construction techniques is provided in the *Bradwood Landing Pipeline Waterbody and Wetland Construction and Mitigation Procedures Plan*.⁴

Wetland Crossings

NorthernStar would construct its pipeline across wetlands in accordance with the FERC staff's Procedures and applicable permits. During crossing of unsaturated wetlands (i.e., wetlands without standing water or saturated soils), construction would be similar to the upland construction described above. If the crossing is less than 100 feet long, NorthernStar has requested the use of an 85-foot-wide construction right-of-way. In these areas, excavated material could be effectively moved to the adjacent upland spoil storage areas within the right-of-way. Where wetland crossings are longer than 100 feet, NorthernStar has requested use of a 100-foot-wide construction right-of-way. Section 4.4.1.3 describes these proposed modifications to the FERC Staff's Procedures in greater detail.

⁴ NorthernStar submitted the *Bradwood Landing Pipeline Waterbody and Wetland Construction and Mitigation Procedures Plan* to the FERC on December 21, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, by selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

Where necessary to prevent rutting or mixing of topsoil and subsoil, a temporary board road would be installed to allow passage of equipment with minimal disturbance of the surface and vegetation in wetlands. Trees would be cut to grade, but stumps would only be removed within 15 feet of the edge of the pipe trench, or where safety concerns dictate otherwise. Topsoil over the pipe trench would be segregated from subsoils. A riparian buffer would be left between the wetland and the upland construction areas except for the pipe trench itself and erosion control measures (e.g., silt fences, interceptor levees, and hay bale structures) would be installed and maintained to minimize sedimentation into the wetland. Trench plugs would be installed where necessary to prevent the unintentional draining of water from the wetland. After construction, forested wetlands would be replanted in-kind with trees, with the exception of the portion of the right-of-way within 5 feet of the pipeline (10 feet total), thereby minimizing the extent of disturbance. NorthernStar's proposed tree planting exceeds the revegetation requirements of the FERC staff's Plan and Procedures. The corridor centered on the pipeline would be planted with a native grass seed mix and maintained in an herbaceous state to facilitate maintenance and inspection. Wetlands might also be crossed using the HDD construction method described below.

Waterbody Crossings

NorthernStar would cross small perennial and intermediate waterbodies in accordance with the FERC staff's Procedures and the proposed alternative measures described in section 4.4.1.3 as well as applicable permits. Intermittent streams that are dry at the time of crossing would be crossed using conventional upland construction techniques described above. The stream volume and velocity and available backfill materials would be considered in establishing the depth of cover over the pipeline in each stream in order to minimize the potential for scour and the ultimate exposure of the pipeline. Section 4.3.2.4 lists the proposed method for crossing all of the waterbodies along the pipeline route. Some waterbodies, including the Columbia River, would be crossed using the HDD method described below. Others would be crossed using open-cut or conventional bore methods. No bank hardening (e.g., riprap) is proposed to be used at any crossing.

NorthernStar would use two types of open-cut methods, the flume method and the dam and pump method. The flume method (see figure 2.4.2-2) is a standard dry waterbody crossing construction method that involves diverting the flow of water across the trenching area through one or more flume pipes placed in the waterbody. The first step in the flume crossing method would involve placing a sufficient number of adequately sized flume pipes in the waterbody to accommodate the highest anticipated flow during construction. Before the flume pipe is installed at the waterbody, it would be inspected to ensure it is free of dirt, grease, oil, or other pollutants. Excessive dirt would be removed. The pipe would be steam-cleaned, if necessary, to remove any oil or grease present before placement in the stream.

After placing the pipe in the waterbody, sand or pea gravel bags, water bladders, or metal wing deflectors would be placed in the waterbody upstream and downstream of the trench area. These devices would serve to dam the stream and divert the water flow through the flume pipes, thereby isolating the water flow from the construction area between the dams. Several measures would be taken to minimize short-term increases in turbidity during dam construction, including: 1) all in-stream work would be carried out on foot and no equipment would operate in the streambed; 2) sandbags would be filled with a non-leachable material such as clean, prewashed sand; 3) sandbags would be tied securely before they are installed; and 4) sheets of plastic would be interwoven between the layers of sandbags to ensure an effective seal. Leakage from the dams or subsurface flow from below the waterbody bed may cause water to accumulate in the isolated area. If necessary, the accumulated water would be periodically pumped out and discharged into energy dissipation/sediment filtration devices, such as a geotextile filter bag or straw bale structure, or into well-vegetated areas away from the water's edge.

Figure 2.4.2-2
Bradwood Landing Project
 Flume Waterbody Crossing Method

Trackhoes located on both banks of the waterbody would excavate a trench under the flume pipe in the dewatered streambed. Spoil excavated from the waterbody trench would be placed or stored a minimum of 10 feet from the edge of the waterbody. Once the trench is excavated, the prefabricated segment of pipe would be installed beneath the flume pipes. The trench would then be backfilled with native spoil from the waterbody bed. Immediately following pipe installation and backfilling, and before removing the dams and flume pipes and returning flow to the waterbody channel, the streambanks would be reestablished to approximate preconstruction contours and stabilized. Erosion and sediment control measures would be installed across the construction right-of-way to reduce streambank and upland erosion and sediment transport into the waterbody. Sediment barriers, such as silt fence and/or straw bales or drivable berms would be maintained across the right-of-way at all waterbody approaches until permanent vegetation is established. After backfilling and major grading work are complete, any drivable berms would be removed and the ground surface returned to original contours. If a sediment control device is still needed at a location where a drivable berm was removed, a temporary sediment control device such as silt fencing would be installed. Equipment bridges would be removed when construction and restoration are completed.

The dam and pump method (see figure 2.4.2-3) is a standard dry waterbody crossing construction method that may be used as an alternative to the flume method for waterbodies less than 10 feet wide. This method is similar to the flume crossing method except that pumps and hoses would be used instead of flumes to move water across the construction work area. The technique involves damming of the waterbody with sandbags and/or steel plates upstream and downstream of the trench area. Pumps would be set up at the upstream dam with the discharge line routed through the construction area to discharge water immediately downstream of the downstream dam. An energy-dissipation device would be used to prevent scouring of the streambed at the discharge location. Water flow would be maintained through all but a short reach of the waterbody at the actual crossing. The pipeline would be installed and backfilled. After backfilling, the dams would be removed and the banks restored and stabilized. For both open-cut crossing techniques, the top 12 inches of substrate would be segregated for each crossing and returned. If additional material is needed, matching material would be utilized.

NorthernStar proposes to cross at least three waterbodies and up to seven waterbodies using a conventional bore, which is similar to the HDD method in that the pipeline is installed beneath a feature without surface disturbance to the feature during the crossing. However, the bore method differs in that the path of the pipeline across the feature is straight and is not variable or directional as in an HDD borehole where the path is curved or arched. The maximum length of a bore (hundreds of feet) is also much less than the maximum length of an HDD borehole (thousands of feet). Boring is frequently utilized at paved road and railroad crossings and is not a common crossing method for waterbodies primarily because of the difficulty in managing groundwater during the installation.

Boring requires excavation of pits on each side of the feature. Boring operations would require relatively large work areas, and well points or pumping for continuous dewatering operations, and may require continuous spoil/slurry processing throughout construction of the crossing. During a standard boring operation, spoil from the bore is carried into the pit as the crossing is being completed and then removed by trackhoes to provide room for the pipe to be welded and eventually pulled through the borehole. The operator for the boring machine, welders, and several laborers would work in the bore pit. Trench boxes or sheet piling may be used to support the pit walls and to help cut off groundwater inflows. Dewatering systems using deep wells or well points are frequently employed. The specific type of bore (e.g., jack and bore, slick bore, hammer bore) that would be utilized in a given area depends on the construction site characteristics, the type of soils present, and the contractor's familiarity with available methods.

Figure 2.4.2-3
Bradwood Landing Project
 Dam and Pump Waterbody Crossing Method

Horizontal Directional Drilling

NorthernStar proposes to cross selected wetlands, waterbodies, selected upland habitats, and roads using the HDD construction method. This technique involves drilling a pilot hole under the waterbody, then enlarging that hole through successive reamings until the hole is large enough to accommodate the pipe. Throughout the process of drilling and enlarging the hole, a slurry made of naturally occurring non-toxic materials, such as bentonite clay and water, would be circulated through the drilling tools to lubricate the drill bit, remove drill cuttings, and hold the hole open. This slurry is referred to as drilling mud. NorthernStar has indicated it would use a drilling mud consisting of 95 percent water and 5 percent bentonite. Pipe sections long enough to span the entire crossing would be staged and welded along the construction work area on the opposite side of the waterbody and then pulled through the drilled hole. Figure 2.4.2-4 shows a conceptual HDD waterbody crossing.

Roads and Railroads

NorthernStar would install the pipeline under major paved highways and railroads where traffic cannot be interrupted using the HDD or bore method. Both of these methods would proceed as they would for a waterbody crossing discussed above.

Smaller unpaved roads and driveways would be crossed by the traditional open-cut method. After construction, these roads and driveways would be restored. If an open-cut road crossing requires extensive construction time, NorthernStar would make provisions for temporary detours or other measures to allow safe traffic flow during construction. The pipeline would be buried to a depth of at least 5 feet below road surfaces or as required by applicable permits, and 10 feet below the toe of railroad embankments (or as otherwise required by the railroad company), and would be designed to withstand anticipated external loadings. Casings would be installed only where specifically required by permitting authorities.

Foreign Pipelines and Utilities

The proposed pipeline would cross several foreign pipelines. Additional foreign pipelines and other underground utilities are likely to be discovered during the preconstruction shallow hazards survey. Because of the relatively large size of the proposed pipeline and the soil cover and separation requirements, NorthernStar would cross under most foreign pipelines and utilities. Additional temporary workspace would be used at these crossings to accommodate the increased amount of spoil resulting from the need to excavate a deeper trench, and to prevent spoil and construction equipment from being placed over the existing pipelines. NorthernStar has indicated that it would ensure that the existing pipelines and utilities are not damaged during construction of its pipeline. Furthermore, NorthernStar would comply with state statutes (i.e., for Oregon: OAR 952-001-0010 through OAR 952-001-0090 – Oregon Utility Notification Center and for Washington: Chapter 19.122 RCW) which establish protocols and requirements for coordinating excavation work with operators of existing underground utilities.

Agricultural Areas

NorthernStar would conserve topsoil in actively cultivated and rotated cropland, improved pastureland, non-saturated wetlands, and rangeland. NorthernStar would segregate a maximum of 12 inches of topsoil in these areas, as well as in other areas at the specific request of the landowner or land management agency. The topsoil would be temporarily stockpiled separate from the subsoil within the construction right-of-way. Where topsoil is less than 12 inches deep, the actual depth of the topsoil would be removed and segregated. The trench would be excavated to a sufficient depth to allow for at least 3 feet of cover on top of the pipe.

For environmental review purposes only.

Figure 2.4.2-4
Bradwood Landing Project
Conceptual Horizontal Directional Drill Waterbody Crossing

The FERC staff's Plan requires that an applicant consult with landowners and local soil conservation organizations to locate existing drain tiles and irrigation systems in agricultural lands along the proposed pipeline route. The applicant needs to develop measures for constructing through drain tiled areas, maintaining irrigation systems during construction, and repairing drain tiles and irrigation systems after construction.

Residential Areas

NorthernStar's proposed construction work area (i.e., construction right-of-way and extra work areas) would be located within 50 feet of three residential structures, which are all located in Columbia County, Oregon. The potential impact the proposed sendout pipeline may have on residences is discussed in section 4.7.3.3. NorthernStar would prepare site-specific residential construction mitigation plans that detail the specific measures that would be used when construction occurs near residences. In general, where residences are within 50 feet of the edge of the construction work area, NorthernStar would fence the edge of the construction right-of-way, limit construction to daylight hours, backfill immediately after pipe installation, preserve landscaping where possible, and restore the construction area to the satisfaction of the landowner.

Commercial and Industrial Areas

Impacts on commercial and industrial areas would be limited to the construction and post-construction restoration periods when construction activities could inconvenience business owners, employees, and customers. NorthernStar would coordinate closely with business owners to maintain access, decrease construction duration, and generally minimize impacts on these areas.

Rugged Terrain

Portions of the proposed pipeline would cross rugged terrain, consisting of steep slopes and substantial changes in elevation. Additional grading may be required in areas where the pipeline route crosses steep slopes. Steep slopes often need to be graded down to a gentler slope to accommodate pipe bending limitations. In such areas, the slopes would be cut away, and, after the pipeline is installed, reconstructed to their original contours during restoration. In areas where the pipeline route crosses laterally along the side of a slope, cut and fill grading may be required to obtain a safe, flat work terrace. Steep slopes may also require the installation of special erosion control measures, including trench breakers, slope breakers, interception dikes, and erosion control mats to prevent the movement of disturbed soil off the right-of-way.

Blasting

It is likely that shallow bedrock is present in some areas along the proposed pipeline route. Currently, NorthernStar expects that any subsurface rock that is encountered along the pipeline route could be trenched using conventional equipment (e.g., trackhoes, rippers, or rock trenchers). As such, the use of blasting for pipe trench excavation is not expected to be necessary. If blasting does become necessary, mitigation measures described in the Blasting Management Plan (see section 2.4.1.1) would be implemented. Care would be taken to prevent damage to underground structures (e.g., cables, conduits, sewers, foundations, basements, and pipelines) and to springs, water wells, or other water sources. Blasting mats, soil cover, or other safety precautions would be used as necessary to prevent the scattering of loose rock. All blasting would be conducted during daylight hours and would not begin until occupants of nearby buildings, stores, residences, places of business, and farms have been notified and the area has been cleared of unauthorized persons. Only qualified and properly licensed personnel would be

allowed to handle explosives and conduct blasting activities. All blasting would be conducted in accordance with applicable federal, state, and local codes and ordinances.

2.4.2.3 Associated Aboveground Facilities

Interconnect/Meter Station Sites

During installation of the interconnect sites, construction activities and storage of construction materials and equipment would be confined to the pipeline construction right-of-way or approved temporary workspace. NorthernStar would dispose of debris and waste generated during the construction and all disturbed surface areas would be restored.

NorthernStar would excavate as necessary to accommodate the new reinforced concrete foundations for the new metering equipment, pigging facilities, and buildings. Forms would be set, rebar installed, and the concrete poured and cured in accordance with applicable industry standards. Backfill would be compacted in place, and excess soil would be used elsewhere or distributed around the site to improve grade.

Metering equipment would be delivered to the site by truck; unloaded using cranes, front-end loaders, or both, and positioned on the foundations, leveled, grouted where necessary, and secured with anchor bolts. After installation, all controls and safety equipment and systems, including ESD, relief valves, and gas and fire detection equipment, would be checked and tested, before being placed in service. Each of the interconnect sites would be fenced and graveled.

Pig Launchers and Receivers

A pig launcher would be installed at MP 0.0 at the LNG terminal. A pig launcher and receiver would be installed where the pipeline transitions from 36 inches in diameter to 30 inches in diameter at MP 18.8. A pig receiver would be installed at the Williams Northwest interconnect at MP 36.3. NorthernStar would install these facilities using the same standards and requirements established for construction of its proposed pipeline. The pigging facilities would be fenced and graveled after construction is completed.

Mainline Block Valves

MLVs would be installed at the pipeline origination at the pig launcher site within the LNG terminal, within the Williams Northwest interconnect site at the pipeline terminus, and within the pipeline right-of-way at several intermediate locations. The locations of the MLVs would be in accordance with the requirements in 49 CFR 192. NorthernStar would install these facilities using the same standards and requirements established for construction of its proposed interconnect sites and pipeline. The intermediate MLV sites would be fenced and graveled after construction is completed.

2.5 CONSTRUCTION SCHEDULE

No work would begin until the required permits and approvals are in place. NorthernStar indicates that it would require about 36 months to construct the proposed facilities. Construction and testing of the LNG tanks would require the most time. Construction of the pipeline and associated aboveground facilities would occur during the second year of constructing the LNG terminal facilities and require about 7 months to complete.

2.6 ENVIRONMENTAL COMPLIANCE INSPECTION AND MITIGATION MONITORING

In preparing construction drawings and specifications for the project, NorthernStar would incorporate mitigation measures identified in its application as well as requirements of federal, state, and local agencies. Contractors would also be provided copies of applicable environmental permits.

NorthernStar would conduct training for its construction personnel regarding proper field implementation of its ESC Plans, SWPPP, our Plan and Procedures, and other mitigation measures. Environmental training would be conducted before and during construction.

NorthernStar would be represented on each pipeline spread by a Chief Inspector, who would be responsible for quality assurance and compliance with mitigation measures, other applicable regulatory requirements, and company specifications. The Chief Inspector would be assisted by one or more craft inspectors and at least one full-time Environmental Inspector during construction of the pipeline. The Environmental Inspector would report directly to the Chief Inspector and would have stop-work authority. The Environmental Inspector's responsibilities would include:

- ensuring compliance with the requirements of the Plan, Procedures, the environmental conditions of the section 3 and Certificate authorization, the mitigation measures proposed by the applicant (as approved and/or modified by the FERC's authorization), other environmental permits and approvals, and environmental requirements in landowner easement agreements;
- identifying, documenting, and overseeing corrective actions, as necessary to bring an activity back into compliance;
- verifying that the limits of authorized construction work areas and locations of access roads are properly marked before clearing;
- verifying the location of signs and highly visible flagging marking the boundaries of sensitive resource areas, waterbodies, wetlands, or areas with special requirements along the construction work area;
- identifying erosion/sediment control and soil stabilization needs in all areas;
- ensuring that the location of dewatering structures and slope breakers would not direct water into known cultural resources sites or locations of sensitive species;
- verifying that trench dewatering activities do not result in the deposition of sand, silt, and/or sediment near the point of discharge into a wetland or waterbody. If such deposition is occurring, the dewatering activity would be stopped and the design of the discharge would be changed to prevent reoccurrence;
- ensuring that subsoil and topsoil are tested in agricultural and residential areas to measure compaction and determine the need for corrective action;
- advising the Chief Construction Inspector when conditions (such as wet weather) make it advisable to restrict construction activities to avoid excessive rutting;
- ensuring restoration of contours and topsoil;

- verifying that the soils imported for agricultural or residential use have been certified as free of noxious weeds and soil pests, unless otherwise approved by the landowner;
- determining the need for and ensuring that erosion controls are properly installed, as necessary, to prevent sediment flow into wetlands, waterbodies, sensitive areas, and onto roads;
- inspecting and ensuring the maintenance of temporary erosion control measures at least:
 - on a daily basis in areas of active construction or equipment operation;
 - on a weekly basis in areas with no construction or equipment operation; and
 - within 24 hours of each 0.5 inch of rainfall;
- ensuring the repair of all ineffective temporary erosion control measures within 24 hours of identification;
- keeping records of compliance with the environmental conditions of the FERC certificate, and the mitigation measures proposed by the project sponsor in the application submitted to the FERC, and other federal or state environmental permits during active construction and restoration; and
- identifying areas that should be given special attention to ensure stabilization and restoration after the construction phase.

In addition, the FERC staff would conduct inspections to monitor the project for compliance with the Commission's environmental conditions and project mitigation measures proposed by NorthernStar or required by the regulatory agencies. To assist the FERC with its independent monitoring responsibilities during construction of this project, **we recommend that:**

- **NorthernStar should develop and fund a third-party environmental monitoring program to be implemented during construction of the Bradwood Landing Project. The program should allow for on-site, third-party compliance monitors representing the FERC to be present full-time during all pipeline construction phases, and periodically during LNG terminal construction, to ascertain that the project is being built as outlined in this EIS, and in accordance with the environmental conditions of the FERC Order. Prior to construction, NorthernStar should file a plan describing the third-party environmental monitoring program with the Secretary of the Commission (Secretary) for the review and written approval of the Director of OEP.**

Finally, other federal, state, and local agencies with jurisdiction or permitting authorities would conduct oversight inspections and monitoring to the extent deemed necessary by those agencies in order to meet their regulatory responsibilities.

2.7 OPERATION AND MAINTENANCE PROCEDURES

2.7.1 LNG Marine Traffic along the Waterway

Although LNG carriers and their operation are directly related to the use of the proposed import terminal, they are not subject to the section 3 authorization sought in this application. The LNG carriers arriving at the proposed LNG terminal must comply with all federal and international standards regarding

LNG shipping. A detailed discussion of design and safety features of LNG carriers is presented in sections 2.1.1.6 and 4.11.5.

LNG carriers would enter the Columbia River under the navigational control of a Columbia River Bar Pilot; the control would transfer to a Columbia River Pilot at Astoria. The pilots would decide whether the wave, visibility, tide, current, and wind conditions allow safe entry into the Columbia River and onward to the LNG terminal. The LNG carrier would transit the waterway with a two-tug escort, with three tugs used to maneuver the carrier within the turning basin and to dock at the terminal berth. The pilot would direct the securing of the lines and would turn navigational control back to the captain when the carrier is fastened.

The Coast Guard's WSR outlines conditions for LNG marine traffic in the waterway, including additional resources or assets that would be required prior to allowing LNG carriers to transit up the Columbia River to the Bradwood Landing LNG terminal. Safety and security measures relating to LNG marine traffic are described in more detail in section 4.11.5.

All LNG carriers would be required to carry Coast Guard-approved vessel response plans and comply with state spill prevention and contingency plans, including the applicable requirements in Chapter 317-40 of the WAC – Bunkering Operations.

The COE would be responsible for maintenance dredging of the navigation channel in the Columbia River. NorthernStar would be responsible for maintenance dredging of its turning basin and maneuvering area. NorthernStar estimates about 80,000 cubic yards of material would be removed from the maneuvering area every 2 to 4 years in order to maintain a depth of between 42 and 43 feet as part of maintenance dredging. NorthernStar expects the maintenance dredging would be carried out when the maneuvering area level reaches 42 feet CRD. Material from maintenance dredging would be deposited at the Wahkiakum County Sand Pit site located at the northern end of Puget Island (see section 3.1.9.2) or some other approved dredge disposal site. Each round of maintenance dredging would take about 2 weeks and would be accomplished using a hydraulic cutterhead suction dredge if placement is at the Sand Pit site. If a different dredge material disposal site is used, a clamshell/barge or hopper dredge would be necessary. NorthernStar has requested a permit for maintenance dredging from the COE that would cover the first 5 years of the LNG terminal operation.

2.7.2 LNG Terminal Facilities

NorthernStar would operate and maintain its facilities in compliance with 49 CFR 193.2503 and 193.2605 and sections 11.3.1 and 11.5.2 of NFPA 59A, 33 CFR 127, and other applicable federal and state regulations. Before commencing operation of the LNG terminal, NorthernStar would prepare and submit for approval operation and maintenance manuals that address specific procedures for the safe operation and maintenance of the LNG storage and processing facilities. NorthernStar would also prepare an operations manual that addresses specific procedures for the safe operation of the ship unloading facilities in accordance with 33 CFR 127.305. Operating procedures would address normal operations as well as safe startup, shutdown, and emergency conditions.

All operations and maintenance personnel at the LNG terminal would be trained to properly and safely perform their assignments. The terminal operators would be trained in LNG safety, cryogenic operations, and the proper operation of respective terminal control equipment. The operators would be required to meet all the training requirements of the DOT, Coast Guard, and other applicable regulatory entities. Operating personnel would be on duty at the terminal 24 hours per day, 7 days per week. Two operators per shift would work in the control room. In addition, one or two operators would be available to perform manual operating tasks at the processing and storage areas.

NorthernStar would maintain a full-time, maintenance staff to perform routine maintenance and minor overhauls at the LNG terminal. Major overhauls and major maintenance activities would be handled by trained and qualified contract personnel. All maintenance activities, including scheduled preventative and predictive maintenance and unscheduled maintenance, would be managed through a computerized maintenance management system (CMMS). Scheduled preventative and predictive maintenance would be inputted into the CMMS before commissioning of each piece of equipment. Unscheduled maintenance would be entered into the CMMS by the qualified personnel identifying the need. NorthernStar would train all facility operations and maintenance personnel on the use of the CMMS.

2.7.3 Pipeline and Associated Aboveground Facilities

The pipeline and associated aboveground facilities would be operated and maintained in accordance with 49 CFR 192, *Transportation of Natural and Other Gas by Pipeline: Minimum Federal Safety Standards*, as required by the DOT. Section 4.11.9 presents a discussion of the DOT's safety regulations and requirements for natural gas pipelines and describes how these requirements would be met by the pipeline operator.

The pipeline would be inspected regularly by aerial patrols or on-the-ground personnel to observe general right-of-way conditions and to identify any indications of soil erosion that may expose the pipe, stressed vegetation that may indicate a leak in the line, damage to erosion-control structures, unauthorized encroachment onto the right-of-way, and other conditions that could present a safety hazard or require preventive maintenance or repairs. All inspections would be in accordance with DOT requirements. Appropriate responses to conditions observed during the periodic inspections would be taken as necessary.

The aboveground facilities would be inspected at intervals that meet DOT requirements. Pipeline personnel would perform routine checks of the facilities, including calibration of equipment and instrumentation, inspection of critical components, and scheduled and routine maintenance of equipment. Safety equipment, such as pressure-relief devices, fire detection and suppression systems, and gas detection systems, would be tested for proper operation. Corrective actions would be taken for any identified problem.

2.8 SAFETY CONTROLS

2.8.1 LNG Terminal Facilities

The LNG terminal facilities would be sited, designed, constructed, operated, and maintained in compliance with federal safety standards. The major federal siting and design requirements for LNG facilities are summarized in table 2.8.1-1.

2.8.1.1 Spill Containment

The LNG impoundment systems for the terminal facilities would be designed and constructed to comply with DOT regulations (49 CFR 193.2149 through 193.2185). These regulations require that each LNG container and each LNG transfer system be provided with a means of secondary containment that has been sized to hold the quantity of LNG that could occur as a result of the design spill that is appropriate for the area and LNG equipment. The design spills are defined in NFPA 59A.

TABLE 2.8.1-1 Federal Siting and Design Requirements for LNG Facilities	
Requirement	Description
Thermal Radiation Protection (49 CFR 193.2057 and section 2.2.3.2 of NFPA 59A)	This requirement is designed to ensure that certain public land uses and structures outside the LNG facility boundaries are protected in the event of an LNG fire.
Flammable Vapor-Gas Dispersion Protection (49 CFR 193.2059 and sections 2.2.3.3 and 2.2.3.4 of NFPA 59A)	This requirement is designed to prevent a flammable vapor cloud associated with an LNG spill from reaching a property line that can be built upon.
Seismic Design (49 CFR 193.2101, and NFPA 59A)	This requirement outlines the necessary site specific seismic hazard study and specifies that critical safety-related components of the facility must be designed to survive earthquake ground motions estimated to have a 1 to 2 percent probability of occurring within a 50-year period.
Wind Forces (49 CFR 193.2067)	This requirement specifies that all facilities be designed to withstand wind forces of not less than 150 mph without the loss of structural integrity.
Impounded Liquid (section 2.2.3.8 of NFPA 59A)	This requirement specifies that liquids in spill impoundment basins cannot be closer than 50 feet from a property line that can be built upon or a navigable waterway.
Container Spacing (section 2.2.4.1 of NFPA 59A)	This requirement specifies that LNG containers with capacities greater than 70,000 gallons must be located a minimum distance of 0.7 times the container diameter from the property line or buildings.
Vaporizer Spacing (section 2.2.5.2 of NFPA 59A)	This requirement specifies that integral heated vaporizers must be located at least 100 feet from a property line that can be built upon and at least 50 feet from other select structures and equipment.
Process Equipment Spacing (section 2.2.6.1 of NFPA 59A)	This requirement specifies that process equipment containing LNG or flammable gases must be located at least 50 feet from sources of ignition, a property line that can be built upon, control rooms, offices, shops, and other occupied structures.
Marine Transfer Spacing (33 CFR 127.105)	This requirement specifies that each LNG unloading flange must be located at least 985 feet from any bridge crossing a navigable waterway.

The LNG storage tanks would use a full-containment design, consisting of an inner steel tank surrounded by a secondary outer concrete tank. The outer tank would be sized to contain 110 percent of the full design volume of the tank in the event that there is a complete failure of the inner tank. NorthernStar proposes to install an additional protective measure of a 5-foot-high, tertiary earthen berm around the LNG facility. The structure's volumetric capacity would contain a single LNG tank's maximum liquid capacity in the event of any hypothetical catastrophic event.

All LNG transfer lines would be provided with spill collection and containment troughs that would drain to either the wharf area containment basin or the tank area containment basin, each of which is equipped with a sump. Each sump would be sized to contain a 10-minute spill from one of the unloading lines at the maximum design transfer rate.

2.8.1.2 Hazard Detection System

A fire protection and gas detection system would be designed and installed at the LNG terminal in compliance with NFPA 59A, 33 CFR 127, and 49 CFR 193, as well as practices recommended by the ANSI and API. The design would take into consideration an evaluation based on sound fire protection engineering principles, analysis of local conditions, hazards within the facility, and exposure to or from other property.

2.8.1.3 Hazard Control System

Both passive and active measures for fire and hazard prevention or control would be incorporated into the design and construction of the LNG terminal. Passive measures would prevent or minimize a fire or hazard and would include spill impoundment systems, ignition source control, and fireproofing. Active control measures would be implemented in the event of a fire or the release of LNG and would include the following fire-fighting systems and equipment:

- a looped, underground fire suppression piping system that would use water from the Columbia River;
- 2 main firewater pumps located on the wharf;
- 16 fire hydrants;
- 14 fire hose reels within the administration/warehouse building and control building;
- 16 portable extinguishers for liquid, gas, or electrical fires; and
- 9 dry chemical extinguishers, 1 positioned on the wharf and 8 positioned on the LNG storage tanks.

2.8.1.4 Fail-Safe Shutdown

The proposed LNG terminal would have an ESD system that would isolate and shut off sources of combustible gas and automatically shut down process equipment. Three levels of shutdown would be configured for the LNG terminal facility. Level 1 would be used for a major incident and carry out a total plant shutdown. Level 2 ESD would only shut down the wharf unloading area, and Level 3 ESD would be used for shutting down individual pieces of equipment.

2.8.1.5 Security System

NorthernStar would develop a security plan for the LNG terminal that would be in accordance with 33 CFR 105 and 49 CFR 193. This plan would describe security inspections and patrols, liaisons with local law enforcement officials, design and construction of protective enclosures, lighting, monitoring, alternative power sources, and warning signs.

Security would be maintained for the entire site by personnel stationed 24 hours per day, 7 days per week. A security fence would be constructed around the LNG facilities at the terminal site, with controlled access to the entrance gate and at the wharf. A guardhouse post would be located at the entrance gate. The security fence would be chain-link material approximately 8 feet high with barbed wire at the top. The fence would be monitored by security cameras and motion detectors and would be patrolled throughout the day and night. Security lighting around the facility would be provided as required to comply with 49 CFR 193, Subpart J Security.

2.8.2 Pipeline and Associated Aboveground Facilities

The pipeline and aboveground facilities associated with the Bradwood Landing Project would be designed, constructed, operated, and maintained in accordance with the DOT's *Transportation of Natural and Other Gas By Pipeline: Minimum Federal Safety Standards* in 49 CFR 192. These safety standards are discussed in section 4.11.9.1.

2.8.2.1 Corrosion Protection and Detection System

The pipeline would be protected from corrosion by a fusion-bonded epoxy coating. A cathodic protection system would also be installed to prevent or minimize corrosion. The system reverses the natural current flow from the pipelines to the ground, which could result in corrosion at imperfections in the pipeline coating. The cathodic protection system would be monitored and inspected periodically in accordance with DOT requirements to ensure proper and adequate corrosion protection. The interior of the pipe would be periodically monitored for corrosion using internal in-line pigging technology.

2.8.2.2 Emergency Response Procedures

Pipeline system emergencies can include gas leaks, fire or explosion, and/or damage to the pipeline and aboveground facilities. In accordance with DOT regulations, NorthernStar would develop a pipeline emergency response plan to address procedures to be followed in the event of an emergency along the pipeline. This plan would include training of employees on emergency procedures; establishing liaisons with appropriate fire, police, and other community officials; and informing the public on how to identify and report an emergency condition along the pipeline route. This would be a separate plan from the ERP for the LNG terminal and waterway.

2.9 FUTURE PLANS AND ABANDONMENT

NorthernStar has not proposed any plans for expansion of the proposed LNG terminal or pipeline. However, if there is a future demand for additional natural gas in the market area, provisions have been made in the layout of the site to allow for a possible future expansion by adding a third LNG storage tank and associated equipment. This possible future expansion would increase the natural gas sendout capacity of the LNG terminal to 1.5 Bcfd. The proposed pipeline has already been sized for the maximum future capacity of 1.5 Bcfd; therefore, no other expansion of the pipeline facilities is planned at this time. Before any expansion of the proposed facilities, NorthernStar would be required to seek the appropriate authorization from the FERC. The FERC would conduct a separate environmental analysis under the NEPA before authorizing a proposed expansion of NorthernStar's facilities.

NorthernStar has no future plans to abandon or remove the proposed LNG terminal and pipeline facilities. Based on economic projections, the facilities are expected to have an operating life of 30 to 40 years. If market conditions persist, the facilities could be maintained to operate for 50 years or more. Any future abandonment would be subject to the appropriate environmental and non-environmental review based on federal, state, and local regulations in effect at that time.

NorthernStar has submitted a decommissioning plan to Clatsop County and the State of Oregon. The decommissioning plan specifies that NorthernStar would submit a proposed final retirement plan 2 years before closure of the LNG facility. The retirement plan would provide for completion of retirement within 2 years of the end of operations and describes how the site would be restored to a useful, nonhazardous condition. The decommissioning plan also provides for financial assurance for completion of retirement.

3.0 ALTERNATIVES

In considering NorthernStar's applications, the FERC will review both the environmental and non-environmental record in deciding whether it is in the public convenience and necessity to issue any authorization for the project. The EIS addresses alternatives to the proposed actions before the FERC, the COE, and the Coast Guard. The FERC must consider whether or not to approve the facilities proposed by NorthernStar.

The COE will review permit applications submitted by NorthernStar in October 2006 under section 10 of the RHA and section 404 of the CWA. The Coast Guard will consider issuing an LOR under its regulations at 33 CFR 127.009 regarding the suitability of the waterway for LNG marine traffic.

3.1 FERC ALTERNATIVES

In accordance with the NEPA and Commission policy, we have evaluated a number of alternatives to the Bradwood Landing Project to determine if any are reasonable and environmentally preferable to NorthernStar's proposed action. Alternatives considered by the FERC, described in more detail below, include no action or postponed action, system alternatives, LNG terminal site alternatives, LNG terminal layout alternatives, vaporization technologies, power line route alternatives, pipeline route alternatives, and dredging and dredged material placement alternatives.

Alternatives were evaluated against the objectives of the Bradwood Landing Project, as described in section 1.1. The primary objective of the project is to deliver competitively priced natural gas to meet the growing demands of gas consumers in the Pacific Northwest. To achieve this objective, NorthernStar would: 1) construct and operate an LNG import terminal with docking/unloading facilities capable of berthing one LNG carrier, an LNG storage capacity of 320,000 m³, and LNG vaporization facilities with a peak sendout capacity of 1.3 Bcfd; and 2) construct and operate a pipeline with a maximum capacity of 1.5 Bcfd. The sendout pipeline would serve the target market by delivering natural gas to the Georgia-Pacific paper mill at Wauna, Oregon and the PGE Beaver Power Plant at Port Westward, Oregon, interconnecting with Northwest Natural's existing bidirectional intrastate pipeline facilities capable of transporting gas to their Mist underground storage facility, and interconnecting with the Williams Northwest interstate pipeline system.

Specifically, at an average sendout rate of 1 Bcfd, the Bradwood landing Project is expected to deliver about 50 percent of its natural gas to Oregon consumers, 30 percent would go to Washington consumers, and less than 20 percent would go to Idaho, northern California, and Nevada combined. At an average sendout of 400 MMcfd, 73 percent of natural gas would go to end users in Oregon, 26 percent would go to Washington customers, and less than 1 percent would go to other states combined. To be considered as a reasonable alternative to the Bradwood Landing Project, a project should provide comparable volumes of natural gas to Oregon and Washington.

The FERC's evaluation criteria for selecting potentially reasonable and environmentally preferable alternatives include whether they:

- are technically feasible, reasonable, and practical;
- offer significant environmental advantage over the proposed project; and
- meet the objectives of the project, as described above.

With respect to the first criterion, it is important to recognize that not all conceivable alternatives are technically feasible and practical. Some alternatives may be impracticable because they are unavailable and/or incapable of being implemented after taking into consideration costs, existing

technologies, and logistics in light of the overall project purpose. In conducting a reasonable analysis, it is also important to consider the environmental advantages and disadvantages of the proposed action and to focus the analysis on those alternatives that may reduce impacts and/or offer a significant environmental advantage.

The Commission has three possible courses of action in processing NorthernStar's proposal. The Commission may: 1) deny the proposal, 2) postpone action pending further study, or 3) authorize the proposal with or without conditions. In arriving at a course of action, the Commission considers a range of alternatives in light of the project's objectives, evaluation criteria, and environmental comparisons. Each alternative is considered until it is clear that the alternative is not reasonable or would result in greater environmental impacts that could not be readily mitigated. Those alternatives that appear to be the most reasonable with less than or similar levels of environmental impact are reviewed in the greatest detail.

3.1.1 No Action or Postponed Action

If the Commission denies NorthernStar's proposal or postpones action on the proposal, the short- and long-term environmental impacts identified in this EIS would not occur. If the Commission selects the no action or postponed action alternative, the objectives of the proposed project would not be met and NorthernStar would not be able to import LNG to provide natural gas to markets in the Pacific Northwest. It is purely speculative to predict the resulting effects and actions that could be taken by other suppliers or users of natural gas in the region as well as any associated direct and indirect environmental impacts.

The States of Washington and Oregon do not produce much natural gas, and must import natural gas produced from the WCSB, the Rocky Mountains, and the San Juan Basin via the existing GTN and Williams Northwest interstate pipeline systems (see section 1.1). Various studies have indicated that under certain circumstances, existing gas supplies and infrastructure could fall short of meeting regional peak demand by 2012 (NWGA, 2007; ICF, 2007). Without the new source of natural gas to be provided through the LNG import terminal proposed by NorthernStar, customers in the Pacific Northwest would have fewer and potentially more expensive options for obtaining natural gas supplies in the near future.

In the State of Washington, the price of natural gas increased by as much as 300 percent over the last several years due to a number of factors, such as lack of investment in new infrastructure; growth in regional demand, including an increase in the use of natural gas for power generation; deregulation of state controls on electric generation; and limitations on natural gas supplies, especially the reduction of imports from Canada (WUTC, 2006). In Oregon, wholesale natural gas prices rose 168 percent between 1999 and 2004 (ODE, 2005a). Higher natural gas prices could adversely influence the regional economy by reducing realized household incomes and business profits (Greenspan, 2003). Oregonians spend about \$10 billion on energy, and in 2000, 1.2 percent of personal income in Oregon was spent on natural gas. Due to higher natural gas prices, wholesale electric costs rose sharply in Oregon between 2003 and 2005 (ODE, 2005a; 2008a). The U.S. Department of Commerce (2005) estimated that higher gas prices reduced growth of the Gross Domestic Product by about 0.2 percent between 2000 and 2001, and between 2000 and 2004 about 489,000 civilian jobs were lost to the national economy, including 79,000 in manufacturing industries, because of increases in the price of natural gas. The U.S. Department of Commerce (2006) also indicated that higher natural gas prices in the future would push up consumer prices and reduce real disposable income. A study sponsored by the Interstate Natural Gas Association of America (INGAA) Foundation in 2005 (INGAA, 2005) found that a delay of 3 years for installing new natural gas infrastructure, including LNG import terminals, in the Pacific Northwest would cost the Oregon economy an estimated \$11.1 billion and the Washington State economy about \$9.7 billion.

Higher natural gas prices (or the threat of higher gas prices) could also lead to alternative proposals to develop natural gas delivery infrastructure, increased efficiency and conservation or reduced use of natural gas, and/or the use of other sources of energy. Alternative fuel sources, such as coal or oil, could provide an equivalent amount of energy as the proposed Bradwood Landing Project, but may have greater environmental impacts; specifically with regard to air pollution and the release of greenhouse gases (GHG) (see section 3.1.1.3 and table 3.1.1-1). Currently, 30 percent of the natural gas imported into the Pacific Northwest is used for power generation (ICF, 2007). The EIA Annual Energy Outlook for 2008, Early Release Version (EIA, 2007d) projected an increase in total coal consumption in the United States between 2006 and 2030 as coal is used more in the future for electric generation, in part due to constraints on supplies of natural gas and higher natural gas prices. Higher natural gas prices were also cited as a reason for the projected increased demand for total renewable fuels. However, as discussed below in section 3.1.1.3, renewable energy sources, such as solar, wind, and geothermal resources, would not be able to produce an amount of energy equal to the proposed Bradwood Landing Project.

3.1.1.1 Alternative Natural Gas Infrastructure Proposals

The adoption of the no action alternative could result in the expansion of other existing interstate natural gas pipeline systems or LNG facilities to meet the increasing demand for natural gas in the Pacific Northwest. This might include constructing or expanding regional pipelines as well as LNG import and storage systems. In section 3.1.2 we examine system alternatives. Any expansion of existing systems or construction of new facilities would result in specific environmental impacts that could be less than, similar to, or greater than those associated with the Bradwood Landing Project.

3.1.1.2 Increased Efficiency and Conservation of Natural Gas

Denying or postponing a decision on NorthernStar's application could limit access to new supplies of natural gas in the future, which could in turn contribute to higher natural gas prices. Higher prices could potentially result in customers conserving or reducing the use of natural gas. There is no doubt that both conservation and increased efficiency have an important role to play in the future energy needs of the Pacific Northwest. Between 1990 and 2002, utilities in the Pacific Northwest invested \$2.4 billion in conservation, resulting in savings of 2,600 average MW per year (ODE, 2005a). In its Fifth Power Plan (Northwest Power and Conservation Council, 2005), the Northwest Power and Conservation Council (which covers Oregon, Washington, Idaho, and Montana) recommended conservation targets of 700 average MW between 2005 and 2009 and 2,500 average MW during the 20-year planning period.

The State of Oregon offers both Business and Residential Energy Tax Credits and an Energy Loan Program designed to help businesses and residential consumers invest in energy efficiency through such actions as the purchase of more efficient appliances, heating and air conditioning systems, and building renovations. These programs have seen dramatic results in the last 5 years. According to the 2005-2007 Oregon Biennial Energy Plan (ODE, 2005a), in 2000 the combined residential and business energy tax credit programs stimulated savings of 58.9 kilowatt-hours (kWh). By 2003, savings had reached 860.3 million kWh. In 2005, the Business Energy Tax Credit resulted in savings of 2.2 billion kWh in electricity and 107.9 million therms in natural gas, while the Residential Energy Tax Credit saved 104.1 million kWh in electricity and 2.8 million therms in natural gas total in Oregon (ODE, 2008a).

It is important to recognize that projections for energy demand in the region incorporate the savings achieved and anticipated from planned energy conservation measures. While it is possible that continued high natural gas and electricity prices may result in some increase in the rate of conservation, the incremental increase will not have a material effect on the regional demand for new sources of natural gas supply. Additional regional natural gas supplies are needed to compensate for declining United States production and Canadian imports as well as the increasing regional demand from economic growth.

Furthermore, energy conservation is not, in itself, an energy source and cannot ultimately replace the natural gas needed by end users such as industrial and residential customers (see section 1.1). Therefore, increased conservation does not provide an alternative to the proposed project, but rather a complementary component of the overall energy demand and supply mix.

3.1.1.3 Other Sources of Energy

It is also conceivable that adoption of the no action alternative could promote the development of other (non-LNG/non-natural gas) sources of energy. In order to assess the alternative fuels and energy sources that would potentially be available to replace the needed natural gas supplies to be provided by the proposed project, it is necessary to understand how natural gas is used by consumers in Oregon. In 2003, 18 percent of the energy used in Oregon came from natural gas. About 10 percent of the electricity generated for Oregon was fueled by natural gas in 2005 (ODE, 2008a). According to the 2003 Oregon Energy Plan (ODE, 2003), excluding natural gas used for electrical generation, the industrial sector is the primary consumer of natural gas, using more than both the residential and commercial sectors combined. Natural gas accounts for approximately 30 percent of total industrial sector energy use. The primary use of natural gas in the industrial sector is for process heating. During the 1990s, industries shifted to natural gas from wood, heating oil, and electricity. Therefore, in the absence of increasing supplies of competitively-priced natural gas, the industrial sector would likely need to return to these alternative sources to meet demands for energy supplies in the future. However, this may not be possible for all users, as the shift to natural gas in many cases may have required changes in equipment. In these cases, the economic implications of reverting to alternate energy sources may be too great and the users may have no choice but to curtail production.

Commercial and residential use of natural gas is primarily for space and water heating. Again, the shift to natural gas in both the commercial and residential sectors during the 1990s to meet space and water heating demands has meant a shift away from the use of wood, heating oil, and electricity (ODE, 2003). Therefore, in the absence of increasing supplies of competitively-priced natural gas, the commercial and residential sectors would likely return to these alternative sources to meet demands for energy in the future.

For all sectors, the recent shift to the use of natural gas in place of wood, oil, and electricity has led to significant environmental benefits for Oregon and the Pacific Northwest. It is widely recognized that natural gas is the fuel of choice with respect to air emissions. The Oregon Energy Plan notes that energy use and production have significant impacts on the environment, in particular on air and water resources. With respect to air emissions, the same document notes that natural gas as a fuel for generating electricity produces significantly less CO₂ and nitrogen oxides (NO_x) than existing coal-fired power plants, and virtually no volatile hydrocarbons, sulfur oxides (SO_x) or particulate matter. Coal-fired power plants produced 41 percent of Oregon's 2005 fuel mix for generating electricity. In a May 2008 report to the Governor of Oregon, the ODE stated: "as climate change legislation is enacted, it is likely that financial conditions will encourage the switch from coal to natural gas since natural gas has much lower life-cycle GHG emissions. It is unlikely that Oregon will be able to replace all of the coal-fired power it uses with renewables in the short-term, so natural gas consumption is likely to rise" (ODE, 2008b). When used directly for space and process heating by consumers, natural gas is also cleaner in air emissions than wood or heating oil. As an alternate to hydropower, which accounted for delivery of approximately 42 percent of Oregon's power generation supply in 2005 (ODE, 2008a), natural gas avoids the impacts on endangered salmonids and their habitats in the Pacific Northwest associated with hydropower dams.

As noted above, in the absence of additional supplies of natural gas to meet increasing consumer demand, users would be forced to seek alternate fuels and energy sources. To the extent that users

returned to the use of traditional fuels (wood, oil, coal) this shift would result in increased environmental impacts compared to the use of the natural gas that would be provided by the proposed project. With respect to the potential increased demand for electricity as an alternate energy source, the environmental implications are somewhat more difficult to define as discussed below.

As indicated in the Oregon Energy Plan, the state's electric generation fuel mix varies with weather, specifically water and snow conditions, which dictate the availability of hydropower. For example, in 2003, natural gas generation accounted for approximately 7 percent of total generation, whereas in 2001, it was approximately 15 percent (ODE, 2008a). This demonstrates the response of the generation system to variations in availability of supply sources as well as demand. As a result of the recent development of new gas-fired generation in the region in response to the electricity crisis of 2000-2001, sufficient generation capacity is available to meet increases in demand in the region in the foreseeable future. However, the bulk of this new generation is gas-fired and, as a result, highly vulnerable to the volatile price fluctuations of recent years. Between 2000 and 2005, electricity rates in Oregon rose 28 percent, in part because of higher natural gas prices. Thus, to the extent that consumers revert to electricity in the absence of increased availability of competitively-priced natural gas, it is likely that a significant portion of that electricity will come from existing coal-fired generation sources during non-peak periods, resulting in greater environmental impacts than the proposed project.

Renewable Energy

Renewable energy resources represent an alternative to the use of natural gas depending on the types of resources and their uses. For example, hydro and wind power resources represent alternatives for electricity generation, whereas biomass, solar, and geothermal resources can be used to generate heat as well as electricity. However, there are also environmental impacts associated with some types of renewable resources. For example, hydropower dams may affect fish, and wind turbines may affect birds and bats.

The Pacific Northwest has been at the forefront nationally in terms of the use of renewable energy resources, in large part due to the historic prevalence of hydropower resources in the region. Approximately 11 percent of total energy use in Oregon in 2003 was supplied by renewable resources (ODE, 2008a). In 2007, the Oregon legislature created a state Renewable Portfolio Standard. This requires all electric utilities that serve Oregon to include power generated from renewable sources in their energy mix by 2025, with a sliding scale of percentages over time.

Hydropower and Wave Energy

Hydropower, or generating electricity from water stored behind dams and then run through turbines, plays a significant role in the current energy mix of the Pacific Northwest, accounting for 64 percent of the region's energy capacity in 2006 (Northwest Power and Conservation Council, 2006). In 2007, hydropower generated 66,700 thousand MW hours in Washington State (EIA, 2007e). In Oregon, in 2005, hydropower produced 42 percent of the electricity in the state (ODE, 2008a).

However, the ODE recognizes that climate change may alter the runoff regime feeding water to the hydroelectric dams along the upper Columbia River, resulting in less summer power in the future. Legal issues concerning the operation of the dams with regards to fisheries could also diminish hydropower generation (ODE, 2008b).

New large hydropower projects are unlikely to play a role in renewable energy growth in the future. The ODE anticipates that the future of hydropower in Oregon would be dependent on developing small-scale micro-hydro or seasonal hydro projects, such as piped irrigation systems, or using run-of-the-

river technology which does not need water stored behind dams. Several new hydro projects, ranging from 1 MW to 12 MW, are currently in the planning stages in Oregon (ODE, 2008a).

According to the Northwest Power and Conservation Council (2007), most feasible hydroelectric facilities have already been developed. It is unlikely that new dams would be constructed in the future because of high development costs, environmental impacts, and the complex and lengthy licensing process. In fact, efforts are underway to remove some existing dams to restore habitat. Further, environmental scrutiny during the relicensing process for existing dams has, in some instances, resulted in increased release of water for fisheries, which has reduced their electric generation capacity. It has been estimated that hydropower generation is going to decline from supplying about 10 percent of the nation's electricity in 2005 to about 6 percent in 2020 (DOE, 2005). Thus, the development of additional hydropower resources is not considered to be a reasonable or environmentally preferable alternative to the proposed project.

A new potential source of electric power for the future is hydrokinetic energy, or electricity generated from ocean currents, swells, waves, or tidal action. These facilities could only be developed offshore. Currently, the United Kingdom has an ocean energy program supported by the government. The FERC recently initiated a licensing process for hydrokinetic test projects in the United States. The goal of the FERC pilot process is to allow developers to test new technologies, to determine the best location for hydrokinetic facilities, and to determine the environmental effects associated with the siting and operation of such facilities. It has been estimated that if hydrokinetic technologies could be successfully developed, it could potentially double the amount of hydrogenerated electricity available in the United States (FERC, 2007). The ODE (2008a) estimated that ocean wave energy could provide over 500 MW in electricity from Oregon projects developed over the next 10 years.

Although numerous preliminary permits have been issued on the east coast, only two wave power projects have been licensed under the FERC pilot program. Both are proposals from Finavera Renewables Ocean Energy, Ltd. (Finavera). One proposal calls for the installation of four 250 kW wave energy conversion buoys in Makah Bay off the coast of Washington State. The other Finavera project would be located off the coast of Humboldt County, California (Irish Independent, 2008). Additional wave power projects are in the early development stage for facilities near Grays Harbor, Washington and Reedsport and Coos Bay, Oregon (International Water Power and Dam Construction, 2008; Coos Bay World, 2008; KCBY, 2008). A report by the Electric Power Research Institute identified seven sites along the Oregon Coast as being potentially suitable for wave energy projects. In July 2006, Ocean Power Technologies proposed a 50 MW wave-power project in Oregon. The ODE counted eight applications for wave energy projects to the FERC proposed by developers or Oregon coastal counties (ODE, 2008a). In March 2008, the FERC signed a memorandum of understanding with the State of Oregon to coordinate procedures and schedules for the review of wave energy projects in state waters off the coast of Oregon (Electric Light & Power Utility, 2008; Dam Engineering, 2008).

There are no existing hydrokinetic facilities currently operating in the United States. The development of such resources in the future is speculative, because of challenges related to the use of new technologies, financial barriers, and an unclear regulatory process. Nor do we know about the potential environmental impacts resulting from the construction and operation of a hydrokinetic facility, although it appears that such a facility would likely have some effects on aquatic resources. Therefore, we do not consider hydrokinetic facilities to be a reasonable, feasible, or foreseeable alternative to the proposed Bradwood Landing Project in the near future.

Geothermal

Geothermal resources are naturally occurring sources of heat, such as hot springs, geysers, or volcanoes that could be tapped to generate energy. Geothermal resources include high-temperature (above 100 °C) sources for electric generation, intermediate temperature (50 to 100 °C) sources for industrial, agricultural, and municipal uses, and low temperature sources for residential heat pump uses. In 2005, wind and geothermal resources combined supplied 1 percent of the electric generation in Oregon, averaging 53 MW (ODE, 2008a, 2008c). Geothermal resources in Oregon are used to supply heat for buildings, swimming pools, and industrial uses. As of 2005, there were about 2,200 ground-source heat pumps providing space and water heating to homes in Oregon. The City of Klamath Falls uses geothermal energy for a district heating system. There have been explorations on the flanks of Newberry Volcano to evaluate its potential future use for high-temperature geothermal electricity production (ODE, 2008a). The Warm Springs Tribes are considering a geothermal project at Mount Jefferson. The 13-MW Raft River Project in southern Idaho is the only commercial geothermal power plant operating in the Pacific Northwest (Northwest Power and Conservation Council, 2007).

The main barriers to the further development of geothermal resources are the identification of potential naturally occurring sources, and above-market costs. Given the physical limits of geothermal sites that have a potential for future exploitation, the lack of interest from investors in developing new potential resources, and the minimal energy that geothermal resources produce, we do not see this type of renewable resource as a feasible or predictable alternative to the proposed Bradwood Landing Project.

Biomass and Biogas

Biomass resources can produce electricity and heat or steam from wood, wood waste, plant and animal waste, or other organic matter. As of 2007, biomass generation represented about 2 percent (900 MW) of the total electric power capacity of the Pacific Northwest (Northwest Power and Conservation Council, 2007). In 2004, biomass produced 79 trillion Btu of energy in Oregon, or about 6 percent of that state's total energy supply (ODE, 2008a).

More than 90 percent of Oregon's biomass energy comes from forest or wood waste and paper mill pulping liquor. About 40 percent of Oregon's biomass energy comes from wood waste burned at 49 industrial sites. Ten of these sites produced 866,000 MW-hours of electricity. About 46 percent of the total biomass energy in Oregon is produced from combustion of pulping liquids at six mills. Two mills produced about 310,000 MW-hours of electricity in 2004 (ODE, 2008a). A new 10-MW wood waste cogeneration plant recently went on line at the end of 2007 in Lyons, Oregon (Northwest Power and Conservation Council, 2008).

There are three landfills in Oregon that tap waste methane gas to generate 37,000 MW-hours of electricity for industrial use, with a fourth under construction in southern Oregon. In addition, 29 wastewater treatment plants in Oregon use methane to generate 26,000 MW-hours of electricity to provide heat for sewage treatment. Two facilities produced about 500 MW-hours of electricity from cow manure (ODE, 2008a).

Barriers to the further development of biomass resources include uncertainty in biomass outputs, the high costs associated with the transporting of forest products to an energy conversion facility, and lack of private capital investment in the development of additional biomass facilities. In Oregon, virtually every paper mill has already installed equipment to allow the utilization of biomass waste, leaving little potential to develop new resources. Because of the relatively high costs of development, only about 15 MW in new biomass generation were brought on line between 2004 and 2007 in the Pacific Northwest (Northwest Power and Conservation Council, 2007). Because of the difficulties of developing biomass

resources, and the small amount of additional energy they could produce, biomass does not represent a feasible, reasonable, and foreseeable alternative to the proposed Bradwood Landing Project.

Solar

There are three primary ways to harvest solar energy: 1) direct sunlight into buildings can be used for light and heat; 2) roof-mounted collectors can use sunlight to heat water; and 3) sunlight can be converted into electricity using photovoltaics or solar panels. There are about 300 solar electric systems in the State of Oregon, and residents have installed more than 17,600 solar water heating systems in the last 25 years (ODE, 2008a).

There is the potential to develop solar energy in sunny areas, such as eastern and southern Oregon. For example, a project in Bend, Oregon is installing 900 solar modules, with assistance of a loan from the ODE. In 2006, the Jackson County Fairgrounds dedicated a solar pavilion which generated about 24 kW, or enough electricity for three homes (ODE, 2008a).

However, solar power has never made a significant contribution to the energy mix in the Pacific Northwest because of cloudy weather conditions at major metropolitan population centers along the coast. There is not enough sunlight to generate much solar energy during the cloudy winter months when there is peak demand in Portland and Seattle. National Weather Service data collected at the Seattle-Tacoma International Airport, which has a similar climate to much of western Oregon, showed the average annual possible sunshine for the area is about 47 percent. Data presented by the Renewable Energy Power Project indicated that the daily average is 2.9 kWh per square meter (m²) for Seattle. At this rate, thousands of acres of solar collectors would be needed. Solar power does not appear capable of producing enough energy in this region to be considered a reasonable or feasible alternative to the proposed Bradwood Landing Project.

Wind

In the Pacific Northwest, wind power accounts for about 3 percent of the regional capacity, or 1,730 MW total (Northwest Power and Conservation Council, 2007). Oregon has wind projects in operation with a total capacity of 450 MW (ODE, 2008a). In Washington and Oregon, combined, about 885 MW of additional capacity would be made available from new wind farms that recently went into service in 2007 or are presently under construction (Northwest Power and Conservation Council, 2008).

Due to the variable nature of wind, on average, wind turbines only generate about one third of their maximum output capacity. Another barrier to the further development of wind farms in eastern Oregon is lack of transmission capacity. Clustering effects at wind farms result in spikes and troughs in production that have no relation to demand, and contribute to transmission congestion. However, a stakeholder group evaluating this situation in 2006 believes that about 6,000 MW of electricity from eastern Oregon wind projects could find its way into the region's grid by 2024 (ODE, 2008a). In addition, the cost of developing new wind projects has gone up since 2004 because of rising prices for equipment (Northwest Power and Conservation Council, 2007). Environmental consequences from wind farms include visual effects and impacts on birds and bat populations.

Lastly, there are limitations to wind power in comparison to energy production from the proposed project. The entire inventory of existing and proposed wind projects in Oregon would only equal about 4.3 percent of the energy sendout capacity of the Bradwood Landing Project. Taking the largest wind turbine made by General Electric, and assuming that the wind blows constantly so that full output is achieved, it would take 34,000 wind turbines to produce an equivalent amount of electricity that could be

generated using the total capacity of the natural gas from the Bradwood Landing Project. Therefore, wind power does not represent a reasonable, feasible, and foreseeable alternative to the proposed project.

Nuclear Energy

Nuclear power has the potential to generate enough energy to substitute for the proposed Bradwood Landing Project. However, due to economic, environmental, and regulatory factors, the future of nuclear power as an energy alternative is in doubt. There are currently 103 nuclear reactors operating at 65 sites in 31 states, generating about 19 percent of the nation's electricity. There is only one nuclear power plant currently operating in the Pacific Northwest; the Columbia Generating Station, located north of Richland, Washington, with an electrical output of 1,107 MW. Imported power generated from nuclear sources represented about 3 percent of the electricity mix in Oregon in 2005 (ODE, 2008a).

The only nuclear power facility in Oregon, the Trojan plant on the Columbia River in Columbia County, operated between 1976 and 1992. It was closed in 1993, years before its scheduled operational life-span, in part because of environmental and safety issues. The Hanford nuclear weapons plant in southeast Washington halted production in 1988, but is the site of radioactive contamination that will take years and billions of dollars to remediate (ODE, 2008a).

Until recently, no new nuclear power plants have been planned since the mid-1980s due to concerns raised after the Three Mile Island incident in Pennsylvania in 1979. As a result of incentives offered in the EPAct, the Nuclear Regulatory Commission expects that it may receive up to 21 new applications for nuclear power plants between 2007 and 2009. Two of these proposed plants would be located in Idaho; one at Bruneau and one near Boise. The Northwest Power and Conservation Council believes that the earliest a new nuclear power plant could come on line in the Pacific Northwest would be 2015.

We do not consider nuclear power to be a feasible foreseeable alternative to the proposed project. Barriers to the nuclear industry include problems related to the disposition of spent fuel, long regulatory review time, and costs. The Watts Bar nuclear power plant in Tennessee that began operation in 1996 took 23 years to complete, at a cost of \$6.9 billion. The proposed nuclear power plant at Bruneau, Idaho is estimated to cost \$4.5 billion to build (Idaho Statesman, 2008). The ODE (2008a) has stated that "nuclear plants are not likely to be approved in Oregon in the near term." An Oregon law requires voter approval to allow a new nuclear power plant to be built in the state, and only if a permanent repository can be found for the disposal of plant waste.

Other Fossil Fuels

As indicated above, compared to other fossil fuels such as coal or oil, natural gas is a relatively clean and efficient fuel that can reduce the emission of regulated pollutants (e.g., NO_x, sulfur dioxide (SO₂), and particulate matter) or unregulated greenhouse gases (e.g., CO₂). Given there are emissions associated with producing, processing, transmitting, and distributing natural gas and other fossil fuels, it is difficult to accurately quantify the impact of an LNG import project on air quality. However, credible estimates of air emissions can be developed based on reasonable assumptions regarding burning natural gas delivered by the project compared to burning fossil fuels that would likely be utilized if the gas from the project was not available. Table 3.1.1-1 lists the emissions that would result from the Bradwood Landing Project assuming it provides about 1.3 Bcfd of natural gas to the Pacific Northwest market and the corresponding emissions that would result if an equivalent amount of energy were generated using coal or fuel oil in lieu of natural gas. It is clear from the table that the use of either fuel oil or coal would increase emissions significantly. Additionally, to comply with current air emission regulations, emission control technologies could be required that could limit the economic viability of any new oil- or coal-fired facility.

TABLE 3.1.1-1					
Comparison of Air Emissions from Burning Fossil Fuels ^a					
Fossil Fuel	SO ₂ (tpy)	NO _x (tpy)	PM ₁₀ (tpy)	CO ₂ (tpy)	C (tpy)
Natural Gas	143	21,522	1,723	23,833,333	6,500,000
Fuel Oil	112,636	43,047	2,441	34,558,333	9,425,000
Coal	301,321	150,661	6,673	45,283,333	12,350,000
^a	The emissions generated by coal, fuel oil, and natural gas were estimated using the most recent Best Available Control Technology (BACT) analyses identified on the EPA Reasonably Available Control Technology/BACT/Lowest Achievable Emission Rate Clearinghouse for boilers with heat input ratings between 100 and 250 million Btu per hour. The emissions from each fuel source are estimated based on a fuel use of 1.3 Bcfd, 365 days per year, 1,000 Btu/cubic foot.				
PM ₁₀	particulate matter less than 10 microns in diameter				
C	carbon				
tpy	tons per year				

In addition to the increased emissions associated with the burning of coal or fuel oil, each of these fuels would also have to be imported into the project area and stored, similar to the proposed LNG. The distribution of these fuels to market would require more truck, barge, and train trips than the distribution of an equivalent amount of energy derived from natural gas, which would increase emissions and traffic congestion.

The ODE conducted an independent review of life-cycle GHG emissions resulting from LNG projects, making assumptions from the point of origin to its use for electric generation in Oregon. The ODE concluded that carbon emissions from vaporized LNG when combusted in a conventional electric power plant would fall somewhere between domestically produced natural gas transported by interstate pipeline and coal. However, the ODE study added on emissions produced by long distance shipping of the LNG from foreign counties, including the fuel used by LNG carriers in transport, and in the liquefaction and regasification processes. According to the ODE review, when combusted in a conventional electric power plant, life-cycle GHG emissions from LNG were forecast to be 6 to 12 percent greater than domestically produced natural gas transported by interstate pipelines, but 39 to 48 percent less than coal (ODE, 2008b).

3.1.2 System Alternatives

System alternatives are options that would make use of other existing LNG or natural gas facilities to meet the stated objectives of the proposed project. A system alternative would make it unnecessary to construct all or part of the proposed project even if some modifications or additions to the existing facilities are necessary. These modifications or additions would result in environmental impacts that could be less than, similar to, or greater than those associated with construction of the proposed project. Ultimately, the purpose of identifying and evaluating system alternatives is to determine whether potential environmental impacts associated with construction and operation of the Bradwood Landing Project could be avoided or reduced by using another system.

3.1.2.1 Existing Pipeline Systems

The Pacific Northwest receives Canadian natural gas produced in British Columbia and Alberta and domestic gas from sources in the Rocky Mountain region and San Juan Basin. Two existing interstate natural gas pipelines, the Williams Northwest pipeline system and TransCanada's GTN pipeline system, currently serve the Pacific Northwest (see figure 3.1.2-1). These interstate pipelines connect to various LDCs in the Pacific Northwest, including Northwest Natural, Avista Corporation, and Cascade Natural Gas.

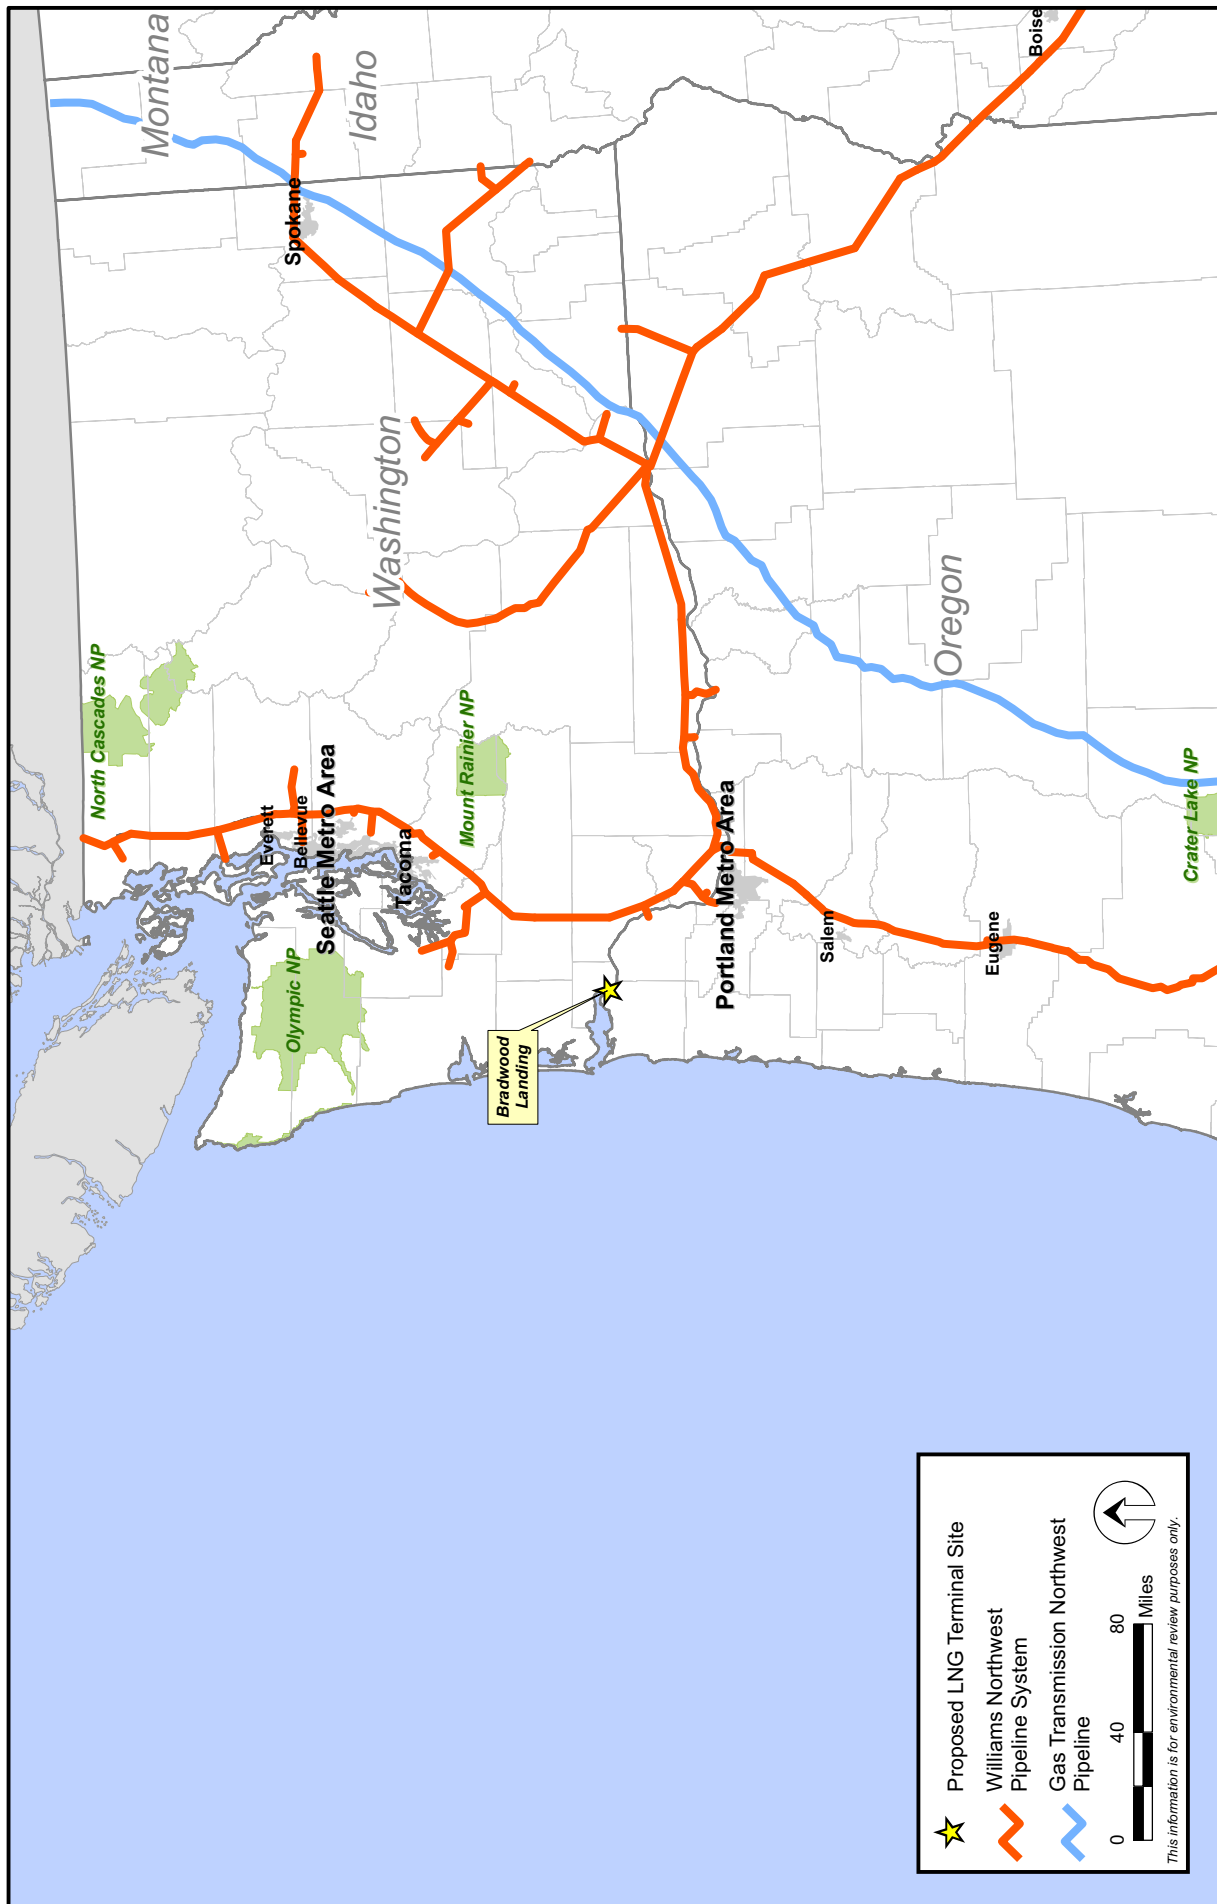

Figure 3.1.2-1
Bradwood Landing Project
 Existing Interstate Pipelines in Pacific Northwest

Williams Northwest pipeline is a 3,900-mile-long bi-directional transmission system crossing the States of Washington, Oregon, Idaho, Wyoming, Utah, and Colorado. This system provides access to British Columbia, Alberta, Rocky Mountain, and San Juan Basin natural gas supplies (Williams, 2007). The Williams Northwest system can receive up to about 1.3 Bcfd from its interconnection with Westcoast Energy at Sumas, Washington. Its mainline pipeline coming from the north to Vancouver, Washington has a capacity of 630 MMcfd. Coming west into Oregon from Caldwell, Idaho the system has a capacity of about 480 MMcfd. Between its interconnection with GTN near Stanfield, Oregon and Vancouver, Washington the system has a capacity of 550 MMcfd (ICF, 2007).

The GTN pipeline system includes 612 miles of pipeline beginning at the Idaho/British Columbia border, traversing through northern Idaho, southeastern Washington and central Oregon, and terminating at the Oregon/California border. The GTN system interconnects with TransCanada's British Columbia system at Kingsgate, British Columbia; with the Williams Northwest system at Spokane and Palouse, Washington and Stanfield, Oregon; and with the Pacific Gas and Electric (PG&E) and Tuscarora systems near Malin at the Oregon/California border. The GTN system can transport more than 2.9 Bcfd, with about 1.0 Bcfd targeted for markets in the Pacific Northwest (GTN, 2008). Natural gas for the GTN pipeline originates primarily from supplies in the WCSB, although it can also receive Rocky Mountain gas from its interconnections with Williams Northwest.

As an alternative to developing a new LNG import terminal in the Pacific Northwest, we considered the possibilities of expanding or modifying the existing interstate natural gas pipeline systems operated by Williams Northwest or GTN. GTN, in partnership with Northwest Natural, is proposing an expansion, known as the Palomar Pipeline Project, extending from its existing mainline near Madris, Oregon, to an interconnection with Williams Northwest near Molalla, Oregon, then on to an interconnection with Northwest Natural's existing system to the Mist storage field, and a potential interconnection with the Bradwood Landing pipeline in Clatsop County, Oregon. Williams (the parent of Williams Northwest), in partnership with TransCanada (GTN's parent company) recently announced plans to develop the so-called Sunstone Project, that would consist of a new pipeline parallel to its existing mainline system between Opal, Wyoming and Stanfield, Oregon. Williams would then develop the Blue Bridge Pipeline Project, to connect to Seattle, Washington, in partnership with Puget Sound Energy, Inc. (PSE). These proposed expansions are discussed below under Newly Proposed Pipelines as System Alternatives in section 3.1.2.2.

The environmental impacts associated with the expansion or modification of an existing pipeline system to be able to deliver volumes of natural gas to the Pacific Northwest equivalent to the Bradwood Landing Project would depend on the project size, length, and design. Such a project would result in impacts on water resources, upland vegetation, wetlands, wildlife habitats, land use, and air quality that may be less than, equal to, or greater than the proposed Bradwood Landing Project.

One of the obstacles associated with the expansion of existing interstate pipeline systems as alternatives to the Bradwood Landing Project, would be the procurement of new sources of natural gas that those systems could transport, in addition to the volumes they currently carry, as opposed to the importation of LNG. Net natural gas imports from Canada are projected to decrease from 3.3 Tcf in 2005 to 1.2 Tcf in 2030 (EIA, 2007a).

The Rocky Mountain region is expected to increase its production of natural gas over the next 20 years, primarily from unconventional sources such as tight sands, shale, and coalbed methane. The portion of natural gas contributed by the Rocky Mountain region to the total of the lower 48 states' onshore natural gas production is expected to increase from 27 percent (in 2003) to 38 percent in 2025 (EIA, 2005a). Part of this predicted gain in share of total onshore production is because some other domestic regions are expected to experience declining production rates.

However, much of the additional new production in the Rocky Mountain region is targeted for markets in the Midwest and eastern United States. For example, the western phase of REX, authorized in FERC Docket No. CP06-354-000, consists of about 718 miles of 42-inch-diameter pipeline from Colorado to Missouri that went into service in early 2008. In April 2008, the FERC issued a final EIS for the eastern phase of REX, in Docket No. CP07-208-000, analyzing the potential environmental impacts of extending the pipeline an additional 639 miles from Missouri to Ohio. Alliance Pipeline, Inc., in partnership with Questar Overthrust Pipeline, recently announced plans to develop the proposed Rockies Alliance Pipeline Project, which would extend an 800-mile-long 42-inch-diameter pipeline from Wamsutter, Wyoming to Emerson, Minnesota (Natural Gas Intelligence, 2008c). In response, TransCanada announced plans for a 500-mile-long, 42-inch-diameter pipeline from Wamsutter, Wyoming to interconnect to the existing Northern Border system (Natural Gas Intelligence, 2008d).

There are also plans for new pipelines to bring Rocky Mountain gas to southern Oregon, northern Nevada, and northern California. Both the Bronco and Ruby projects propose to construct pipelines between the hub at Opal, Wyoming to interconnections with the existing GTN, Tuscarora, and PG&E systems just east of Malin, Oregon. The Ruby and Bronco projects are discussed under Newly Proposed Pipelines as System Alternatives in section 3.1.2.2.

3.1.2.2 Newly Proposed Pipelines as System Alternatives

We considered four newly proposed jurisdictional interstate pipeline projects as system alternatives to the Bradwood Landing Project. These projects are in different stages of development and review, as discussed below. The Palomar Pipeline Project, which is currently being reviewed under the FERC's Pre-filing process, proposes to transport Canadian and Rocky Mountain gas to the Portland metropolitan area. The Ruby Project and Bronco Pipeline Projects would both transport Rocky Mountain gas to the Oregon/California border. While the Ruby Project is currently being reviewed by the FERC under our Pre-filing process, the Bronco project has not yet come before the FERC. The potential Sunstone and Blue Bridge projects would increase the amount of Rocky Mountain natural gas that could be transported on the Williams Northwest system from Wyoming to Oregon and Washington. However, Williams has not yet come to the FERC with either the Sunstone or Blue Bridge project.

Palomar

On August 30, 2007, the FERC accepted a request from Palomar Gas Transmission, LLC (Palomar), to initiate the Pre-filing environmental review process for its proposed new pipeline project in Oregon, in Docket No. PF07-13-000. We issued an NOI to produce an EIS for the Palomar Project on October 29, 2007. The FERC intends to do an independent environmental review of the Palomar Project. However, we will further address the Palomar Project under the cumulative impacts section of this EIS, because it is a foreseeable future project that may be developed during the same time frame as the Bradwood Landing Project in the general geographic vicinity.

Palomar is a partnership between TransCanada's GTN and Northwest Natural. The main purpose of the Palomar pipeline is to bring Canadian and Rocky Mountain gas to the Portland, Oregon metropolitan area and the Willamette Valley, and compete with the Williams Northwest system, which currently is the only interstate pipeline having direct interconnections with Northwest Natural, the LDC for northwestern Oregon and southwestern Washington. In addition, a segment of the Palomar pipeline would interconnect with the proposed Bradwood Landing LNG terminal near Wauna, Oregon, and provide a second sendout pipeline that could bring new supplies of natural gas from imported LNG to the Portland metropolitan area and to the GTN mainline. The proposed Palomar pipeline would not be a replacement for the proposed Bradwood Landing sendout pipeline; but can be viewed as a newly proposed system alternative.

The Palomar Project has no clear environmental advantages over the Bradwood Landing Project. The Palomar Project would include about 215 miles of 36-inch-diameter pipeline, with a bi-directional flow capable of handling up to 1.4 Bcfd of natural gas. The pipeline would begin at an interconnection with GTN northwest of Madras, and extend over portions of Wasco, Clackamas, Marion, Yamhill, Washington, Columbia, and Clatsop Counties, Oregon. Palomar envisions the construction of the pipeline in two segments. The first segment would be about 109 miles long from the point of origin with GTN to an interconnection with Williams Northwest near Molalla, Oregon. A short lateral would provide an interconnection with Northwest Natural, also near Molalla. The second segment would be about 103 miles long between Molalla and Wauna, Oregon. If the Bradwood Landing Project is not authorized, or not built, Palomar would terminate its pipeline somewhere west of Molalla, at an as yet undetermined point of interconnection with Northwest Natural. Northwest Natural could then construct an expansion of its nonjurisdictional local distribution system to indirectly connect Palomar to its Mist storage field in Columbia County, Oregon.

The Palomar pipeline would be collocated adjacent to existing power lines or road rights-of-way for about 26 percent of its route. For a total of about 49 miles, the pipeline would cross federal lands, including parcels administered by the Prineville and Salem Districts of the U.S. Department of the Interior, Bureau of Land Management (BLM), and the Mount Hood National Forest. The route would cross two federally designated Wild and Scenic Rivers: the Deschutes and the Clackamas. Other special management areas crossed include the Tillamook and Clatsop State Forests, and the White River State Game Management Area.

We consider the Palomar Project to be a separate undertaking from the Bradwood Landing Project. Neither project is inter-dependent on the other. If Palomar is not authorized or built, the Bradwood Landing Project could still go forward, and visa versa. The two projects can be considered as competitors to supply natural gas from different sources to the same market. While NorthernStar proposes to import LNG from foreign countries to provide a new source of natural gas for the Pacific Northwest, Palomar proposes to transport Canadian and Rocky Mountain produced natural gas for the Portland metropolitan area and Willamette Valley.

Ruby

The FERC accepted the Ruby Project for Pre-filing review on January 31, 2008 in Docket No. PF08-9-000. On March 28, 2008, we issued a Notice of Pre-filing Environmental Review for the Ruby Project, and scheduled public scoping meetings at multiple locations in Wyoming, Utah, Nevada, and Oregon to take place in April 2008. We intend to produce an independent, stand-alone environmental document for the Ruby Project to comply with the NEPA. The U.S. Department of Agriculture, Forest Service (USFS), and BLM are participating as cooperating agencies in the production of the environmental document for the Ruby Project, as about 60 percent of the proposed route for pipeline would cross federally administered lands.

The Ruby Project was originally planned to be a joint venture between El Paso, Bear Stearns, and PG&E. Bear Stearns has recently undergone financial problems, and in early May 2008, PG&E announced it was pulling out of an agreement to acquire a 25.5 percent equity interest in the project, citing rising steel prices contributing to higher-than-expected pipeline costs. However, PG&E will remain as the anchor shipper for the Ruby pipeline, contracted for 375,000 Dt/d for 15 years (Energy Daily, 2008; Inside FERC, 2008c).

The purpose of the project is to bring Rocky Mountain natural gas to customers on the West Coast and Nevada. The project would consist of about 655 miles of 42-inch-diameter pipeline, extending from Opal, Wyoming to Malin, Oregon, with a capacity to transport about 1.2 Bcfd of natural gas. In

addition, there would be two compressor stations (one in Lincoln County, Wyoming and another in Elko County, Nevada), 10 interconnections at five measurement stations, and 40 mainline block valves.

The Ruby Project would have no clear environmental advantages over the Bradwood Landing Project. The Ruby pipeline would be about 18 times longer than the proposed Bradwood Landing sendout pipeline. The Ruby Project would affect about 12,000 acres total during construction, and 3,765 acres would become part of the permanent operational easement for the pipeline. This compares to about 700 acres affected by construction of the Bradwood Landing Project, with 350 acres becoming part of the permanent operational right-of-way. A total of about 63,262 horsepower would be required at new compression stations for the proposed Ruby Project, while no new compression would be necessary for the Bradwood Landing Project.

After PG&E pulled out as a project sponsor, James Yardley, chairman of El Paso's Pipeline Group, told industry analysts that his firm has "not yet committed to go forward with Ruby." Yardley further indicated that El Paso would only move ahead with the Ruby, "if we see a return on the project" (Energy Daily, 2008). Although El Paso completed an open season in April 2008, Bruce Connelly, vice president of investor and media relations, indicated the company would be going back to committed and potential shippers with new cost estimates (Inside FERC, 2008c).

Bronco

The Bronco Pipeline Project is being proposed by Spectra. While Spectra has not identified a specific route for the pipeline, it would extend almost 700 miles from Opal, Wyoming to Malin, Oregon. The purpose of the Bronco Pipeline Project would be to transport Rocky Mountain gas to the Pacific Northwest and California markets. The pipeline would have a capacity of about 1 Bcfd. In January 2008, Spectra initiated an open season to gauge market interest. The scope and timing of the project would depend on the results of the open season (Natural Gas Intelligence, 2008b). Spectra indicated that it may go forward with its project even if LNG import terminals are eventually authorized and built in Oregon, because the Bronco pipeline would offer customers in the growing markets of northern Nevada and northern California competitive choices of domestically produced gas versus imported LNG (Natural Gas Intelligence, 2007). While the BLM indicated that a Right-of-Way Grant application was submitted for the Bronco pipeline to cross federal lands, at this time Spectra has not yet requested that the FERC begin the initiation of the Pre-filing environmental review process for its project.

The Bronco Pipeline Project would have no clear environmental advantages over the Bradwood Landing Project. The Bronco pipeline would be almost 700 miles long, while the Bradwood Landing sendout pipeline would be about 36 miles long. Spectra has not yet announced the results of its open season for the Bronco Pipeline Project, which ended in February 2008. A Spectra representative indicated that the project "may not work out as we originally saw it." Other industry analysts speculate that the Bronco project may be canceled because of competition from the Ruby Project and Williams' Sunstone Project, which would serve the same purpose and need (Inside FERC, 2008a).

Sunstone and Blue Bridge Projects

In January 2008, Williams, in partnership with TransCanada, sent out a letter to prospective customers to determine interest in expanding its existing Williams Northwest pipeline system between Wyoming and Oregon (Williams, 2008). The potential expansion would consist of a new pipeline, to be known as the Sunstone Project, designed to transport about 1.2 Bcfd of natural gas. The Sunstone Project would consist of a new 618-mile-long, 42-inch-diameter pipeline parallel to the existing Williams Northwest mainline from Opal, Wyoming to an interconnection with the GTN system near Stanfield, Oregon. The purpose of the Sunstone Project would be to transport natural gas produced in the Rocky

Mountain region and the WCSB to markets in the Pacific Northwest, northern Nevada, and northern California (Natural Gas Intelligence, 2008e).

In March 2008, Williams and PSE announced their joint plans to develop the so-called Blue Bridge Project. This would consist up to about 170 miles of 30- and 36-inch-diameter pipeline extending from the terminus of the Sunstone Project at Williams Northwest's existing interconnection with GTN at Stanfield, Oregon to Seattle, Washington. The Blue Bridge Project would also require the addition of compression at Williams Northwest's existing Plymouth, Washougal, and Chehalis compressor stations in Washington. The Blue Bridge Project would make available up to 500,000 decatherms per day (Dthd) of natural gas from Rocky Mountain and WCSB producers (Steis, 2008). PSE, an LDC serving customers in western Washington, indicated it would be the anchor shipper on the pipeline, and may become an equity investor in the project.

We consider the Sunstone and Blue Bridge projects to be in the speculation stage. Williams and its partners are still weighting customer interest in these projects. The open season for the Blue Bridge Project is expected to continue through May 2008. Williams and its partners have not yet come to the FERC to discuss their plans, or seek the initiation of the FERC Pre-filing environmental review process for either the Sunstone or Blue Bridge projects.

Conclusions about Newly Proposed Pipelines as System Alternatives

We do not yet have detailed data about the potential environmental impacts of the proposed Palomar, Ruby, Bronco, or Sunstone/Blue Bridge pipeline projects. Palomar and Ruby are being reviewed by the FERC under our Pre-filing process. Palomar filed its initial draft environmental Resource Report 1 (Project Description) on September 28, 2007, but indicated it would not be providing the remainder of its first drafts of environmental resource reports until May 2008, or later. Ruby filed its initial draft environmental Resource Report 1 on April 1, 2008. In the case of the Bronco and Sunstone/Blue Bridge projects, no proposals have been made before the FERC yet, and we consider these projects to be speculative in nature at this time.

As indicated in table 3.1.2-1, all of these pipelines would be substantially longer than the sendout pipeline proposed by NorthernStar. The Palomar pipeline would be about 215 miles long, the Ruby pipeline would be about 655 miles long, the Sunstone pipeline would be about 618 miles long, and the Blue Bridge pipeline would be about 170 miles long. It stands to reason that a longer pipeline may have more environmental impacts. As of the date of the writing of this EIS, we have no detailed information about the kind of resources that may be affected by construction of the Palomar, Ruby, Bronco, or Sunstone/Blue Bridge pipelines, including their potential effects on waterbodies, wetlands, soils, vegetation, wildlife, and cultural resources. Therefore, these proposed pipelines would not be environmentally preferable system alternatives to the Bradwood Landing Project.

TABLE 3.1.2-1				
Comparison of Proposed Project to Pipeline Projects as System Alternatives				
Pipeline/Project	Gas Source	Target Market	Estimated Completion Date	Impacted Mileage
Bradwood Landing	LNG	Primarily OR & WA	2011	36.3
Ruby	U.S. Rockies	Primarily CA & NV	2011	655
Bronco	U.S. Rockies	CA, NV and OR	2012	700
Sunstone/Blue Bridge	U.S. Rockies	WA, OR, NV and CA	2011	618/170
Palomar	Canada & U.S. Rockies	Portland Area	2012	215

It is questionable if either the Ruby or Bronco projects could meet the objectives of the proposed Bradwood Landing Project. The main purpose of the Ruby and Bronco pipelines is to transport Rocky Mountain gas to markets in northern Nevada and northern California, through interconnections with the existing PG&E and Tuscarora systems at the Oregon/California border. It is possible that gas could be backhauled through the existing GTN system at its interconnection with either the Ruby or Bronco pipeline near Malin, Oregon to serve markets in the Pacific Northwest. However, that would be against the current flow of gas in the GTN system, and it would be a longer distance to transport the gas to southern Washington than the sendout pipeline proposed by NorthernStar that would interconnect with the existing Williams Northwest system near Kelso, Washington. The main objective of the Bradwood Landing Project is to import LNG as a new source of natural gas for the Pacific Northwest.

Like the Ruby and Bronco pipelines, the Sunstone Project would bring additional volumes of Rocky Mountain gas to Oregon. The target markets for the Sunstone Project include the Pacific Northwest, northern Nevada, and northern California. Williams indicated that this project is intended to provide an option to utilize currently unsubscribed capacity on GTN's existing mainline between Stanfield and Malin, Oregon. The Sunstone Project was pitched by Williams to prospective customers as an alternative to compete with the proposed Ruby pipeline (Williams, 2008).

Both the Palomar Project and NorthernStar proposal could serve similar markets, but with different sources of natural gas. Palomar would transport most of its gas from Canada; obtained from GTN. A number of studies have predicted that Canadian exports into the western United States are not likely to increase in the future, and may even decline as production in the WCSB levels off over time and additional customers in Canada are served. Palomar could supplement its supplies using Rocky Mountain gas obtained through its interconnections with Williams Northwest. Whereas, the LNG to be imported by NorthernStar would probably come from places outside of North America (mainly the Pacific Basin, but Alaska is another possible source). Therefore, these projects may not be mutually exclusive, as they would diversify the supply of natural gas from different sources to the Pacific Northwest.

There would also be environmental challenges associated with the Palomar pipeline. The proposed route of the Palomar pipeline would go over the Coast and Cascade mountain ranges and through old growth forest habitat for federally listed threatened and endangered species, including the marbled murrelet and the northern spotted owl. In addition, it would cross agricultural land and vineyards in the Willamette Valley. The proposed route for the Bradwood Landing sendout pipeline would be shorter, follow an existing right-of-way for a greater percent, traverse less steep terrain, clear less forest, impact less agricultural land, and cross fewer waterbodies and wetlands than the proposed Palomar pipeline.

All of these other proposed pipeline projects may be on different time frames for beginning service than the Bradwood Landing Project. None have filed applications with the FERC yet, and it is unclear if they could be reviewed, approved, and constructed on a schedule similar to the Bradwood Landing Project. The FERC initiated the Pre-filing review of the Palomar Project at the end of August 2007, and started the Pre-filing review of the Ruby Project at the end of January 2008. The Bronco and Sunstone/Blue Bridge projects have not yet come to the FERC seeking the initiation of Pre-filing environmental reviews. NorthernStar, on the other hand, filed its applications for the Bradwood Landing Project in September 2006, and the FERC issued a draft EIS in August 2007. If the Commission authorizes the Bradwood Landing Project by the end of 2008, the LNG import terminal could be in operation by the end of 2011.

It is possible that market conditions could make some of the currently planned new pipelines from the Rockies to Oregon not viable. Spectra indicated that it is reconsidering whether it can go forward with the Bronco pipeline, based on the results of its open season. El Paso lost PG&E as a partner

due to the high price of steel pipe, is revisiting the costs of the Ruby pipeline with committed and prospective shippers, and would further develop the project only if it makes sense from an economic standpoint. Williams has not yet concluded open seasons for its proposed Sunstone and Blue Bridge projects.

3.1.2.3 Existing LNG Facilities

Existing LNG Import Terminals in the United States

There are four existing onshore LNG import terminals in operation in the United States (in Massachusetts, Maryland, Georgia, and Louisiana) and one offshore facility (in the Gulf of Mexico). In addition, there are three newly authorized onshore LNG import terminals currently under construction along the Gulf Coast (in Louisiana and Texas). None of the existing or under-construction LNG import terminals would be a reasonable or feasible system alternative to the proposed project because of their distance from the proposed market area.

Numerous new LNG import terminals are proposed throughout the United States. The FERC has recently authorized eight onshore LNG import facilities along the Gulf Coast (three projects in Corpus Christi, Texas; one in Port Arthur, Texas; one in Sabine Pass, Texas; one in Cameron, Louisiana; and two in Pascagoula, Mississippi), and two in the Northeast (Massachusetts and New Jersey); although final design construction has not yet begun at any of these approved facilities. We did not study any of the authorized but not yet built LNG import terminals located along the East or Gulf Coasts as potential system alternatives to the Bradwood Landing Project, since we do not consider them to be reasonable or feasible alternatives because of their distance from the proposed market area.

Existing LNG Storage Facilities in the Pacific Northwest

Five LNG storage facilities currently exist in the Pacific Northwest (see figure 3.1.2-2). These are peak shaving plants that liquefy natural gas, store it as LNG, and then vaporize the LNG back into natural gas for use during periods of peak demand. These facilities do not add new supplies of natural gas to the region, but rather act as storage facilities, using existing supplies, to even out the discrepancies created by varying seasonal demands.

In Oregon, Northwest Natural owns and operates two peak shaving LNG storage plants. One is located in Portland, and has a 28,000 m³ tank with a storage capacity of 600 million standard cubic feet (MMscf). The other is located in Newport and has a 48,000 m³ tank and a storage capacity of 1.0 billion standard cubic feet. In Washington, Williams Northwest owns and operates a peak shaving LNG storage plant in Plymouth with a liquefaction capacity of 19.7 Mscf, a storage capacity of 60,000 m³, and a vaporization capacity of 300 Mscf. In Gig Harbor, Washington, PSE operates a small LNG peak shaving plant with a capacity of 31 thousand decatherms (MDth), and a maximum withdrawal rate of 3 MDthd. In Nampa, Idaho, Intermountain Gas operates an LNG peak shaving plant with a capacity of 588 MDth and a maximum withdrawal of 60 MDthd (NWGA, 2007).

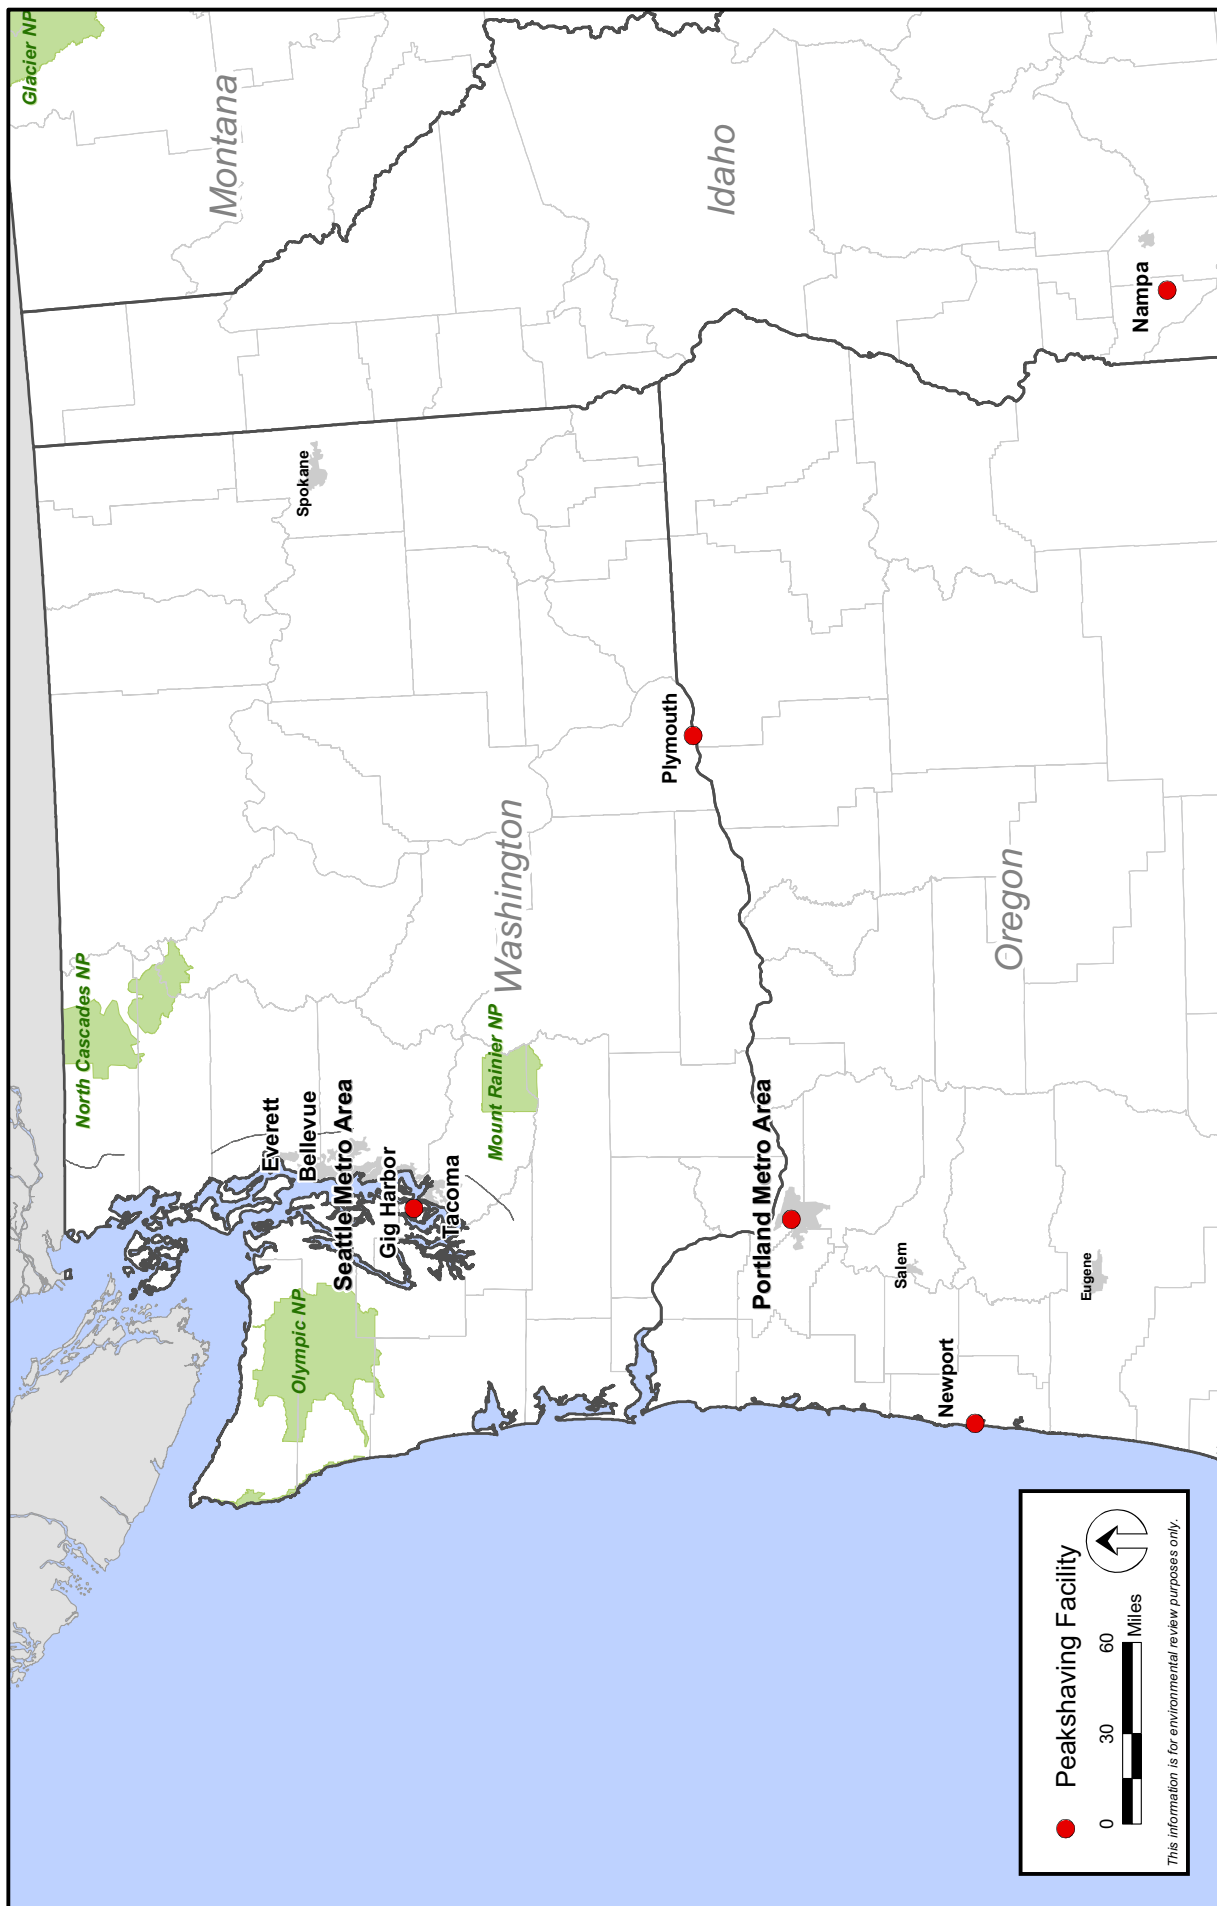

Figure 3.1.2-2
Bradwood Landing Project
 Existing Peakshaving Facility Locations

We considered the possibility of converting one of the existing peakshaving LNG storage plants into an LNG import terminal as a system alternative to the proposed project. However, such an alternative would likely not be economically viable due to the small size and limited capacity of the existing storage facilities. At these locations there is not enough additional vacant land around the existing facilities to allow them to be expanded and converted into import terminals. Only the two LNG storage facilities in Oregon are located on a waterway that would be potentially reachable by an LNG carrier. While Plymouth is located on the Columbia River, it is upriver of several dams, and so it would not be accessible to LNG carriers. Although Gig Harbor is located on Puget Sound, the PSE peakshaving facility is located about 1 mile from the harbor and would not be accessible to LNG carriers. While it may be feasible to construct a pipeline to transmit LNG from the harbor to the PSE peakshaving facility, such a pipeline would have additional associated environmental impacts. The Portland facility is located on the Willamette River and would potentially be accessible to LNG carriers. However, the waterway for LNG marine transit would be over 100 miles long and the navigation channel is obstructed by a bridge at Ross Island that only has clearances of 120 feet high and 100 feet wide. Newport is on the Oregon coast; however, the port of Newport is relatively small, with channel depths ranging from 20 to 30 feet. The port at Newport could not accommodate LNG carriers without extensive dredging. We estimate at least 16 million cubic yards of material would need to be dredged to accommodate LNG carriers at this location. Therefore, we conclude that converting existing peakshaving LNG storage plants in the region into LNG import terminals is not a reasonable or feasible system alternative to the proposed project.

3.1.3 Proposed West Coast Alternative LNG Import Terminals

We assessed proposals for offshore and onshore LNG import terminals to be located on the Pacific Coast of North America, including facilities proposed on the West Coast of Mexico, Canada, and the United States (see figure 3.1.3-1).

3.1.3.1 Proposed LNG Import Terminals on the West Coast of Mexico

The proposed LNG import terminals on the West Coast of Mexico include two offshore facilities (Terminal GNL Mar Adentro de Baja California and Moss-Maritime LNG Project) and two onshore facilities (Terminal GNL de Sonora and Energia Costa Azul LNG terminal). The Terminal GNL Mar Adentro de Baja California, proposed by Chevron Corporation (Chevron), would have been a gravity-based structure (GBS) (see section 3.1.4.1) located near the Coronado Islands off the coast of Tijuana with a projected average sendout capacity of 700 MMcfd. In March 2007, Chevron announced it was dropping its plans to develop its proposed Baja, Mexico LNG import terminal (East Bay Business Times, 2007). The Moss-Maritime LNG Project, proposed by a partnership between Moss-Maritime and Terminales y Almacenes Maritimos de Mexico, would be a floating storage and regasification unit (FSRU) (see section 3.1.4.1). The terminal would be located about 5 miles from Rosarito Beach off the coast of Baja, Mexico and have an average sendout capacity of 297 MMcfd. This facility was granted a permit from the Mexican government, but its current status is unknown (Lindquist, 2007).

The Terminal GNL de Sonora would be an LNG import terminal located near Puerto Libertad, Sonora, on the eastern shore of the Gulf of California (Sea of Cortez), with a sendout capacity of 1.3 Bcfd, proposed by El Paso Corporation (El Paso) and DKRW Energy LLC. The partners have received three environmental permits from the Mexican Federal Ministry of the Environment and Natural Resources. Gas supply for this facility still needs to be secured, and in May 2006 El Paso announced it was halting plans for a 59-mile-long sendout pipeline that would link the proposed terminal to markets in Tucson (CEC, 2007b).

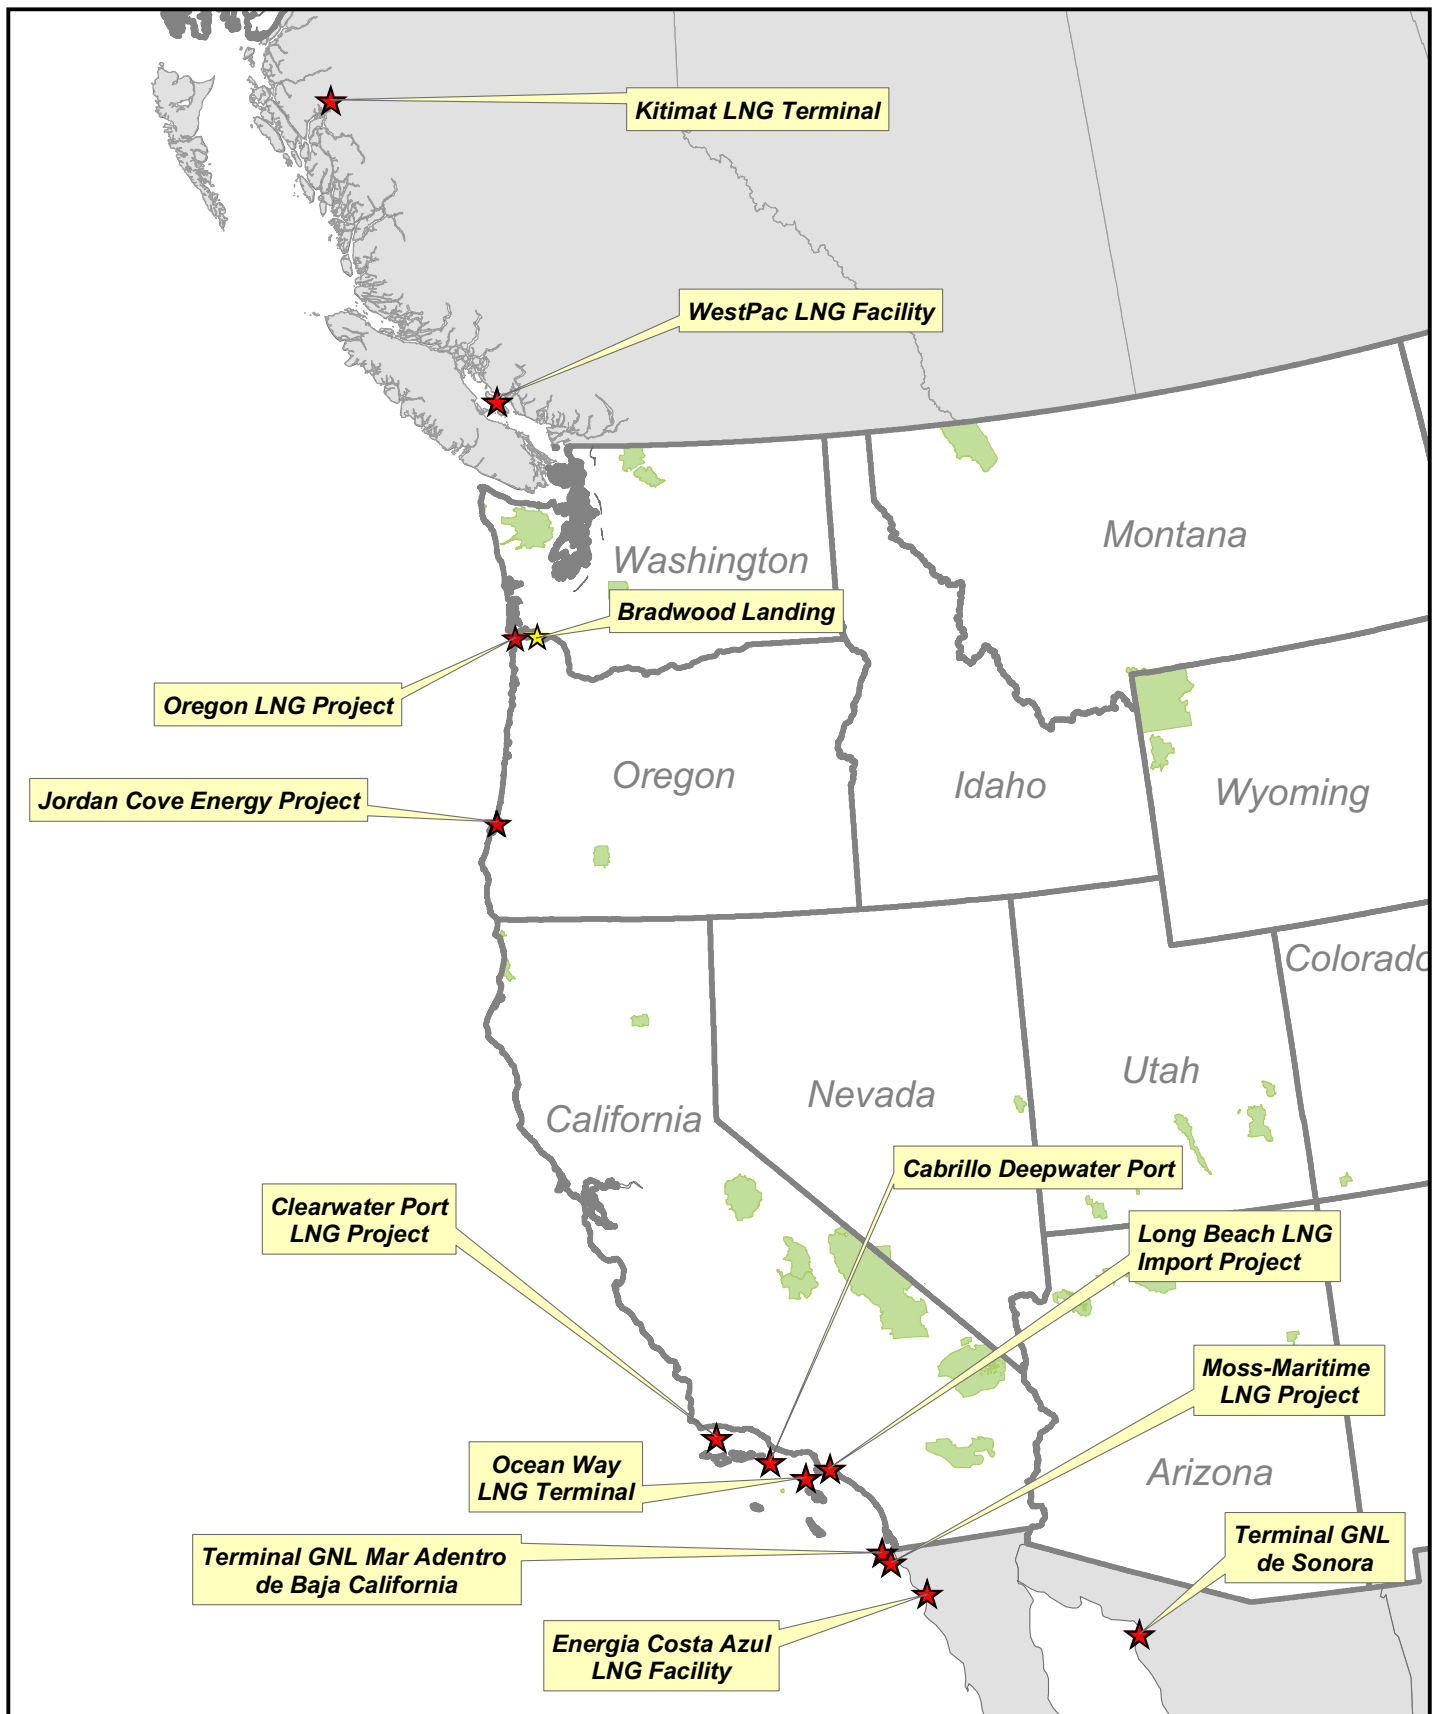

Figure 3.1.3-1
Bradwood Landing Project
 Proposed LNG Terminals on West Coast

The Energia Costa Azul LNG terminal (Costa Azul), proposed by Semptra Energy LNG Corporation, is located near Ensenada, on the Pacific Coast of Baja, Mexico. The terminal is sited within a 400-acre parcel, with two full containment LNG storage tanks with a total capacity of 320,000 m³, open rack vaporizers (ORV), and a 42-mile-long, 36-inch-diameter pipeline with an average sendout capacity of 1.0 Bcfd. All permits have been secured for this facility and it is currently under construction. It is expected to be in operation late in the second quarter of 2008. In March 2008, Costa Azul awarded a \$100 million contract to Fluor Corporation to build a nitrogen injection system and power generation facilities within its LNG terminal tract (CEC, 2008b).

The target markets for the LNG import terminals on the West Coast of Mexico would be northern Mexico, southern California, and other states in the southwestern United States (Arizona and Texas). The CEC (2007c) estimated that up to 50 percent of the capacity of the Costa Azul LNG terminal would be contracted for use in Mexico, with the remainder available for southern California markets. Natural gas from Costa Azul would be conveyed into southern California via the existing intrastate pipeline systems of Southern California Gas (SoCal) and San Diego Gas and Electric Companies, both subsidiaries of Semptra, the owner of Costa Azul. The proposed LNG import terminals in northern Mexico would be far from the market area proposed for the Bradwood Landing Project and could not meet the objective of providing natural gas to the Pacific Northwest without substantially increasing the capacity of the terminals and constructing over 1,000 miles of new pipeline with compressor stations. Therefore, we do not consider the Mexican LNG terminals to be reasonable or feasible alternatives to the proposed project and did not evaluate them further.

3.1.3.2 Proposed LNG Import Terminals on the West Coast of Canada

One proposed onshore LNG import facility (WestPac) in British Columbia, Canada, has not yet begun the environmental review process for its revised project, while another LNG import terminal (Kitimat) has received regulatory approval and is planning to begin construction in the near future.

WestPac LNG Terminal, British Columbia

WestPac LNG Corporation proposes to construct and operate an LNG import terminal near Kiddie Point on Texada Island, about 75 miles northwest of Vancouver in Georgia Strait, British Columbia, Canada. Originally, WestPac started the environmental review process with the Prince Rupert Port Authority in 2006 for an LNG terminal site on Ridley Island (CEC, 2008a). The proposed location of the LNG terminal was moved to Texada Island in July 2007. The terminal would include a marine wharf capable of handling up to about 36 LNG carriers per year, with capacities up to 165,000 m³. Onshore there would be two full-containment LNG storage tanks, re-gasification facilities, and an electric generation plant. While WestPac indicated it would have access to the Vancouver Island gas pipeline, it did not reveal any details about its sendout pipeline. Instead, WestPac indicated that it would provide a detailed project description with the application it intends to file with the British Columbia and Canadian Environmental Assessment Offices early in 2009 (WestPac LNG, 2008). In January 2008, the sponsors put the project on hold pending review of initiatives that may be taken by the provincial government of British Columbia related to emission or climate change regulations (Gas Daily, 2008).

The WestPac LNG facility may be considered as a potential alternative to the proposed Bradwood Landing Project, if the project were to include pipeline connections to the existing grid, enabling the transportation of natural gas to markets in the western United States. However, at the present time it is unclear what the target markets may be for this project, and how gas would be transported from the LNG terminal to end users. In addition, environmental review of the proposal would not resume until 2009, and there is uncertainty over whether or not the appropriate Canadian government authorities would

approve the project. Therefore, we do not consider the WestPac LNG terminal to be a feasible alternative to replace the Bradwood Landing Project.

Kitimat LNG Terminal, British Columbia

The Kitimat LNG terminal, proposed by a subsidiary of Galveston LNG, Inc. would be located at Bish Cove, about 8 miles south-southwest of the Port of Kitimat, British Columbia. The facility would receive four or five LNG shipments per month. The LNG terminal design includes marine offloading, two 160,000 m³ LNG storage tanks, natural gas liquids recovery, and regasification facilities, with a nominal sendout capacity of 1 Bcfd of natural gas. The terminal would deliver gas via a 9-mile-long pipeline into the Pacific Trails Pipeline, to be operated by a partnership between Galveston LNG, Inc. and Pacific Northern Gas Ltd. This would be a new 292-mile-long pipeline extending from Kitimat to Summit Lake, British Columbia, where it would interconnect with the existing Spectra Energy Transmission (Spectra) (formerly Duke Energy) pipeline system (Kitimat LNG, 2008). An environmental assessment was completed for the Kitimat LNG terminal, and the project was approved by the Canadian Environmental Ministry in August 2006. Pacific Trails Pipeline filed a formal environmental application with the British Columbia Environmental Assessment Office in August 2007 (CEC, 2008a). The Kitimat developers expect to have their LNG terminal in operation by the end of 2010.

The Kitimat LNG terminal appears to be a potential alternative for providing the Pacific Northwest with additional volumes of natural gas through new sources of imported LNG. However, one of the main goals of the Kitimat LNG Project is to provide natural gas to the tar sands oil production area of Alberta, Canada; one of the fastest growing natural gas markets in North America. Further, interconnections from the Spectra and TransCanada pipeline systems would allow natural gas from Kitimat to be transported to Midwest and eastern United States markets through the existing Northern Border, Alliance, and Iroquois pipeline systems. Thus, only a portion of the natural gas from Kitimat would probably be available for delivery to markets along the West Coast of the United States. The volume of gas from Kitimat would be smaller and would need to be transported a longer distance to reach the market center of Portland, Oregon, than gas from Bradwood Landing. Therefore, the Kitimat LNG terminal could not satisfy all of the objectives of the Bradwood Landing Project.

3.1.3.3 Proposed LNG Import Terminals on the California Coast

There are five offshore (Cabrillo, Clearwater, Ocean Way, Pacific Gateway, and Esperanza) and one onshore (Long Beach) LNG import terminals proposed for the Pacific Coast in California.

Long Beach LNG Import Terminal Project

The Long Beach LNG Import Terminal Project was proposed by Sound Energy Solutions (SES), a joint venture between Mitsubishi Corporation and ConocoPhillips, in FERC Docket Nos. CP04-58-000 et al., to be located within the Port of Long Beach, California. Features of the terminal include a berth capable of handling an LNG carrier up to about 200,000 m³ capacity in size, two LNG storage tanks with a combined capacity of 320,000 m³, four shell and tube vaporizers (STV), and a typical sendout capacity of 700 MMcfd of natural gas. A 2.3-mile-long 36-inch-diameter pipeline would be constructed to transport natural gas from the LNG terminal to existing SoCal facilities. In addition, a 4.6-mile-long 10-inch-diameter pipeline would be constructed to transport vaporized ethane from the LNG terminal to an existing ConocoPhillips plant. In October 2005, the FERC and Port of Long Beach produced a joint draft EIS for this project.

In January 2007, the Long Beach Board of Harbor Commissioners, who would be responsible for leasing the property for the LNG terminal, decided to end its environmental review (Polakovic, 2007). In

March 2008, the FERC issued a letter to SES stating that staff would no longer work on its application for an LNG import terminal at Long Beach, because the company could not document that it had access to or control over its proposed terminal site. SES appealed the City of Long Beach's decision through the local judicial system. However, in March 2008 a Superior Court judge ruled against SES, finding that Long Beach had acted in an appropriate manner in halting its environment review process (CEC, 2008b).

California Offshore LNG Import Terminal Proposals

All of the proposed LNG terminals off the California shore would be reviewed by the Coast Guard and U.S. Department of Transportation, Maritime Administration (MARAD) under the authority of the Deepwater Port Act.

Cabrillo Deepwater Port LNG Facility

The Cabrillo Deepwater Port LNG Facility, proposed by BHP Billiton, would be located in the Santa Barbara Channel about 14 miles from Point Mugu. The import facility would consist of an FSRU permanently moored to the ocean floor, with three independent Moss spherical storage tanks mounted within the hull together with eight vaporizers. An underwater 30-inch-diameter pipeline would extend about 21 miles, coming ashore in the vicinity of Ormond Beach in Ventura County, California, and interconnecting with the existing SoCal system. The facility would have the ability to send out an average of about 800 MMcfd of natural gas.

The Coast Guard and California State Lands Commission (CLC) issued a final EIS for this project in March 2007. In April 2007, the CLC and the California Coastal Commission voted against authorizing the Cabrillo Deepwater Port LNG import facility. California Governor Arnold Schwarzenegger rejected BHP Billiton's proposal in May 2007. According to the DOT Docket Management System, on June 5, 2007, the MARAD issued a Record of Decision denying the application for the Cabrillo Deepwater Port.

Clearwater Port LNG Project

The Clearwater Port LNG Project was proposed by NorthernStar Natural Gas, Inc., the same developers promoting the Bradwood Landing Project. The Clearwater Port project would use existing offshore Platform Grace, located in the Santa Barbara Channel about 13 miles from Oxnard. A new floating dock would need to be installed adjacent to the existing platform to moor LNG carriers during transfer. No storage facilities are proposed. The platform would be reconfigured to accommodate vaporizers. The natural gas would be delivered from the platform to the shore via a new 32-inch-diameter, 13-mile-long subsea pipeline. An additional 12-mile-long underground pipeline would convey the gas onshore from Oxnard to an interconnection with the existing SoCal system near Camarillo. The average sendout capacity of the facility would be about 1.2 Bcfd.

NorthernStar filed its application for the proposed Clearwater Port with the MARAD on January 28, 2004. On August 23, 2007, the application was deemed complete, and on September 18, 2007 the MARAD issued a notice of intent to produce a draft EIS for the project. On October 23, 2007, the Coast Guard issued a "stop the clock" letter to the applicant with a list of 396 questions (DOT, 2007; CEC, 2008a). This project would need the approval of the Governor of California before it could go forward.

Ocean Way LNG Terminal

The Ocean Way LNG Terminal, to be located in the Pacific Ocean about 22 miles south of Los Angeles, California, is proposed by Woodside Energy, Inc. (Woodside). The project would include a

mooring facility and an underwater pipeline that would come onshore near Los Angeles International Airport and interconnect with the existing SoCal intrastate local distribution system. The LNG would be regasified while still on board the ship, and the facility would have a first phase nominal sendout capacity of about 400 MMcfd.

Woodside filed its application with the MARAD on August 18, 2006. In September 2007 the application was deemed complete, and a notice of intent was issued indicating that a draft EIS would be prepared by the appropriate federal agencies and the City of Los Angeles. The clock was stopped on this project on November 23, 2007, when the Coast Guard issued a letter to Woodside with a list of 61 questions (CEC, 2008a). The Coast Guard suspended its environmental review of Woodside's proposal pending the completion of a global lifecycle assessment of GHG impacts of the proposed ship-to-ship transfer and regasification processes (Natural Gas Intelligence, 2008f).

Pacific Gateway LNG Facility

The Pacific Gateway LNG Facility is proposed by Excelerate Energy LLC (Excelerate) to be located off the shore of northern California. Excelerate, which currently operates an offshore LNG import terminal in the Gulf of Mexico, would use specially designed LNG tankers for the transportation of LNG and vaporization into natural gas. The northern California proposal would deliver up to 1.0 Bcfd of natural gas. This project is currently in the conceptual design phase, with Excelerate conducting "fatal flaw" analyses of offshore terminal locations and pipeline routes (Excelerate, 2007). An application under the Deepwater Port Act has not yet been submitted for this project.

Esperanza LNG Terminal

In March 2007, Esperanza Energy LLC (Esperanza), a subsidiary of Tidelands Oil and Gas Corporation, announced plans for an offshore LNG import terminal to be located in the Pacific Ocean about 15 miles from Long Beach, California. This facility would use the proprietary HiLoad system developed by TORP Technology to vaporize LNG as it is offloaded from ships. The natural gas would be transported to shore by an undersea pipeline, with a sendout capacity of about 1.2 Bcfd. The project is intended to serve existing onshore gas-fired electric generation plants in the Long Beach-Huntington Beach area. One unique feature of this proposal would be the use of warm water discharged from an onshore host to regasify the LNG. Esperanza is considering the construction of a directionally drilled tunnel, 100 feet underground, that could provide a conduit for water, communication, and electric lines, together with its sendout pipeline linking its offshore import terminal with SoCal's existing local distribution system. Esperanza has not yet filed its application under the Deepwater Port Act. Apparently, Esperanza also has to address the issue of GHG emissions, and has not yet lined up financing for the project (Esperanza, 2007; Natural Gas Intelligence, 2007, 2008f).

California LNG Import Terminal Conclusions

None of the proposed LNG import terminals in California are viewed as reasonable or feasible alternatives to the Bradwood Landing Project because the target markets for these projects are in southern California. None of these proposals have been authorized at this time. In fact, some (Pacific Gateway and Esperanza) are in the speculation stage, with no applications yet submitted. In addition, the target markets for these projects are in southern California. The California LNG import terminal proposals, therefore, could not meet the objectives of the Bradwood Landing Project to supply the States of Oregon and Washington with new sources of natural gas.

3.1.3.4 Proposed LNG Import Terminals in Oregon

There are three other potential LNG import terminal alternative locations along the Columbia River, in addition to the Bradwood Landing Project, and one in Coos Bay. These are compared in table 3.1.3-1 and described below.

TABLE 3.1.3-1					
Comparison of Proposed LNG Import Terminals in Oregon					
Variable	Jordan Cove Energy LNG	Oregon LNG	Tansy Point	Port Westward	Bradwood Landing
Acreage affected by construction at LNG terminal	159	208	50	Not Available	148
Dredging required for turning basin or berth	5.6 million cubic yards	1.3 million cubic yards	minimal	Est. 0.6 million cubic yards	0.7 million cubic yards
Residential structures within 0.5 mile of terminal	0	0	> 85	0	0
Annual roundtrip LNG carrier traffic	80 carriers	100 carriers	Not Available	Not Available	125 carriers
Acres of wetland affected by terminal	11.3	21	9	2.6	14.8
Sendout pipeline length	230 miles	130 miles	58 miles	33 miles ^a	36 miles
Residences within 50 feet of pipeline construction right-of-way	15	At least 14	Not Available	Not Available	3
Compressor Stations	1	1	1	0	0
Acreage affected by construction along pipeline	4,920	1,461	793	430	553
Miles of public lands crossed	80	9	5	0.2	3
Number of federally listed threatened and endangered species affected by project	11	34	Not Available	Not Available	37
Number of waterbodies crossed by pipeline	379	192	90	55	94
Acres of wetland affected by pipeline construction	406	126	139	51	97.9
Acres of forest crossed by pipeline	1,906	57	Not Available	Not Available	179.7
Acres of agricultural land crossed by pipeline	587.3	45	Not Available	Not Available	98.6
Number of identified archeological sites along pipeline route ^b	88	9	Not Available	Not Available	4
^a Includes lateral to Wauna Mill and Northwest Natural interconnects.					
^b All affected parcels have not yet been surveyed.					

Jordan Cove Energy LNG Project

On September 4, 2007, Jordan Cove Energy Project, L.P. (Jordan Cove) filed an application with the FERC in Docket No. CP07-444-000 for a proposed LNG import terminal in Coos Bay, Oregon. At the same time, Pacific Connector Gas Pipeline, L.P. (PCGP) filed its application, in Docket No. CP07-441-000 for a sendout pipeline associated with the LNG import terminal. The FERC intends to produce an EIS for the Jordan Cove LNG terminal and PCGP sendout pipeline combined. The COE, Coast Guard, EPA, BLM, USFS, and Douglas County are cooperating agencies in the production of the EIS.

The Jordan Cove LNG import terminal would be located at about Mile 7.5 along the Coos Bay navigation channel, on the eastern shore of the North Spit in Coos County, Oregon. Proposed facilities would include a single berth capable of handling about 80 LNG carriers per year, 2 full containment LNG storage tanks, each with a net volume of 160,000 m³, and 6 SCVs with a sendout capacity of 1 Bcfd. The terminal would also include a natural gas liquids extraction facility and a 37 MW natural gas fired power plant.

PCGP's sendout pipeline would consist of a 230-mile-long 36-inch-diameter pipeline, extending from the Jordan Cove LNG import terminal across Coos, Douglas, Jackson, and Klamath Counties, terminating at interconnections with PG&E and Tuscarora near Malin, Oregon. Aboveground facilities associated with the pipeline include a 20,620 hp compressor station near Butte Falls and four meter stations (see figure 3.1.3-2).

The PCGP sendout pipeline would be more than six times longer than NorthernStar's pipeline. PCGP's pipeline route would have to go over difficult terrain of the Coastal Range and the Cascade Range, and cross lands administered by four BLM districts (Coos Bay, Roseburg, Medford, and Lakeview) and portions of the Fremont-Winema, Rogue River-Siskiyou, and Umpqua National Forests administered by the FS. On federal lands, the pipeline would cross about 25 miles of habitat categorized as Late Successional Reserves, 45 miles of Matrix, and almost 2 miles of Riparian Reserves. The route would go through old growth forest habitat occupied by federally listed threatened and endangered species. Biological surveys in 2007 resulted in 114 detections at 14 activity centers for northern spotted owls, 4 stands found to be occupied by nesting marbled murrelets, and 23 confirmed active nests for the red tree vole. In addition, one site of large-flowered wooley meadowform, and three sites of Kincaid's lupine were identified (Siskiyou BioSurvey, 2007). The proposed pipeline would also cross 379 waterbodies and potentially impact about 406 acres total of wetlands. Preliminary cultural resources surveys identified 88 archaeological sites along segments of the pipeline route (HRA, 2007).

Jordan Cove and PCGP indicate that their project would supply natural gas to the Pacific Northwest, northern Nevada, and northern California. In some respects, that is similar to the objectives of NorthernStar's project. There are no clear environmental advantages of the Jordan Cove LNG Project over the Bradwood Landing Project; therefore, it is not a preferable alternative.

Oregon LNG Project

On June 10, 2007, the FERC agreed to the request from LNG Development Company LLC and the Oregon Pipeline Company (hereafter referred to together as Oregon LNG) to initiate the Pre-filing environmental review of their proposed Oregon LNG Project, in Docket No. PF07-10-000. This project would consist of an LNG import terminal in Warrenton, Clatsop County, Oregon, and an associated 121-mile-long sendout pipeline crossing Clatsop, Tillamook, Washington, Yamhill, Marion, and Clackamas Counties, Oregon. The development of an LNG import terminal at Warrenton was originally proposed by Calpine Corporation (Calpine). However, after Calpine declared bankruptcy, rights to the project were transferred to Oregon LNG, a subsidiary of the Leucadia National Corporation. The FERC intends to produce a separate, stand alone, independent EIS for the Oregon LNG Project.

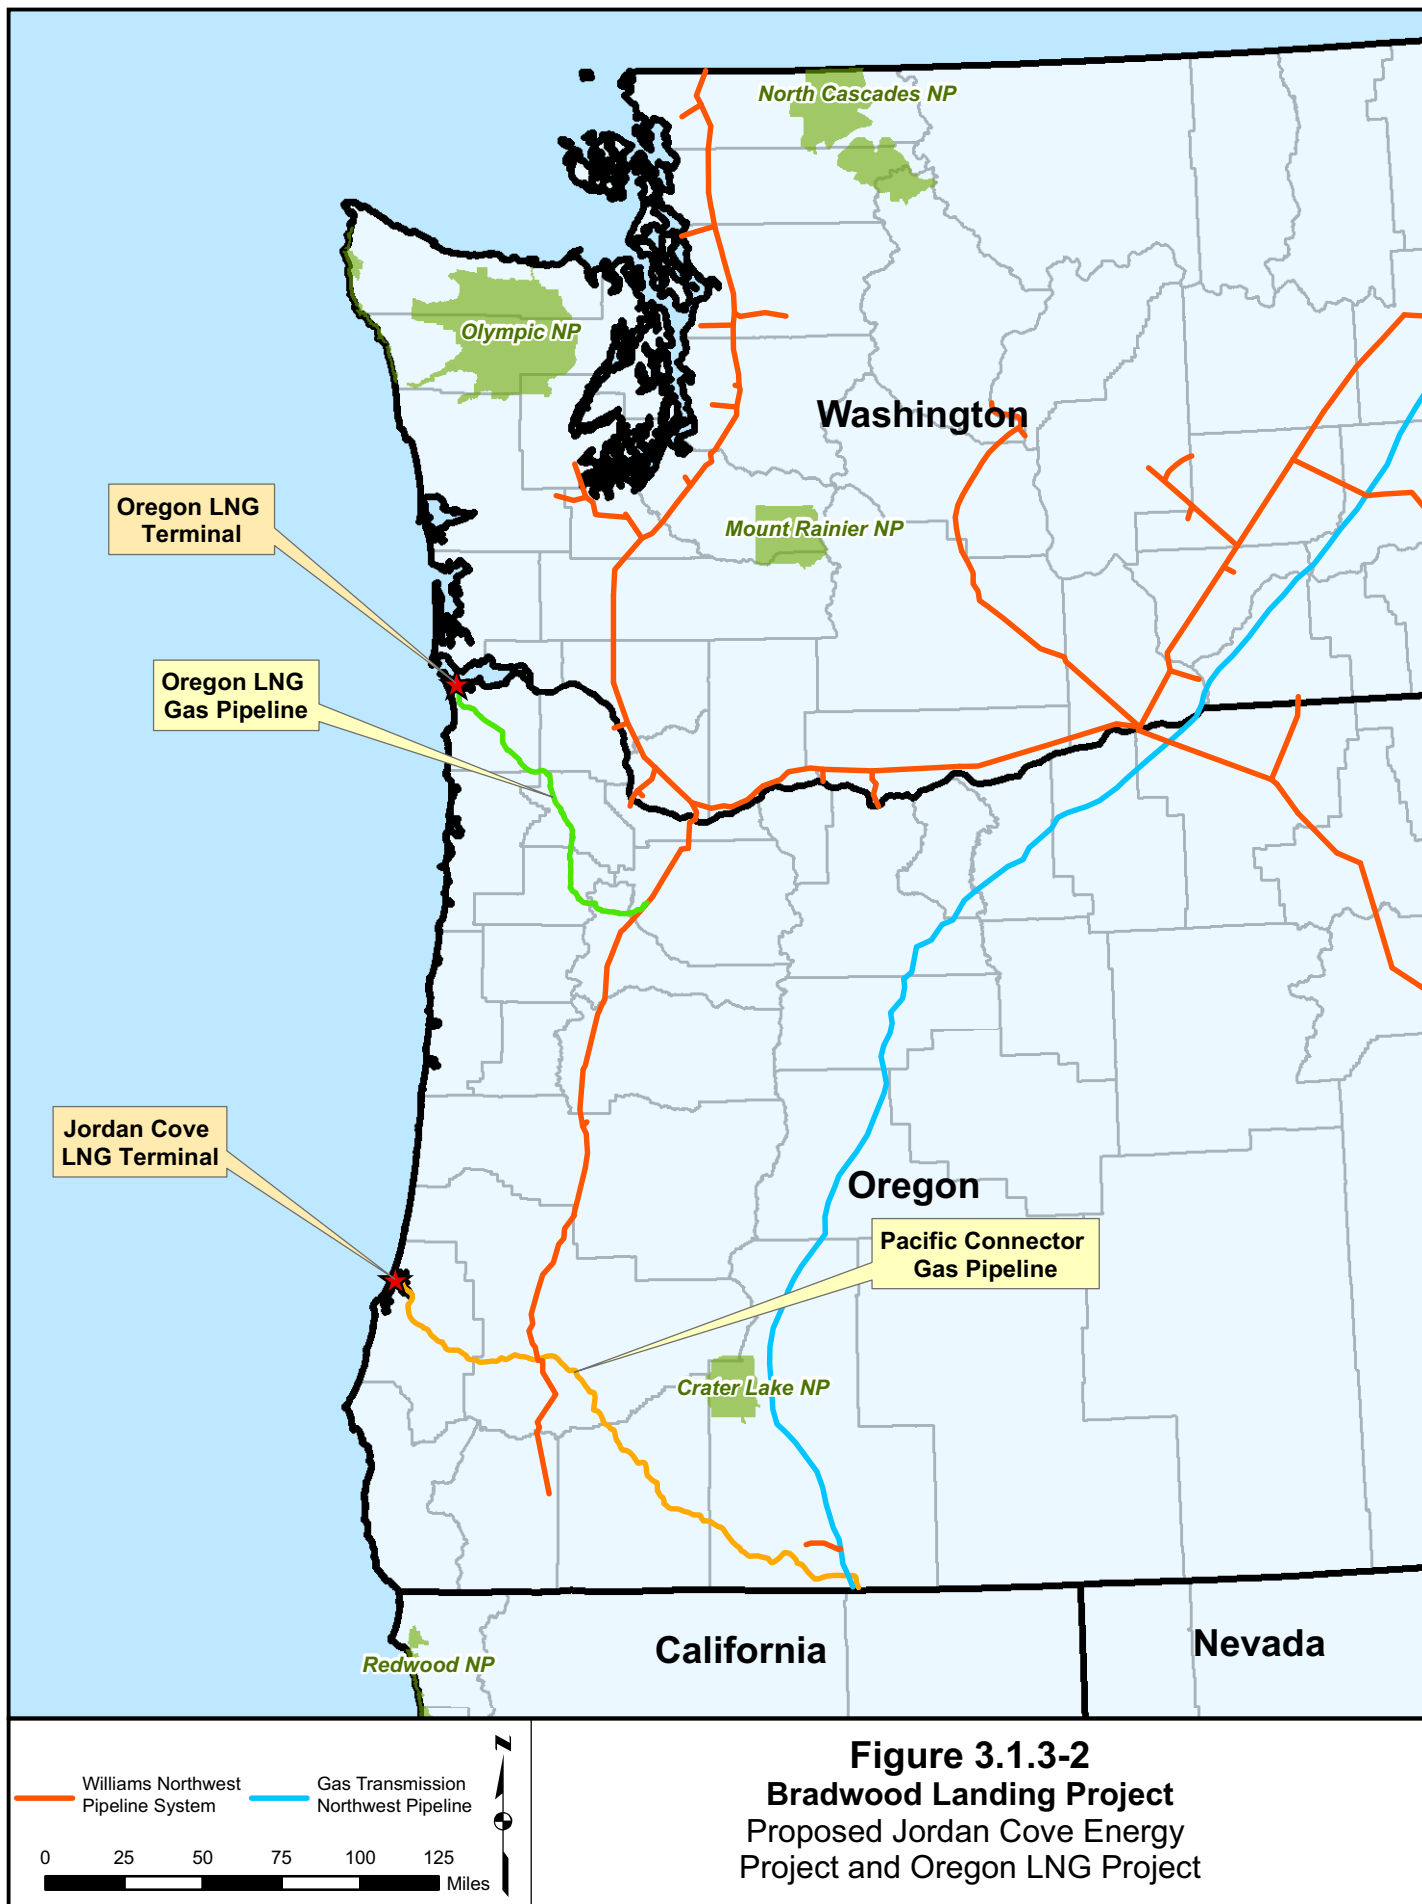

Figure 3.1.3-2
Bradwood Landing Project
 Proposed Jordan Cove Energy
 Project and Oregon LNG Project

The Oregon LNG terminal would be constructed within a 96-acre tract on the East Skipanon Peninsula, within the City of Warrenton, near the confluence of the Skipanon and Columbia Rivers, at about CRM 11 (see figure 3.1.3-3). The terminal site is owned by the State of Oregon, and leased to the Port of Astoria. Oregon LNG holds a 65-year sublease with the Port of Astoria. The Skipanon Peninsula was created by placement of sandy sediments dredged from adjacent waterways beginning in the 1920s. The site does not include any prime farmland. The surrounding land use is industrial and recreational. An 18-hole golf course was once planned for this area (Port of Astoria 2006a). The City of Warrenton recently rezoned the tract for water-dependent industrial use in order to allow for an LNG terminal at this location (Ramsayer 2005). The onshore portions of the parcel are zoned Water Dependent Industrial Shorelands 1-2, while the marine facilities are zoned Aquatic Development A-1.

The proposed Oregon LNG import terminal would have a single berth designed to handle about 100 LNG carriers per year, sized from about 70,000 m³ to 260,000 m³ in capacity. The berth would be located offshore in Young's Bay, adjacent to the Columbia River navigation channel, on submerged lands owned in fee by the ODSL, with current depths between 20 and 30 feet below mean lower low water (MLLW). Oregon LNG expects that construction of its berth and turning basin would require dredging of about 1,275,000 cubic yards of material within an 83-acre area to reach depths of about 45 to 50 feet required for the safe docking of LNG carriers. Oregon LNG indicated that its preferred alternatives for disposal of dredge materials would be in-water placement, including a combination of flow lane/scour hole placement and shallow open water placement. However, it has not specified the exact locations for dredge disposal.

Oregon LNG believes that its dock would qualify for the "wharf exception" under OSR 780.040(1), which would not require a lease from ODSL. The unloading platform at the berth would include three unloading arms and one vapor return arm. Construction of the dock and turning basin would affect about 138 acres.

Onshore facilities would include three 160,000 m³ full containment LNG storage tanks, vaporizers, and a sendout system with a peak capacity of 1.5 Bcfd of natural gas. Oregon LNG currently plans on using a combination of direct ambient air vaporizers and natural gas-fired heaters to regasify the LNG. Construction of the land based portion of the LNG import terminal would affect a total of about 70 acres.

Oregon LNG would install a new 36-inch-diameter 121-mile-long natural gas sendout pipeline to connect the LNG import terminal with the existing Williams Northwest system near Molalla, Oregon. About 30 percent of this pipeline route would follow existing rights-of-way, for roads, railroads, and power lines. Construction of the sendout pipeline would affect about 1,461 acres. In addition, Oregon LNG would install a 9.4-mile-long 24-inch-diameter lateral, in Washington County, Oregon, that would connect to existing Northwest Natural LDC system facilities. The lateral's maximum capacity would be 0.8 Bcfd. Aboveground facilities associated with the sendout pipeline would include a single electric-drive gas compressor station, located at about MP 51, where the Northwest Natural lateral would split off from the mainline. Oregon LNG indicated that it would be willing to transport its gas on the proposed Palomar pipeline, instead of building its own sendout pipeline, if the parties could reach a mutual agreement.

The closest residences are about 0.5 mile from the southern boundary of the Oregon LNG terminal. The facility would be visible from the hillside of the western portion of the City of Astoria and from the City of Warrenton. Oregon LNG indicated that there may be 14 structures located in close proximity to its proposed sendout pipeline.

Figure 3.1.3-3
Bradwood Landing Project
Photograph of Oregon LNG Looking Southeast

Oregon LNG has not yet filed all of its draft environmental resource reports, so we do not have complete information about the potential environmental impacts of the project on specific resources. Oregon LNG estimates that construction of its import terminal would affect about 21 acres of wetlands in total, including about 2.2 acres of mudflats, 18 acres of high marsh, and 1 acre of low marsh. About 11.5 miles of wetlands would be crossed by the proposed pipeline.

Calpine conducted a preliminary habitat category determination of the LNG terminal site in accordance with standards set by the ODFW (Ellis Ecological Services and CH2M Hill, 2005). Most of the parcel was proposed as Category 4 or 5 habitat, because it is degraded and does not provide important habitat for fish and wildlife. The shallow subtidal and mudflats, where the trestle and unloading pipeline from the berth would be located, were proposed as Category 2 habitat because these areas are important for salmonids. No Category 1 habitat was identified within the property. The area that would require dredging for the LNG carrier turning basin and berth was identified as deep subtidal habitat, proposed as Category 4.

Within the vicinity of the proposed LNG terminal, ship route, and pipeline facilities there are 34 federally listed threatened and endangered species. No federally listed threatened or endangered species were found during surveys of the upland portion of the proposed Oregon LNG terminal. The waterway for LNG marine traffic and the terminal berth would be located within the Lower Columbia River estuary. The estuary provides habitat for federally listed threatened and endangered fish species, including eight units of Pacific salmon and five segments of steelhead trout. In total, there are 15 federally listed threatened and endangered fish species in the project area. The waterway for LNG marine traffic is also a potential habitat for four species of federally listed threatened and endangered turtles, eight marine mammals, one invertebrate, and two plants. Four federally listed threatened and endangered bird species (brown pelican, northern spotted owl, marbled murrelet, and short-tailed albatross) were identified in the project area.

The proposed pipeline would cross about 699 acres of non-wetland forest, including portions of the Clatsop and Tillamook State Forests. About 549 acres of non-wetland agricultural land would be crossed by the pipeline, including some vineyards in the Willamette Valley.

The proposed pipeline would result in 192 waterbody crossings, which include 61 currently known perennial flow waterbodies, 39 currently known ephemeral flow waterbodies, and 27 currently known intermittent waterbodies. Oregon LNG indicated that it proposes to use HDDs at 20 waterbodies, including Adams Slough, Lewis and Clark River, Nehalem River, Tualatin River, Yamhill River, Willamette River, and Pudding River.

No archaeological sites were identified at the proposed Oregon LNG terminal, mainly because the terrestrial portion of this facility would be located on fill. Nine archaeological sites were found along surveyed portions of the pipeline route; of which eight require additional investigations to assess their NRHP eligibility.

In summary, the main environmental advantage of the Oregon LNG import terminal site would be its location downstream of the Astoria-Megler Bridge and the shorter distance up the Columbia River for LNG marine traffic. The main disadvantage, in comparison to the Bradwood Landing Project, would be environmental impacts associated with the additional length of the Oregon LNG sendout pipeline. In conclusion, the Oregon LNG terminal alternative does not appear to be environmentally superior to the Bradwood Landing Project.

Other Potential LNG Terminal Locations along the Columbia River

Tansy Point

Tansy Point is a low-lying headland located between the mouth of the Skipanon Waterway and Trestle Bay, 10 miles upriver from the mouth of the Columbia River, in Clatsop County, Oregon (see figures 3.1.3-4 and 3.1.3-5). The potential LNG terminal site is owned by the City of Warrenton and is leased to Warrenton Fiber Company. The company currently operates the 50-acre site as a log yard and wood processing facility. It is within the City of Warrenton's Water Dependent Industrial zoning district. Warrenton Fiber has been given a 5-year period to negotiate with the City for lease amendments, which would be required in order to construct an LNG facility on the site. While Warrenton Fiber is exploring the possibility of developing this site as an LNG terminal, no LNG development company or other financial backer has come forward, and no LNG import terminal proposal has been submitted to the FERC.

LNG carriers would have a relatively short transit up the navigation channel in the Columbia River to Tansy Point, and would not have to go under the Astoria-Megler Bridge. The site is currently equipped with a ship dock, and the river adjacent to the site is 43 feet deep. Therefore, no or minimal dredging would be required; however, the ship dock area would need to be rebuilt to meet the specific requirements for berthing and unloading LNG carriers.

The lower Columbia River is designated critical habitat for salmon. However, the designated salmon critical habitat near the mouth of the river is spread out over a larger area and fish in this part of the river generally spend less time in the habitat (NMFS, 2006a). This area is also EFH for groundfish and pelagic species, as well as salmon.

Based on National Wetlands Inventory (NWI) data, there are approximately 14 acres of wetlands present on the 50-acre Tansy Point site. These wetlands are confined to the southern half of the parcel. Assuming the LNG terminal would have a footprint of 45 acres and the terminal could be situated to minimize wetland impacts (i.e., the entire unused 5 acres would be wetland acres) development of the site for an LNG terminal would permanently impact about 9 acres of wetlands. No prime farmland is present at the site.

Some years ago, Tansy Point was the site of a terminal for a steamship that traveled between Warrenton and San Francisco. The topographic map for this area indicates ruins are present in the river adjacent to Tansy Point, and the Columbia River Maritime Museum in Astoria displays a record of the steam tug Firefly having sunk off Tansy Point in 1854. Therefore, cultural resources, including submerged remains of ship wrecks in the river, may be present at this location.

The berth for the Tansy Point site would be closer to the navigation channel compared to the other alternative sites along the Columbia River. This proximity could pose a higher risk of allisions between LNG carriers unloading their cargo and other ship traffic in the channel.

Of the potential alternative LNG terminal locations considered along the Columbia River, Tansy Point has the largest number of nearby residences and the area immediately southwest of the site is zoned for intermediate density residential use. Based on examination of aerial photographs, we estimate over 85 residential structures are present within 0.5 mile of the site. The proposed LNG terminal would also have visual impacts on residents of Warrenton.

Figure 3.1.3-4
Bradwood Landing Project
 Tansy Point

Figure 3.1.3-5
Bradwood Landing Project
Photograph of Tansy Point Looking West

Because there is no application before us, the FERC staff had to speculate about the length and location of a sendout pipeline for the Tansy Point LNG import terminal alternative. We assumed that the sendout pipeline would have to interconnect with the Williams Northwest pipeline, which is the closest existing interstate transportation system. In selecting the pipeline route, we made an effort to avoid populated areas without increasing the length of the pipeline by an unreasonable amount. The conceptual pipeline route would follow an existing power line corridor where possible. While it is standard practice to collocate pipelines with existing rights-of-way, we have not field verified that this route would be constructible for a natural gas pipeline. The sendout pipeline route we propose would be about 58 miles long. Its location is illustrated on figure 3.1.3-6.

In summary, the main environmental advantages of Tansy Point would be the short LNG marine transit distance, little or no dredging necessary for a turning basin in the Columbia River, and limited impacts on wetlands. Because the site is already being used for industrial purposes, development as an LNG terminal would have fewer impacts on wildlife habitats than if the land were previously undeveloped. Disadvantages include little separation of the berth from the navigation channel, population density around the site, and greater length for a sendout pipeline. In conclusion, the Tansy Point alternative LNG import terminal site is not clearly environmentally superior to the proposed Bradwood Landing Project.

Port Westward

The Port Westward alternative LNG terminal site is located on the south side of the Columbia River, opposite Oak Point, about 12 miles down river from Longview, Washington, in Columbia County, Oregon (see figures 3.1.3-7 and 3.1.3-8). The site is part of an economic zone managed by the Port of St. Helens. Port Westward LNG has an agreement with the Port of St. Helens to develop an LNG import facility within this zone. However, Port Westward LNG's request to the FERC to initiate our Pre-filing Review Process was not accepted because it could not demonstrate that it fully owned or controlled the entire parcel proposed for the LNG import terminal.

The proposed Port Westward LNG import terminal alternative site consists of two parcels totaling about 270 acres. The Thompson family owns a 145-acre wooded parcel fronting the Columbia River. The Port of St. Helens negotiated a 99-year lease agreement with the Thompson family to sublease this land (The Daily News, 2006a). Based on discussions between the FERC staff and representatives of Port Westward LNG, it appears that the terms of the lease agreement between the Thompson family and the Port of St. Helens are not ideal for the construction and operation of an LNG marine berth on that property.

The second parcel at the Port Westward site consists of agricultural land used for grazing cattle and a tree farm for pulp production, controlled by the Port of St. Helens. A farmstead is located on the property; however, the Port of St. Helens has an agreement with the residents for abandonment of the farm in the event the parcel is developed for industrial purposes. Surrounding land use is agricultural and industrial. We identified several residential structures east of the southeast corner of the site. However, depending on the exact placement and configuration of the 45-acre LNG terminal footprint within the site, these structures would likely be more than 0.5 mile away. No prime farmland is present at the Port Westward site.

The existing Beaver Power Plant, a natural gas and fuel oil fired facility operated by PGE, is located east of the proposed Port Westward LNG terminal site. PGE is currently constructing another power plant (fired by natural gas and coal) within the Port of St. Helens economic zone. Additional industrial facilities are planned for this area, including another new power plant and an ethanol production plant. An LNG terminal at the Port Westward site would have minor visual impacts, based on the relatively low population density of the surrounding area and the fact that the view has already been compromised by existing industrial infrastructure.

Power plants frequently use river water for cooling and discharge the warmed water back into the river, often with adverse impacts on aquatic resources. For example, there is a warm water discharge associated with operation of the Beaver Power Plant and the existing NPDES permit for this facility includes a schedule requiring PGE to conduct an evaluation and to implement controls to reduce effluent temperature. Further, water quality at this segment of the Columbia River is limited because of warm temperatures (ODEQ, 2004). “Waste heat” from one of the existing or planned power plants within the Port of St. Helens industrial zone could be a potential source of heat in a closed loop system to vaporize LNG for the proposed project. The use of waste heat could eliminate or reduce the need to burn natural gas in the LNG vaporization process. This would reduce air emissions and provide both environmental and economic benefits to the operation of the LNG terminal. It follows that the LNG terminal could also provide a source of “waste cold” that could be used to condense the steam used to produce electricity at one of the power plants. It is conceivable that an LNG terminal at this location could provide a source of cold water (or other liquid mixture) as part of a closed loop system between a power plant and the LNG vaporizers. The sharing of these processes could potentially provide environmental and economic benefits to both the LNG terminal and to the industrial facilities because it could eliminate or reduce air emissions associated with LNG vaporization at the LNG terminal and it could eliminate or reduce warm water discharges associated with the operation of the industrial facilities. A system similar to this is planned for Ingleside Energy Center LNG Project in Corpus Christi, Texas (see FERC Docket No. CP05-13-000). While environmental and economic advantages of such a system can be envisioned, conducting the technical design and commercial negotiations necessary to fully analyze the specific benefits and feasibility of a waste heat/cold system is outside the scope of this EIS.

NWI data indicates wetlands are present over the entire riverfront parcel, but no wetlands are present on the rest of the site. We assume the LNG terminal would be located back from the river with an extended pipe and trestle system to minimize impacts on wetlands and the slough. Assuming a 150-foot corridor for the pipe and trestle, 2.6 acres of wetlands would be permanently impacted, including 0.9 acre of forested/scrub-shrub wetlands, if the site was developed as an LNG import terminal. Without field wetland delineations, the extent of wetland impacts at this location is speculative, and the NWI data may underestimate potential wetland impacts at the Port Westward LNG terminal alternative site.

Using navigation charts with bathymetric data for the area, we estimate approximately 538,000 cubic yards of sediment would need to be dredged from the Columbia River bottom to create room for the ship berth and turning basin at Port Westward. Although this estimate is less than the volume that would be dredged at Bradwood Landing, a more detailed project-specific berth design and dredging plan would be required for Port Westward to allow for an accurate comparison of dredging between the two sites.

The Columbia River navigation channel up which the LNG marine traffic would have to transit some 54 miles is designated critical habitat and EFH for salmon. In addition to safety and security issues related to LNG marine traffic, the transit distance may increase the potential for impacts on aquatic and other resources. The wakes of LNG carriers may result in the stranding of juvenile fish at specific locations and contribute to river bank erosion (see sections 4.6.2.1 and 4.1.3.3, respectively). Port Westward is the only Columbia River LNG terminal alternative site located outside of the Oregon Coastal Zone.

The Port Westward site is located along the proposed Bradwood Landing pipeline route at about MP 18.0. The sendout pipeline would therefore follow the proposed route from the Port Westward site to the terminus north of Kelso, Washington for a total length of 18.3 miles. However, to achieve the project objective of interconnects at the Wauna Mill and Northwest Natural pipeline delivery points, a lateral pipeline to those locations would be necessary. This lateral would follow the same route as the proposed pipeline route for a total length of 14.3 miles. As such, the effective pipeline length for the Port Westward alternative would be 32.6. The lateral would be 24 inches in diameter to the Northwest Natural pipeline interconnect and then 4 inches in diameter to the Wauna Mill interconnect. For comparing impacts on wetlands we assume the construction right-of-way through wetland areas would be 75 feet for the 24-inch pipeline and 50 feet for the 4-inch pipeline. This compares to a construction right-of-way of 100 feet through wetlands for the proposed sendout pipeline and the sendout pipeline for the Tansy Point site alternative.

Because no NWI mapped wetlands are present along the proposed Bradwood Landing pipeline route between MPs 0.0 and 3.7, the same lineal feet of wetlands would be crossed by the Port Westward alternative pipeline as for the proposed sendout pipeline. However, because of the narrower construction right-of-way necessary for the smaller diameter pipeline, about 40 percent less wetlands would be impacted during construction. These impacts would be primarily temporary impacts as opposed to the impacts on the wetlands at the terminal site, which would be permanent. Six fewer waterbodies would be crossed by the Port Westward site alternative pipeline.

In summary, the Port Westward LNG terminal alternative would have some environmental advantages over the Bradwood Landing proposal. Port Westward would be located outside of the Oregon Coastal Zone, and upriver from the lower Columbia River estuary, which is considered critical habitat for some life stages of listed salmonids. It appears that somewhat less dredging would be necessary and fewer acres of wetlands would be impacted by construction of an LNG import terminal at Port Westward. The sendout pipeline from Port Westward would be slightly shorter than any of the other Columbia River LNG import terminal alternative sites. In addition, an LNG terminal at Port Westward could potentially take advantage of waste heat/waste cold exchanges with power plants within the Port of St. Helens economic zone.

However, there are also some disadvantages associated with the Port Westward location. First, the LNG marine traffic transit would be longer than for any of the other alternative sites along the lower Columbia River and 15 miles longer than for the proposed site. Second, it is unclear if the terms of the agreement between the Port of St. Helens and the Thompson family would allow for the economical construction and operation of an LNG marine berth on that property. Because of the longer LNG vessel transit and uncertainties over the lease agreement for the marine berth parcel, the Port Westward LNG terminal alternative is not significantly environmentally superior to the Bradwood Landing site.

3.1.4 LNG Terminal Alternatives Offshore of Oregon

Commentors have requested the study of offshore LNG terminal alternatives, in order to avoid many of the environmental issues and safety concerns associated with siting an LNG facility onshore. Offshore LNG import terminals located in federal waters fall under the jurisdiction of the MARAD and the Coast Guard (pursuant to the Deepwater Port Act of 1974, as amended by the Maritime Transportation Security Act of 2002).

This section presents a discussion of the available offshore LNG terminal technologies and strategies that were considered, presents an analysis of conditions on the Oregon coast and a comparison of conditions elsewhere, and provides the results of the quantitative analysis that was completed to

evaluate potential offshore alternatives, including a detailed evaluation of a hypothetical offshore alternative.

3.1.4.1 Offshore LNG Terminal Technologies and Strategies

Companies that have proposed to construct and operate offshore LNG import terminals have advanced various technologies and strategies for platform construction, LNG carrier mooring, LNG transfer and storage, vaporization, and sendout (LNG Express, 2003). These technologies/strategies include:

- offshore docking/onshore storage;
- fixed offshore terminals (GBS or platforms);
- transport/regasification vessels; or
- FSRUs.

The technologies evaluated for comparison with the proposed project are based on an analysis of weather conditions off the Oregon coast and basic system requirements for safely and efficiently offloading LNG. A discussion of conditions in Oregon, system requirements, and the technologies considered is included below.

Weather and Sea State

The weather in the Pacific Northwest is typical of a coastline along the eastern edge of a major ocean basin (ABSG, 2006). Weather patterns are controlled by the marine environment and modified by the boundary between land and sea. Winds along the coast are predominantly out of the south through westerly directions with associated ocean swell originating far offshore that frequently creates a high sea and quite long wave period.

An examination of data collected by National Data Buoy Center Buoy 6029 was completed to understand the feasibility of an offshore LNG receiving installation in Oregon. The data buoy is a 3-meter discus buoy that is owned and maintained by the National Data Buoy Center and located at 46°8'38" N, 124°30'42" W at the Columbia River Bar. The average, median, minimum and maximum values of the collected data are presented in table 3.1.4-1.

TABLE 3.1.4-1				
Data Collected by the National Data Buoy Center – Buoy 6029				
Data Category	Average	Median	Minimum	Maximum
Sustained Wind Speed (mph)	15.0	13.4	0.0	51.5
Gusting Speeds (mph)	19.0	17.9	0.0	67.1
Wave Height (feet)	9.8	8.5	2.6	43.6

Offshore marine terminal operations are not sustainable due to the extreme conditions experienced by the data buoy at the bar. For this data period, sustained winds were in excess of 20 miles per hour for over 27 percent of the readings. For an offshore installation engaged in the offloading of LNG, 20 mile per hour winds would present an operational metric valuable in illustrating the ability of an LNG carrier to operate safely in an unprotected marine environment. In addition, data indicates for the examined period that winds were in excess of 20 miles per hour for over 10 percent of the readings. Although it is recognized that the later part of the data collection period was characterized by seasonal adverse weather, the marginal terminal availability resultant from 27 percent availability (based on 20 mile per hour sustained wind limitation for offshore terminal/carrier operations) in addition to wave

heights greater than 20 feet over 10 percent of the time do not support safe marine operations to the extent that such an offshore terminal would be reliable and economically viable. Therefore, we conclude that offshore marine terminal operations are not preferable from an operational reliability standpoint and might not even be feasible.

The Pacific Ocean off the coast of Oregon is subject to rough weather and high sea states. The coastline in this area provides no islands, reefs, or prominent headlands for protection from rough seas or adverse weather (ABSG, 2006). The following information provides a comparison of conditions in Oregon with conditions for an existing location that has developed LNG infrastructure offshore (GOMEX) in the Gulf of Mexico and one proposed location in Massachusetts.

Wave height must be considered with the wave period to determine likely movements and associated forces such movements generate for a moored ship. Shorter wave periods are more manageable in terms of mooring design as they generally cause a larger ship to not respond with surge (forward and backward movement) as when longer wave periods exist. Figure 3.1.4-1 illustrates the comparison in recorded weather data for average wave height (ABSG, 2006).

The average sea condition for wave height offshore Oregon is between 5 and 10 feet (ABSG, 2006). Figure 3.1.4-2 provides a comparison of the average wave period for Oregon, Massachusetts, and the Gulf of Mexico. As figures 3.1.4-1 and 3.1.4-2 indicate, conditions are less favorable for an LNG import terminal off the Oregon coast compared to the other regions.

Offshore Terminal System Requirements

Success of an LNG facility offshore is dependent on the ability to transfer LNG from ship to facility without interruption once the LNG carrier is connected and is highly contingent on sea states encountered throughout the year (ABSG, 2006). Rough seas cause unfavorable ship motions, which can cause a ship to range against the mooring system and exceed limitations on piping systems and mooring lines, cause mass movement in the cargo tanks during discharge that could exceed the design load limitations for the containment system, and exceed design limits for operation of a regasification plant (if one is fitted to the ship).

LNG operations are more sensitive to sea conditions because of the specialized requirements for handling a very low temperature liquid (ABSG, 2006). LNG carriers do not normally have the capacity to discharge LNG as a gas. They normally pump liquid at about -263 °F to a facility that then regasifies the liquid for send-out. If a regasification plant is installed on the deck of an LNG carrier, cargo capacity of the LNG carrier is substantially reduced due to the weight of the equipment. Also, due to inherent space limitations on board the LNG carrier, regasification rates are considerably less than would normally be provided for a shore facility. (0.4 versus 1.5 Bcfd). Piping systems for unloading LNG must also be specially designed for extremely low temperatures and must have constrained movement envelopes to prevent oversteering and rupture. When LNG carriers discharge their cargo, the period during which the level of LNG inside the ship's LNG containment tanks is less than 70 percent and greater than 10 percent is critical. During this time, vessel movement (roll, pitch, and surge) causes waves of LNG within the tank. This is called "sloshing" and can seriously affect the tank containment system and must be avoided. For this reason, discharge must be completed within available windows of good weather and calm sea states. Finally, there are as yet no flexible lines that can be used for LNG transfer at sea. Too much movement will exceed limitations on the piping systems and mooring lines.

This information is for environmental review purposes only.

Technologies Considered

Offshore Docking/Onshore Storage

Where deepwater access to a coastal port or harbor is unavailable, LNG can be transported to onshore storage tanks from ships using specially designed cryogenic pipelines. Such facilities enable LNG carriers to berth and transfer their LNG cargo to the cryogenic pipeline at docking facilities in offshore areas where natural water depths exceed 40 feet. Although feasible, a number of technical factors related to transporting LNG in a pipeline place limits on the practical maximum length of such a pipeline. This approach has been used at the existing Cove Point LNG terminal where the ship docking/unloading platform is located in the Chesapeake Bay about 1 mile from the shoreline. Similar facilities have been proposed for the Irving Oil LNG site in New Brunswick, Canada, and the Keltic Petrochemicals LNG and Bear Head LNG facilities in Nova Scotia, Canada. No such facility has been proposed for the West Coast.

While it would be possible to transfer LNG to shore through a cryogenic pipeline from an offshore docking structure, such a design would still require locating LNG storage tanks and process facilities at an onshore location, therefore resulting in similar environmental impacts as an onshore LNG import terminal, in addition to the disadvantages associated with an offshore docking structure and pipeline. Because of severe winter weather conditions and significant wave heights along the Oregon and Washington coasts (ABSG Consulting Inc. (ABSG), 2006), we did not identify a site where the use of this approach appeared practical for this project.

Fixed Offshore Terminals

There are basically two different types of fixed structures that can be used as an offshore LNG import terminal, either a GBS located directly on the seafloor or a pile-based platform. A GBS would contain LNG storage tanks and vaporizers on a platform with foundations directly on the seafloor. LNG could be offloaded from conventional LNG carriers, placed in the storage tanks within the GBS, and then vaporized for delivery as natural gas to the onshore market via an undersea pipeline. A GBS is only feasible in areas of relatively shallow water, where depths range between 45 and 100 feet. Given the costs associated with constructing and operating a GBS, it appears that these facilities are economical for projects with relatively large LNG storage (e.g., 250,000 to 330,000 m³) and large natural gas sendout volumes (e.g., 800 to 2,000 MMcfd). Another limitation would be the articulation of the unloading arms between the GBS and a docked LNG carrier, whose movement would be affected by high winds and large waves.

Chevron received approval from the Coast Guard to build an LNG import terminal in the Gulf of Mexico (the Port Pelican Project) using a GBS, but has formally put the project on hold indefinitely and license rescission is expected. The recently abandoned Terminal GNL Mar Adentro de Baja proposed by Chevron as an LNG terminal off the western coast of Baja, Mexico also would have used a GBS at a depth of about 65 feet.

Another strategy using a fixed offshore terminal involves constructing offshore platforms on piles or converting existing offshore platforms to LNG use. Such fixed-tower structures, could be located in deeper water than a GBS. The platforms could be fitted with docking, unloading, storage, and vaporization equipment. As with a GBS, LNG could be unloaded from a conventional LNG carrier, vaporized at the platform, and sent as natural gas to the onshore market via an undersea pipeline. A fixed platform would have limited space for LNG storage, and would need calm seas or protection from the elements (such as being located on the lee side of an island) to allow for safe LNG carrier docking.

Depending on the specific design, offshore platforms may or may not include LNG storage facilities. The Clearwater Port proposed by NorthernStar Natural Gas, Inc. would retrofit an existing offshore platform off the coast of Ventura County, California as an LNG import terminal, but would not have any LNG storage on the platform, and instead would use underground gas storage onshore to compensate for irregular deliveries of gas (LNG Express, 2005).

Transport/Regasification Vessels

Several companies have proposed the installation of vaporization equipment on conventional LNG carrier ships, which would be called transport and regasification vessels. These ships would be able to dock at a floating unloading buoy and riser system where LNG could be vaporized onboard the LNG carrier and injected directly into offshore pipelines that interconnect with onshore natural gas transmission systems. The vaporization equipment located on the ships would use technology that is similar to land-based LNG terminals.

Because LNG is vaporized on board the LNG carrier, this approach eliminates the need for fixed LNG storage. Some of the tradeoffs of this approach are that it requires a dedicated LNG fleet with vaporization equipment on all of the vessels. Additionally, it takes 6 to 10 days to unload a ship at a maximum design rate of about 0.5 Bcfd.

In March 2005, the first project using this strategy began operation, and is the only existing offshore LNG import terminal of any type in North America. Excelsite's Gulf Gateway Deepwater Port includes a submerged turret loading system and about 8 miles of 20-inch-diameter pipeline that connects to two existing subsea pipelines located about 116 miles south of Cameron, Louisiana (LNG Express, 2002 and 2003). Excelsite ordered three LNG carriers to be constructed to include onboard vaporization equipment. One of these ships is now in service and is delivering natural gas to the United States. Excelsite has indicated that it is exploring the installation of another offshore buoy and regasification vessel system to serve offshore northern California, known as the Pacific Gateway Project (see section 3.1.3.3).

As described above in section 3.1.3.3, Woodside has proposed a project using a similar technology at an offshore location 22 miles southwest of Los Angeles, California. The Ocean Way LNG Terminal Project would consist of a ship mooring facility with a flexible connection to an underwater natural gas pipeline that would come onshore at the Los Angeles International Airport and connect to the Southern California Gas Company delivery network (CEC, 2007b).

Floating, Storage, and Regasification Units

FSRUs are another approach being considered for importing LNG into the United States from offshore terminals. In essence, an FSRU would be an oversized LNG carrier vessel that is outfitted with LNG vaporizers and docking/unloading equipment. The FSRU would be up to 1,200 feet long, 180 to 215 feet wide, and would be able to store between 250,000 and 350,000 m³ of LNG; over twice the capacity of typical LNG carriers that are currently available. These units would be anchored offshore of the proposed market area where conventional LNG carriers could dock next to and unload LNG to the FSRU. After the LNG is unloaded, it could be vaporized and the natural gas could be transported to onshore markets through an undersea pipeline. Depending on the vaporizers and the size of the pipeline, these units could have a natural gas sendout capacity ranging from 700 to 1,500 MMcfd. BHP Billiton's Cabrillo Port Project, to be located about 14 miles off the southern California Coast, proposes to use an FSRU. The Moss-Marine LNG terminal proposed off the coast of Baja, California would also use an FSRU, as would the Broadwater LNG Project proposed for the Long Island Sound between Connecticut and New York (see FERC Docket No. CP06-54-000, et al.).

3.1.4.2 Application of Offshore Technologies to the Proposed Project

Relative to conditions in Oregon, NorthernStar evaluated four offshore technologies (GBS, fixed platform, transport/regasification vessels, and FSRU) to determine if they were viable alternatives to the Bradwood Landing Project and could meet the project objectives as stated in section 1.1. These technologies were compared to the proposed project and evaluated relative to existing offshore conditions near Astoria, Oregon. This analysis was based to a large degree on a study performed by ABSG (ABSG, 2006). The four offshore technologies are summarized and compared to the proposed onshore project in table 3.1.4-2 and are discussed in greater detail below.

TABLE 3.1.4-2 Assessment and Comparison of Offshore Technology to the Proposed Project					
	GBS	Fixed Platform	Transport/Regasification Vessels	FSRU	Proposed Project
Performance in rough seas/weather	Poor	Poor	Good	Poor	NA
Terminal Cost (\$ billion) ^a	1.8	1.3	2.5 ^b	1.3	0.7
Pipeline Cost (\$ billion) ^a	0.3	0.3	0.3	0.3	0.1
Environmental Impacts Terminal	Low	Low	Low	Low	Low
Environmental Impacts Pipeline	Medium	Medium	Medium	Medium	Low
^a Assumes a natural gas sendout capacity of 1.5 Bcfd. ^b Cost includes purchase of specialized LNG transport and regasification vessels as well as a mooring/unloading system. NA Not Applicable					

The Pacific Ocean off the coast of Oregon is subject to rough weather and high sea states. ABSG compared three wave characteristics (i.e., maximum significant wave heights, average significant wave heights, and average wave periods) for Oregon, the Gulf of Mexico, and Massachusetts. Relative to all three of these wave characteristics, conditions are less favorable for an LNG import terminal off the Oregon coast compared to the other regions. The coastline in this area provides no islands, reefs, or prominent headlands for protection from rough seas or adverse weather (ABSG, 2006).

Of the four offshore technologies evaluated, the transport/regasification vessel alternative (Excelerate's Energy Bridge technology) is the only one that would not be affected by rough sea conditions. For the other three technologies, LNG carriers would be able to unload only during calm sea conditions, thus leading to substantial operational limitations. While transport/regasification vessels would perform well in rough seas and weather, they generally have lower regasification rates (e.g., 0.5 Bcfd), require specially modified ships, and have no storage capabilities. This alternative would be the most expensive offshore option (assuming four buoys and eight ships to provide a comparable capacity and uninterrupted supply), and it would be nearly four times the cost of the proposed onshore terminal. The other offshore terminal alternatives would cost at least twice as much as the proposed onshore terminal.

Locating an LNG terminal on an offshore fixed platform may have impacts on the ocean bottom and affect aquatic habitat. A GBS would need to be constructed onshore and then towed out to sea. The onshore graving dock¹ facility for constructing the GBS would have associated environmental impacts

¹ A graving dock consists of an excavated area adjacent to a deepwater channel that is used to fabricate the GBS. When the GBS is complete, the graving dock is flooded, allowing the GBS to float and be moved into the adjacent channel, from which it can then be towed to the offshore LNG terminal location.

that the other offshore technologies would not have. These might include impacts on terrestrial wetlands, wildlife and vegetation, and cultural resources.

The kind of vaporizers used at an offshore LNG terminal would influence the kind of impacts the facility may have on the aquatic environment. For example, ORVs that use seawater may entrap or entrain small aquatic species and ichthyoplankton during intake. Further, once the water is run through the ORVs, it would be cooled, with the discharge changing sea temperature and perhaps impacting marine life and water quality. ORVs were proposed for the Port Pelican and Gulf Landing offshore LNG terminal projects in the Gulf of Mexico. However, neither of these projects is moving forward; as indicated above, the Port Pelican Project has been put on hold indefinitely, and Shell recently announced it was discontinuing plans for the Gulf Landing terminal off the shore of Louisiana (Reuters, 2007).

To further evaluate the feasibility of an offshore alternative, NorthernStar completed an evaluation of a hypothetical offshore facility. The location chosen for the offshore LNG terminal alternative is a point southwest of the mouth of the Columbia River, 10 miles offshore of Clatsop Plains, Oregon (see figure 3.1.4-3). NorthernStar selected this offshore alternative location after considering the most feasible route for an undersea pipeline to connect to onshore facilities. Water depths at the offshore terminal alternative location would be about 250 feet. This site could accommodate most offshore LNG terminal technologies, but not a GBS, which would need to be located in more shallow water. In order for a GBS to be used for an offshore LNG import terminal alternative, it would have to be within 2 miles of the Oregon shore.

Assuming the use of NorthernStar's hypothetical offshore LNG import terminal alternative location, the corresponding sendout pipeline would cross beneath the sea for 10 miles to shore. It would then have to continue as an underground pipeline onshore heading eastward for at least 40 additional miles, compared to the proposed project, to reach the existing interstate pipeline system of Williams Northwest. Such a pipeline would require a compressor station along the route and would cost more than twice as much as the proposed sendout pipeline for the Bradwood Landing Project. Environmental impacts associated with the offshore portion of the pipeline route would be most likely to occur during construction and could include:

- direct disturbance of the seafloor and associated habitats;
- increased turbidity and sedimentation affecting water quality and marine biota;
- disturbance of sensitive marine mammals, birds, and fish;
- disruptions to shipping, fishing, and recreational activities;
- air emissions from construction equipment; and
- disturbance of archaeological resources.

The types of environmental impacts associated with the onshore portion of the sendout pipeline for an offshore LNG terminal alternative would be similar to those associated with the pipeline for the proposed project. However, the impacts would be roughly twice as great due to the greater length.

An offshore LNG import terminal alternative would avoid some of the environmental impacts of the proposed Bradwood Landing Project, such as effects associated LNG marine traffic up the Columbia River, critical salmon habitat in the river, nearby population and visual effects, and impacts on terrestrial resources, including wetlands. However, based on our review of the analysis conducted by ABSG and NorthernStar, we do not consider an LNG terminal off the coast of Oregon to be a viable alternative to the proposed project because of the rough sea and weather conditions and the additional environmental impacts associated with the longer sendout pipeline.

3.1.5 Regional LNG Import Terminal Site Alternatives

The examination of alternative sites for an LNG import terminal involved a comprehensive process that considered environmental, engineering, economic, safety, and regulatory factors within a regional context. The first step included determining the most suitable area for an LNG terminal based on the stated purpose of the project of providing natural gas to customers in the Pacific Northwest. That limited the search for alternative sites to areas of Washington and Oregon that would be accessible for LNG marine traffic. The second step included the identification of ports within this region that would be capable of accommodating LNG carriers. The third step evaluated specific locations at qualified ports that had proper zoning and land necessary to support LNG carrier docking, storage, and regasification facilities of an onshore import terminal. As discussed above in section 3.1.4, offshore alternatives do not currently appear economically, technically, or environmentally feasible or reasonable in the Pacific Northwest. As such, only onshore terminal site alternatives were considered in more detail, below.

3.1.5.1 Regional Review

As discussed in section 1.1, there is a growing demand for natural gas in the Pacific Northwest. We considered alternative LNG terminal sites along the coast of Washington and Oregon that would be accessible to LNG carriers and within a reasonable distance of an interstate pipeline system.

3.1.5.2 Port Area/Waterway Review

Ships that are presently used to transport LNG typically have capacities of up to 154,000 m³. The larger ships are from 950 to 1,000 feet long with typical drafts up to 39 feet. To ensure that the LNG carriers do not easily or frequently run aground, up to an additional 2 feet of water is desirable under the keel. This means that LNG carriers will typically only access areas with depths of at least 40 feet. Although dredging in shallow water areas could provide access for LNG carriers, the dredging required in undeveloped ports or areas without deepwater channel access would be cost prohibitive and would most likely result in significant environmental impacts. Consequently, our analysis of alternative LNG terminal sites was limited to existing deepwater coastal ports that could readily accommodate LNG carriers without dredging or without significantly more dredging than would be required for use of the proposed site. We identified Puget Sound (Washington), Grays Harbor (Washington), Coos Bay (Oregon), and the Columbia River (Washington/Oregon) as appropriate areas for an LNG import terminal. Coos Bay was previously discussed in section 3.1.3.4 under the proposed Jordan Cove Energy Project alternative.

3.1.5.3 Site Review

In addition to providing reasonable access to the Pacific Northwest market from sites with depths that would allow LNG carrier access, coastal port areas or waterways were evaluated for the availability of sites suitable for developing an LNG terminal. To narrow the range and fully evaluate project alternatives, we developed criteria to assist in identifying and comparing specific sites for consideration as LNG terminal alternatives. The review process included the examination of required and favorable review criteria.

Required criteria included regulatory specifications regarding LNG facility layout and safety siting factors that are required to be met for the project to be feasible. If not met, the required criteria served to exclude a site from further consideration. Required criteria included:

- **Thermal Exclusion/Vapor Dispersion Zone** (49 CFR 193.2057 and 193.2059) – Thermal exclusion and vapor dispersion zones must be established in accordance with

NFPA 59A. Based on the proposed project design, we have assumed a representative exclusion zone with a radius of 1,000 feet from the center of the LNG storage tank.

- **Airports** (49 CFR 193.2155(b)) – LNG storage tanks must not be located within a horizontal distance of 1 mile from the ends of a runway, or 0.25 mile from the nearest point of a runway, whichever is longer. The height of LNG structures in the vicinity of an airport must also comply with Federal Aviation Administration requirements.
- **LNG Waterfront Handling Requirements** (33 CFR 127.105) – Waterfront facilities where LNG is handled must comply with Coast Guard regulations pertaining to layout and spacing of the marine transfer area. These regulations require that each LNG loading flange be located at least 985 feet from general public or railway bridges crossing navigable waterways or entrances to any tunnel under navigable waterways.

We evaluated alternative LNG terminal sites to determine if environmentally preferable alternatives to the proposed site exist. Favorable review criteria, although not absolute alternative requirements, were applied to identify those sites that would be reasonable and most likely to provide some environmental advantage over the proposed project. For example, criteria were identified that would specifically improve upon some aspects of the Bradwood Landing Project such as those associated with impacts on aquatic resources. Favorable criteria were not intended to strictly eliminate the evaluation of certain sites. Some sites were selected for further analysis because they satisfied a majority, but not all, of the favorable criteria. Given the limited availability of suitable sized parcels in areas with deepwater access, it was not possible to locate an alternative that met all of the favorable review criteria. Favorable criteria included:

- **Population Centers/Residences** – We made an effort to identify alternative LNG terminal sites in areas that are not in close proximity to population centers and/or residences. Similarly, alternative LNG terminal sites were considered preferable if the location did not require LNG carriers to transit near residentially and commercially developed shorelines. In addition to avoiding potential conflicts with existing land uses, application of this favorable criterion would ideally avoid conflicts regarding perceived safety issues related to transport and storage of LNG.
- **LNG Terminal Footprint** – Based on the proposed design and the need to contain the thermal exclusion zone, a waterfront site of about 45 acres (the size of the proposed terminal site) would be preferred to accommodate the proposed configuration of the LNG unloading, storage, and sendout facilities. An ideal waterfront site available for development would include an area in excess of the exclusion zone that would provide an additional buffer from development.
- **Dredging Required** – Given the environmental impacts associated with significant dredging projects, we considered the amount of dredging necessary to provide access to LNG carrier access one of the alternative site review criteria. Areas requiring minimal dredging to develop and maintain a ship berth and a shipping channel of sufficient depth for the LNG carriers were considered more favorable than those areas requiring more substantial dredging. In addition to avoiding impacts on water quality and aquatic resources, minimal dredging requirements provide the added benefit of reducing costs associated with disposal of dredged material.
- **Parcel Availability** – One of the greatest challenges of siting an LNG facility is finding suitable property that is available for industrial development. Availability is critical since

section 3 of the NGA does not provide the project proponent the authority of eminent domain in acquiring property for the LNG terminal project facilities. In some cases, a site may possess the size required for an LNG terminal but the owner is unwilling to sell or has placed unacceptable conditions on the acquisition of the site.

- **Existing Land Use** – Areas previously disturbed or cleared for industrial or commercial activities were preferred over undisturbed areas (greenfield sites) when identifying alternative LNG terminal sites. Additionally, we preferred sites where existing land use zoning, coastal zone management guidelines, or development plans were consistent with an LNG import terminal. For example, although we considered all areas with deepwater access, areas outside of designated ports were generally determined to be less preferable than areas within designated ports. Those sites in areas consistent with existing land uses were considered the most practical alternatives to the proposed site.
- **Sendout Pipeline Factors** – We considered sites proximal to existing interstate pipeline systems that could accommodate the proposed volume throughput more favorably than sites farther from existing pipelines. In addition, we favored pipeline routes that would cross fewer waterbodies and impact less wetlands. On top of the additional costs and environmental impacts, longer pipelines would likely directly and indirectly affect more landowners/residences.
- **Navigational Suitability** – Sites that offer minimal disturbances to existing shipping and allow for good access by LNG carriers were considered a favorable selection criterion. We also considered bridge transit along the navigation channel in our site analysis, since LNG carriers require a vertical clearance of at least 135 feet and horizontal clearance of not less than 165 feet.
- **Various Environmental Factors** – Environmental factors that were considered in our site selection included: minimizing wetland disturbance and preferring sites in uplands; avoiding areas that would conflict with recreational activities; and selecting sites where the LNG storage tank would have a minimal impact on the viewshed from roadways and surrounding communities.
- **Special Interest Areas** – We considered favorably those sites that avoided conflicts with special interest areas such as state or national parks and marine sanctuaries. When applying this criterion, we considered potential conflicts with special interest areas from either an LNG terminal or its associated sendout pipeline.

The sites discussed below include reasonable alternatives to the terminal location proposed by NorthernStar. We have also included a discussion of alternative LNG terminal sites that were brought up during project scoping. Figure 3.1.5-1 depicts the locations of these sites.

Puget Sound Area

During the public scoping process, we received comments that the Puget Sound area would be more suitable for an LNG import terminal than the Columbia River. We considered two locations along Puget Sound - Cherry Point and Port Angeles. As described below, both locations were eliminated before specific sites were identified.

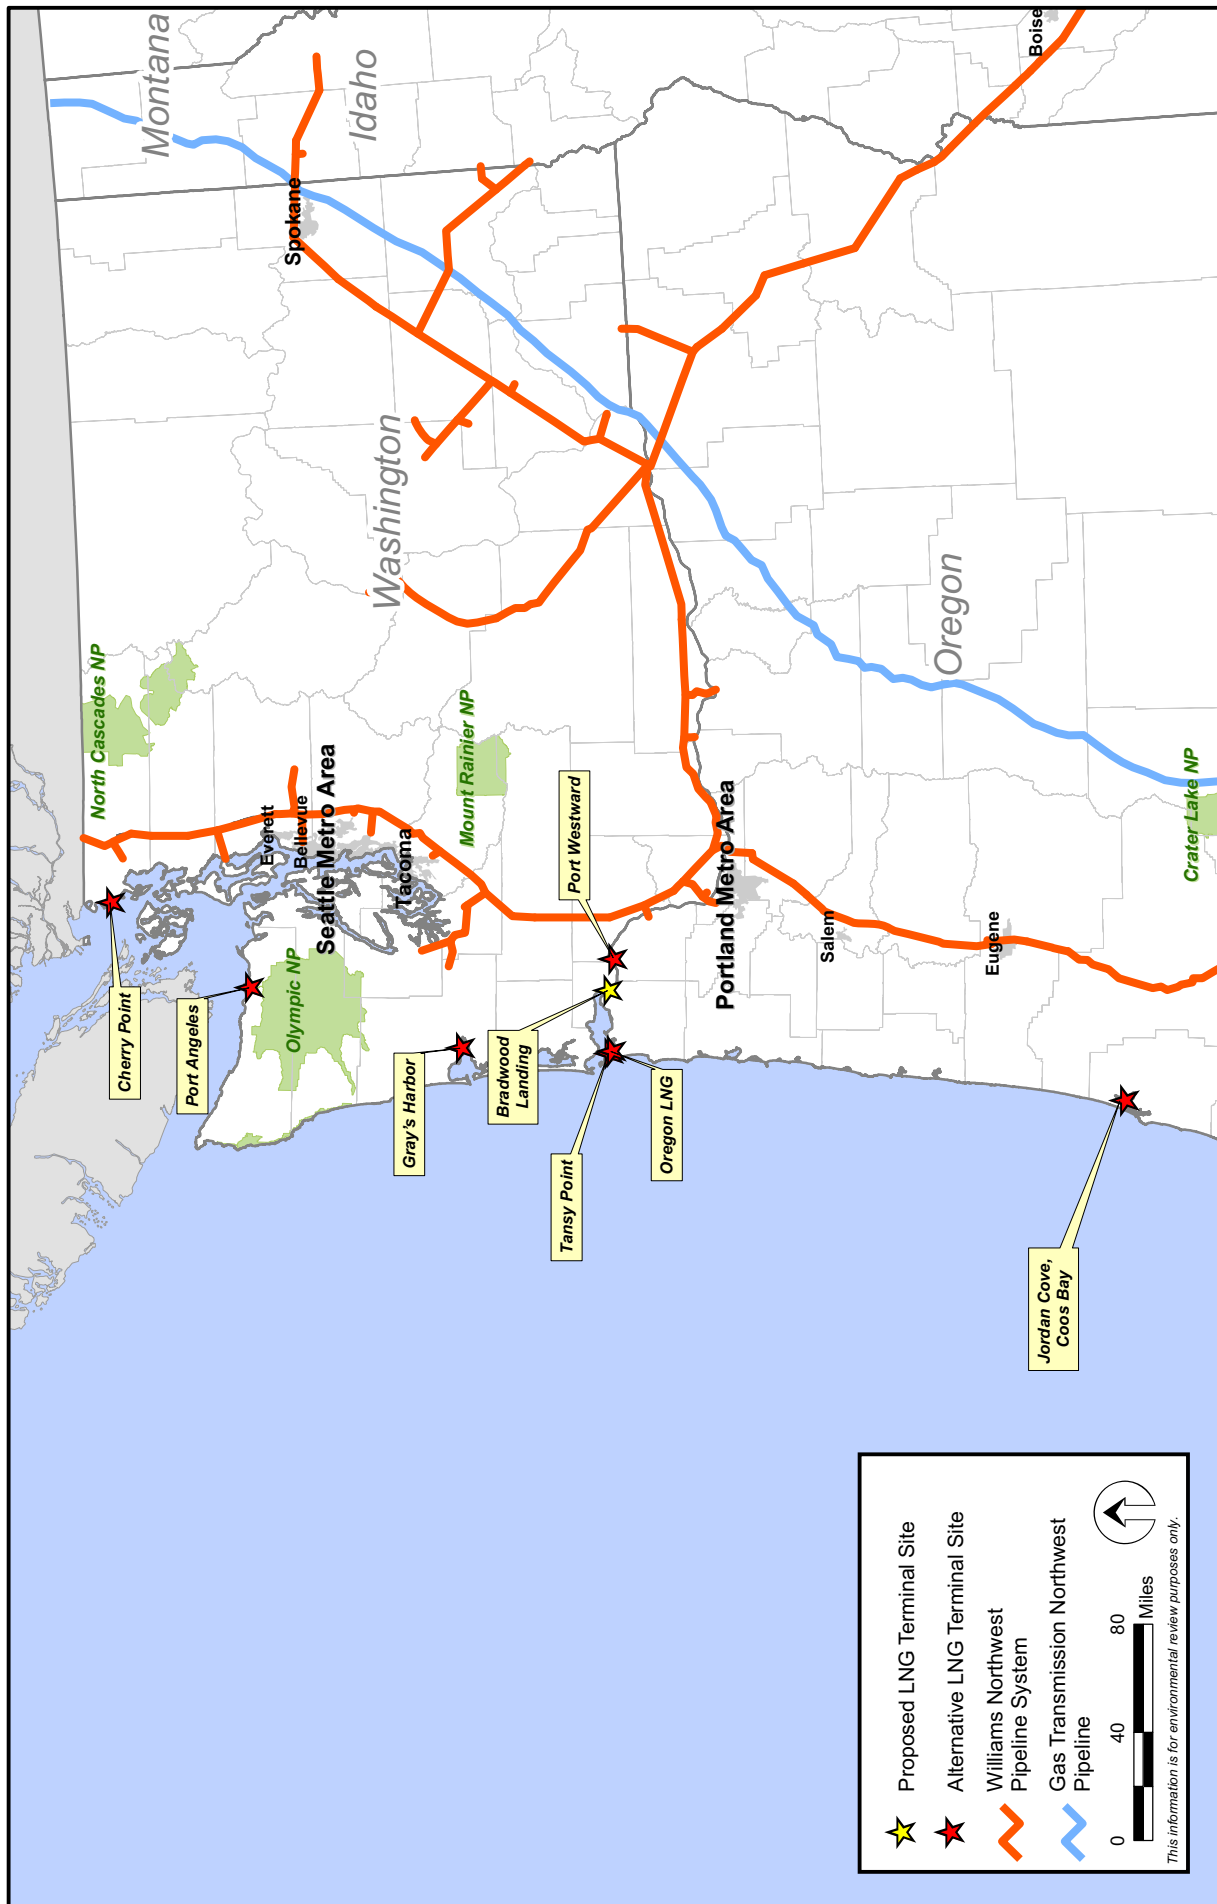

Figure 3.1.5-1
Bradwood Landing Project
 LNG Import Terminal Alternatives in Washington and Oregon

Cherry Point

The Cherry Point Urban Growth Area (UGA) extends along the coast of Georgia Strait from just south of Birch Bay State Park to the northern boundary of the Lummi Reservation in Whatcom County, Washington. The County has designated the Cherry Point UGA for industrial development and it is currently the site of two oil refineries and an aluminum smelter. A proposed 1,100-acre bulk commodities shipping port is also planned for the Cherry Point UGA. Approximately 1,800 acres (the equivalent of two sites with piers) remain for additional major industrial development with deepwater shipping access (Whatcom County, 2005). The Williams Northwest pipeline could be accessed approximately 18 miles east of the Cherry Point industrial area.

According to a recent newspaper article in the Bellingham Herald (Bellingham, 2007), the Lummi Nation, in partnership with Mercator Energy LLC, has been exploring the possibility of locating an LNG import terminal at Cherry Point since 2003. The Lummi Reservation is located adjacent and south of the Cherry Point UGA; however, the newspaper article indicated that new land would be acquired by the tribe for the terminal and would then be converted to tribal trust land. At this time the project is considered dormant by the tribe, because property for the proposed terminal has not yet been acquired.

At first glance, the Cherry Point location appears to be suitable for an LNG import terminal; however, the Washington Commissioner of Public Lands signed a Withdrawal Order creating the Cherry Point State Aquatic Reserve (CPSAR) on August 1, 2000. The land was set aside to protect various aquatic resources, including the declining stocks of Pacific herring in the area as well as the local crab fishery and migratory habitats for waterbirds and marine mammals. The CPSAR extends from the southern boundary of Birch Bay State Park along the coast to the northern boundary of the Lummi Reservation (roughly protecting the area from 0 MLLW to -70 MLLW).

The development of a specific management plan by the Washington State Department of Natural Resources (WDNR) for the CPSAR will not likely be finalized until late 2007 or early 2008. Interim guidelines for managing the CPSAR prohibit the development of any new in-water structures within the CPSAR (e.g., dock or pier construction). According to the WDNR, interim development restrictions for this aquatic reserve are consistent with Whatcom County's Shoreline Management Plan, which also prohibits development of new docks or piers in this area. Because of the restrictions on development associated with the CPSAR, the Cherry Point location was eliminated from further consideration for an LNG terminal site alternative.

Port Angeles

Port Angeles is a small city of around 20,000 people located on the south shore of the Strait of Juan de Fuca in Clallam County, Washington. It is the West Coast's northernmost deepwater port. The harbor is home to a top-side ship repair facility, a luxury yacht builder, and the terminal for the ferry to Victoria, British Columbia. The waterfront area is fully developed. The Clallam County Economic Development Council lists a number of large industrial parcels available for development, including 112 acres owned by the Port of Port Angeles; however, none of these parcels has waterfront access (Clallam County Economic Development Council, 2006).

We determined there was no available industrial use land with deepwater port access in the Port Angeles area that could be considered for an LNG terminal site alternative and therefore did not further consider this alternative.

Grays Harbor

Located on Washington's coast about 40 miles north of the mouth of the Columbia River, Grays Harbor includes a deepwater shipping port used by a variety of industrial tenants. Within the Port of Grays Harbor, we identified one site (located at Terminal 3) that could potentially accommodate an LNG terminal and that is available for sale or long-term lease. The Port of Grays Harbor Terminal 3 is a marine industrial site located in the City of Hoquiam less than 1.5 hours by ship from open sea and 1 hour by vehicle from Olympia, Washington. The site consists of 150 level acres with good drainage. A 600-foot by 120-foot deepwater marine terminal, with 38 to 40 foot depths, already exists adjacent to the site. The site is owned by the Port of Grays Harbor and is zoned for heavy industrial use. Electrical service, industrial water, and wastewater treatment facilities are available on site (Grays Harbor Economic Development Council, 2005).

The site is just east of Bowerman Field, a small general aviation airport with a 5,000-foot paved runway. According to 49 CFR 193.2155(b), LNG storage tanks must not be located within a horizontal distance of 1 mile from the ends of an airport runway, or 0.25 mile from the nearest point of a runway, whichever is longer. Because the entire site would be located within 1 mile of the east end of Bowerman Field runway, this site was eliminated from further consideration. We are not aware of other properties within Grays Harbor that would potentially be suitable for an LNG terminal.

Columbia River

Three alternative LNG terminal sites were identified along the Columbia River (Tansy Point, Oregon LNG, and Port Westward) in addition to the proposed Bradwood Landing Project. These alternative LNG import terminal locations are discussed above in section 3.1.3.4. In conclusion, none of the other alternative locations for an LNG import terminal along the Columbia River appear to be clearly environmentally superior to the Bradwood Landing Project. Other LNG import terminals in Oregon would not be considered mutually exclusive. If they do not cause significant environmental impacts, and the market could support them, multiple LNG import terminals could be authorized to serve a growing demand for natural gas in the Pacific Northwest.

3.1.6 Bradwood Landing LNG Terminal Design Alternatives

3.1.6.1 Alternative LNG Storage Tank Designs

The most visible component of an LNG import terminal facility is typically the LNG storage tanks. We evaluated three alternative LNG tank designs relative to their potential visual impacts and other environmental impacts, engineering/design feasibility, and costs. These three alternatives are summarized below.

Conventional at-grade LNG storage tanks would have the highest profile and thus the greatest visual impacts, particularly on sensitive viewers located on Puget Island. However, these impacts would be mitigated by use of appropriate color paint (i.e., natural colors such as green or brown) and appropriate surface material finishing (see section 4.7.2.7). This alternative would have the lowest cost, the highest engineering/design feasibility and, aside from visual impacts, the smallest environment impact of the three alternatives. Therefore, at-grade LNG storage tanks were selected for use on the proposed project.

Below-grade LNG storage tanks would use the same design as the at-grade tanks but would be placed in excavated pits to reduce the height of the tank located above the ground surface. The pits would be designed to mitigate potential earthquakes and flooding, impacts resulting from the excavation, and dewatering during excavation. Depending on the final depth of the tanks, 0.5 to 1.0 million cubic yards of

soil would be excavated and taken off site. The 40,000 to 80,000 truck trips necessary to transport this soil would have associated traffic, noise, and air quality impacts. The dewatering that would be required during excavation, and permanent groundwater control requirements, could have impacts on groundwater and surface water resources. Use of below-grade LNG storage tanks would extend the project schedule by up to 1 year compared to at-grade storage tanks, and it is the most expensive LNG storage tank alternative. Below-grade LNG tanks have not been used or proposed for any LNG import project in North America.

A type of low-profile LNG storage tank, referred to as LNG Smart Horizontal Tank Storage, has been developed by Mustang Engineering but has not been used on a scale as large as the proposed project. These tanks would consist of multiple horizontal vessels located inside a concrete box. Many smaller horizontal vessels would be required to provide the storage capacity required by the project, resulting in a 65 percent increase in the size of the LNG storage tank area. This increased area would have a corresponding increase on environmental impacts at the terminal site and could make future expansion of the terminal difficult or impossible. Although not as costly as the below-grade tank alternative, this alternative would be significantly more expensive than the conventional above-grade LNG storage tanks.

3.1.6.2 Alternative LNG Terminal Layout

As proposed, the Bradwood Landing LNG terminal would require the permanent development of 40 acres. This is a relatively small footprint compared to many existing LNG import terminals in the United States, which may occupy as much as 318 acres (i.e., Cove Point). In originally developing the LNG terminal layout at Bradwood, NorthernStar considered engineering/design, worker safety, economic, and environmental factors.

Through consultation with various resource agencies, NorthernStar has continued to refine the facility layout to minimize environmental effects. Specifically, NorthernStar considered alternative LNG terminal site configurations to reduce impacts on wetlands. The original site boundary was modified by truncating the northwest and southwest corners. This modification reduced the area of wetlands that would be filled with dredged material by 3.1 acres (16 acres covered by the original layout as compared to 12.9 acres by the modified layout). NorthernStar indicated that no additional reductions in wetland impacts, including retaining the log pond, are possible because remaining areas of the terminal site are needed for LNG terminal facilities, operations, utilities, a maintenance area, safety buffers, circulation, stormwater management, an emergency helicopter landing area, and laydown areas for construction. For example, the area used for stormwater management must have adequate capacity to temporarily retain water after a large storm event prior to infiltration. During annual critical maintenance events known as “turn overs,” the maintenance area would be fully occupied by a full range of construction equipment (including cranes, trucks, welding machines and other large pieces), contractor trailers, and facility parts. Furthermore, the helicopter landing area must be located a safe distance from equipment filled with flammable liquids. Additional reductions in the site size and/or other alternative site layouts would reduce efficient use of space and could risk worker safety during construction or operation of the facility.

As described in section 2.9, NorthernStar has not committed to expanding the proposed LNG terminal. However, if there is a future demand for additional natural gas in the market area, provisions have been made in the layout of the site to allow for a possible future expansion by adding a third LNG storage tank and other equipment/facilities. Failing to plan for a growth in market demand and subsequent expansion of the LNG terminal to serve this demand may severely compromise the ability of NorthernStar to expand in the future. If the facility is not designed to accommodate reasonable changes, future expansion activities could be unnecessarily expensive, require schedule delays for subsequent permitting, and/or involve additional environmental impacts. According to NorthernStar, designing a

project to allow for future expansion is a typical model for energy projects of this size and is necessary to make the project viable.

3.1.6.3 Alternative Vaporization Technologies

There are various designs of equipment that are used to warm LNG to the point it returns to a gaseous state. NorthernStar considered engineering feasibility, operational requirements, reliability, safety, past commercial application, environmental impacts, and permitting feasibility as the main criteria in selecting the vaporization equipment for the Bradwood Landing Project. The basic technologies assessed by NorthernStar were ORVs, SCVs, STVs, and water baths.

Various sources of heat were considered, including ambient air, river water, natural gas, electric power, wood chips, and waste heat from cogeneration. Ambient air-heated vaporizers were initially considered for the Bradwood Landing Project but were determined to be infeasible because of the long periods of cool, wet weather typical for this area. Technologies relying on electric power for heating were also eliminated because the amount of power necessary could not be generated on site and could not be purchased for an acceptable price. Burning of wood chips for a heating source was eliminated because of the large variability in wood chip costs over time, air emissions, lack of storage areas on site for the wood chips, and because of potential impacts associated with transporting large volumes of wood chips to the site.

Waste heat from cogeneration was eliminated as a source for vaporization because of substantial uncertainties regarding the transmission of power out of the facility. Specifically, in order to implement this alternative, there was a possibility NorthernStar might have to construct a 50-mile-long power line out of the facility to a connection with the existing BPA grid. To remove the uncertainty associated with the power line, NorthernStar would need to pay now for capacity in the grid that it would not need for some time in the future in order to use the grid. Constructing this transmission line and purchasing this capacity would be prohibitively expensive.

Based on its analysis of the various technologies and heat sources, NorthernStar chose SCV with natural gas for vaporization at the Bradwood Landing LNG terminal. Because NorthernStar selected a vaporizer design that utilizes the combustion of natural gas for heating, and air emissions would be generated, other designs were evaluated to determine if an alternative design could result in reduced impacts. For purposes of an environmental comparison, vaporizers can be broadly categorized into two groups depending on whether or not they require on-site combustion of a fuel to warm the LNG.

Natural Gas Combustion

Three vaporizers that use natural gas combustion were considered for the Bradwood Landing Project, the SCV, water bath, and STV.

SCVs are generally based around a concrete structure containing a water bath with submerged stainless steel pipe coils. LNG enters the coils and, as it is warmed by the water bath, the vaporized LNG (natural gas) exits the coils. The water bath is warmed by burning natural gas. Blowers provide combustion air at a pressure sufficient to force the combustion emissions up through the water bath where they heat the water. SCVs typically consume about 1.5 percent of the sendout natural gas from the terminal. This type of vaporization system is very efficient and is able to accommodate wide fluctuations in the amount of LNG vaporized. SCVs tend to have higher air emissions, particularly NO_x, than other combustion units because the use of selective catalytic methods to control emissions has not proven reliable. Excess condensate water, on the order of several million gallons per day (mgd), is produced.

Disposal of the excess water requires treatment with alkaline chemicals to neutralize the acidity caused by absorbed CO₂.

Water baths use an open bath containing combustion tubes and LNG tubes. The fired gases transfer heat through the combustion tubes to the water bath and the water bath transfers heat to the LNG piping. The combustion gases and the water bath are not in direct contact with each other (unlike in SCVs). The combustion gases are discharged to the atmosphere. Approximately 2 percent of the natural gas produced by the terminal would be used in this process resulting in more air emissions than SCVs. This system is less efficient than SCVs.

STV systems involve a heat exchanger in which tubes containing LNG pass through a shell containing a counter-current of heat exchange media such as a water/glycol mixture. On the opposite end of the heat exchanger loop, the water/glycol mixture is typically heated by using direct-fired combustors burning natural gas. However, the source of heat may vary depending on the particular design. For this project, a vertical shell and tube design with a closed-loop hot water system that provides heat to the vaporizers was considered. The water is heated using direct-fired heaters that run on natural gas. About 100,000 gallons of fresh water would be necessary to operate this closed-loop system. An advantage of the STV is that selective catalytic reduction systems and oxidation catalysts can be used on the heaters to reduce NO_x and CO emissions.

Estimated air emissions with the currently proposed SCVs, as well as water baths and STVs, are presented in table 3.1.6-1.

TABLE 3.1.6-1			
Estimated Air Emissions Associated with Vaporizer Combustion			
Vaporizer Design	Air Emissions (tpy) ^a		
	NO _x	CO ^b	PM ₁₀
SCV ^c	121.9	199.3	13.4
Water Bath ^d	310	261	24
STV ^d	310	261	24
^a Based on a sendout rate of 1.0 Bcfd and 12-month operation of vaporizers. ^b Carbon monoxide. ^c Currently proposed design. The SCV firing rate is estimated at 17 MMcfd, based upon a 120 MMBTU/hr heat rate. ^d Based on large wall-fired boiler with flue gas recirculation and low NO _x burners, assuming 17 MMcfd firing rate. Estimated from EPA AP-42 guidelines for external combustion engines – boilers.			

As indicated in the table, SCVs have lower emissions than STVs or water baths with limited controls. It should be noted, however, that if oxidation catalysts were to be used on any of the resulting gas streams, a reduction of 90 percent could be realized in CO and VOCs. If STVs were to be used, selective catalyst reduction could be used to significantly reduce NO_x emissions.

None of these vaporizer technologies would use water from the Columbia River. The water bath and STV would not discharge water to the river, but SCV would generate water condensate that would be discharged to the Columbia River at a rate of 160 gpm and a temperature of about 68 °F. This discharge water would contain approximately 0.4 percent of sodium carbonate and trace amounts of sodium nitrate and other sodium salts, but would not require treatment other than pH neutralization.

Non-Combustion Alternatives

At some locations with warm climates, it is possible to use ambient warm air or ambient warm water as a source of the heat needed to vaporize the LNG. The advantage of vaporizers that utilize ambient air or water vaporization systems is that air emissions tend to be lower than for a system that involves combustion of a hydrocarbon fuel (Coast Guard and MARAD, 2003). Although air or water vaporizers can result in very small quantities of air emissions associated with electrical generation required to power fans or pumps, the power is generally produced off-site and the amount needed for the vaporizers is relatively minor (Coast Guard and MARAD, 2003).

Ambient air-heated vaporizers use air warming structures to warm and vaporize the LNG. Because the surface area of the heat exchangers needs to be large for efficient heat transfer, the structures would be large and require significant space for construction and operation. Ambient air-heated vaporizers utilize air warming structures as heat exchangers to recirculate the cooled water from the water bath and warm it through exposure to the air. Because the surface area of the water–air interface needs to be large for efficient heat transfer, the structures are generally large and require significant space for construction and operation. Because water would condense on the warming structures, ambient air vaporizers at the Bradwood Landing LNG terminal would produce about 1.3 mgd of water during operation compared to approximately 0.4 mgd for operation of SCV units. Ambient air-heated vaporizers were not considered practical for the Bradwood Landing Project because of limitations associated with periods of cool weather along the Columbia River.

River water, used exclusively as a heat source for vaporization, was also eliminated as a practical vaporization technology for the Bradwood Landing Project. However, river water was considered further in combination with the use of either natural gas fired SCVs or STVs during the coolest 5 months of the year. If the river water temperature is above approximately 63 °F, the water can typically serve as the sole heat source for LNG vaporization. When water temperatures drop to between 50 °F and 63 °F, supplemental heat is typically required. As an indication of river water temperatures in the vicinity of the proposed site, in 1996, the mean temperatures measured 3 miles upstream from the proposed LNG terminal site ranged from a low of 41 °F in March to a high of 71.4 °F in July (U.S. Geological Survey (USGS), 1996).

For the Bradwood Landing Project, a water-based vaporization system would require withdrawing (and discharging) large volumes of water from the Columbia River. The water would be treated for sodium hypochlorite with sodium bisulphite before discharging at a rate of 100,000 gpm. On other LNG terminal projects (e.g., Long Beach LNG Import Project), agencies such as the NMFS have expressed concerns that significant numbers of fish and/or fish larvae could be entrained during the withdrawal of water. With the large number of federally protected species found in the Columbia River (see section 4.6.1.1), concerns related to entrainment are particularly relevant. Additional concerns have been raised about the thermal plume associated with discharging cold water back into the affected waterbody. NorthernStar estimates there would be a maximum decrease of 14 °F in the discharge water compared to the ambient river water temperature. Although the use of river water during 7 months of the year would result in decreased air emissions compared to technologies that use combustion year round, given the environmental concerns associated with withdrawal and discharge of the river water, this vaporization technology would not offer an overall environmental advantage compared to SCVs.

3.1.6.4 Alternative Fill Sources

Geotechnically suitable fill is required to raise the grade at the LNG terminal site to 20 feet NAVD. NorthernStar proposes to use up to about 700,000 cubic yards of material dredged from the maneuvering area in the Columbia River for this purpose. Additional dredged material may be placed at

the terminal site but would not be necessary for design purposes. During preliminary meetings held to discuss the content of the BA, the agencies requested an analysis be performed for an alternative source or sources of fill that would be from an upland area so that material dredged for the ship berth and maneuvering area could be used for in-river placement. NorthernStar determined that the most likely upland fill source would be Teavin's Pit, a permitted aggregate mine. The cost of the fill would be between \$3.5 million and \$5.2 million. Transporting about 400,000 cubic yards of fill to the proposed LNG terminal site would require about 10,500 truck loads at an estimated round-trip travel time of 30 minutes, totaling 5,250 hours of truck time. In addition, four pieces of heavy equipment would be required, totaling about 21,000 hours. The pollution generated from operation of the truck and heavy equipment would result in the following emissions:

- 53.5 tons of carbon monoxide (CO);
- 43.5 tons of NO_x;
- 6.3 tons of SO_x;
- 2.5 tons of particulates (does not include dust generated from the fill handling itself); and
- 1.3 tons of volatile organic compounds (VOC).

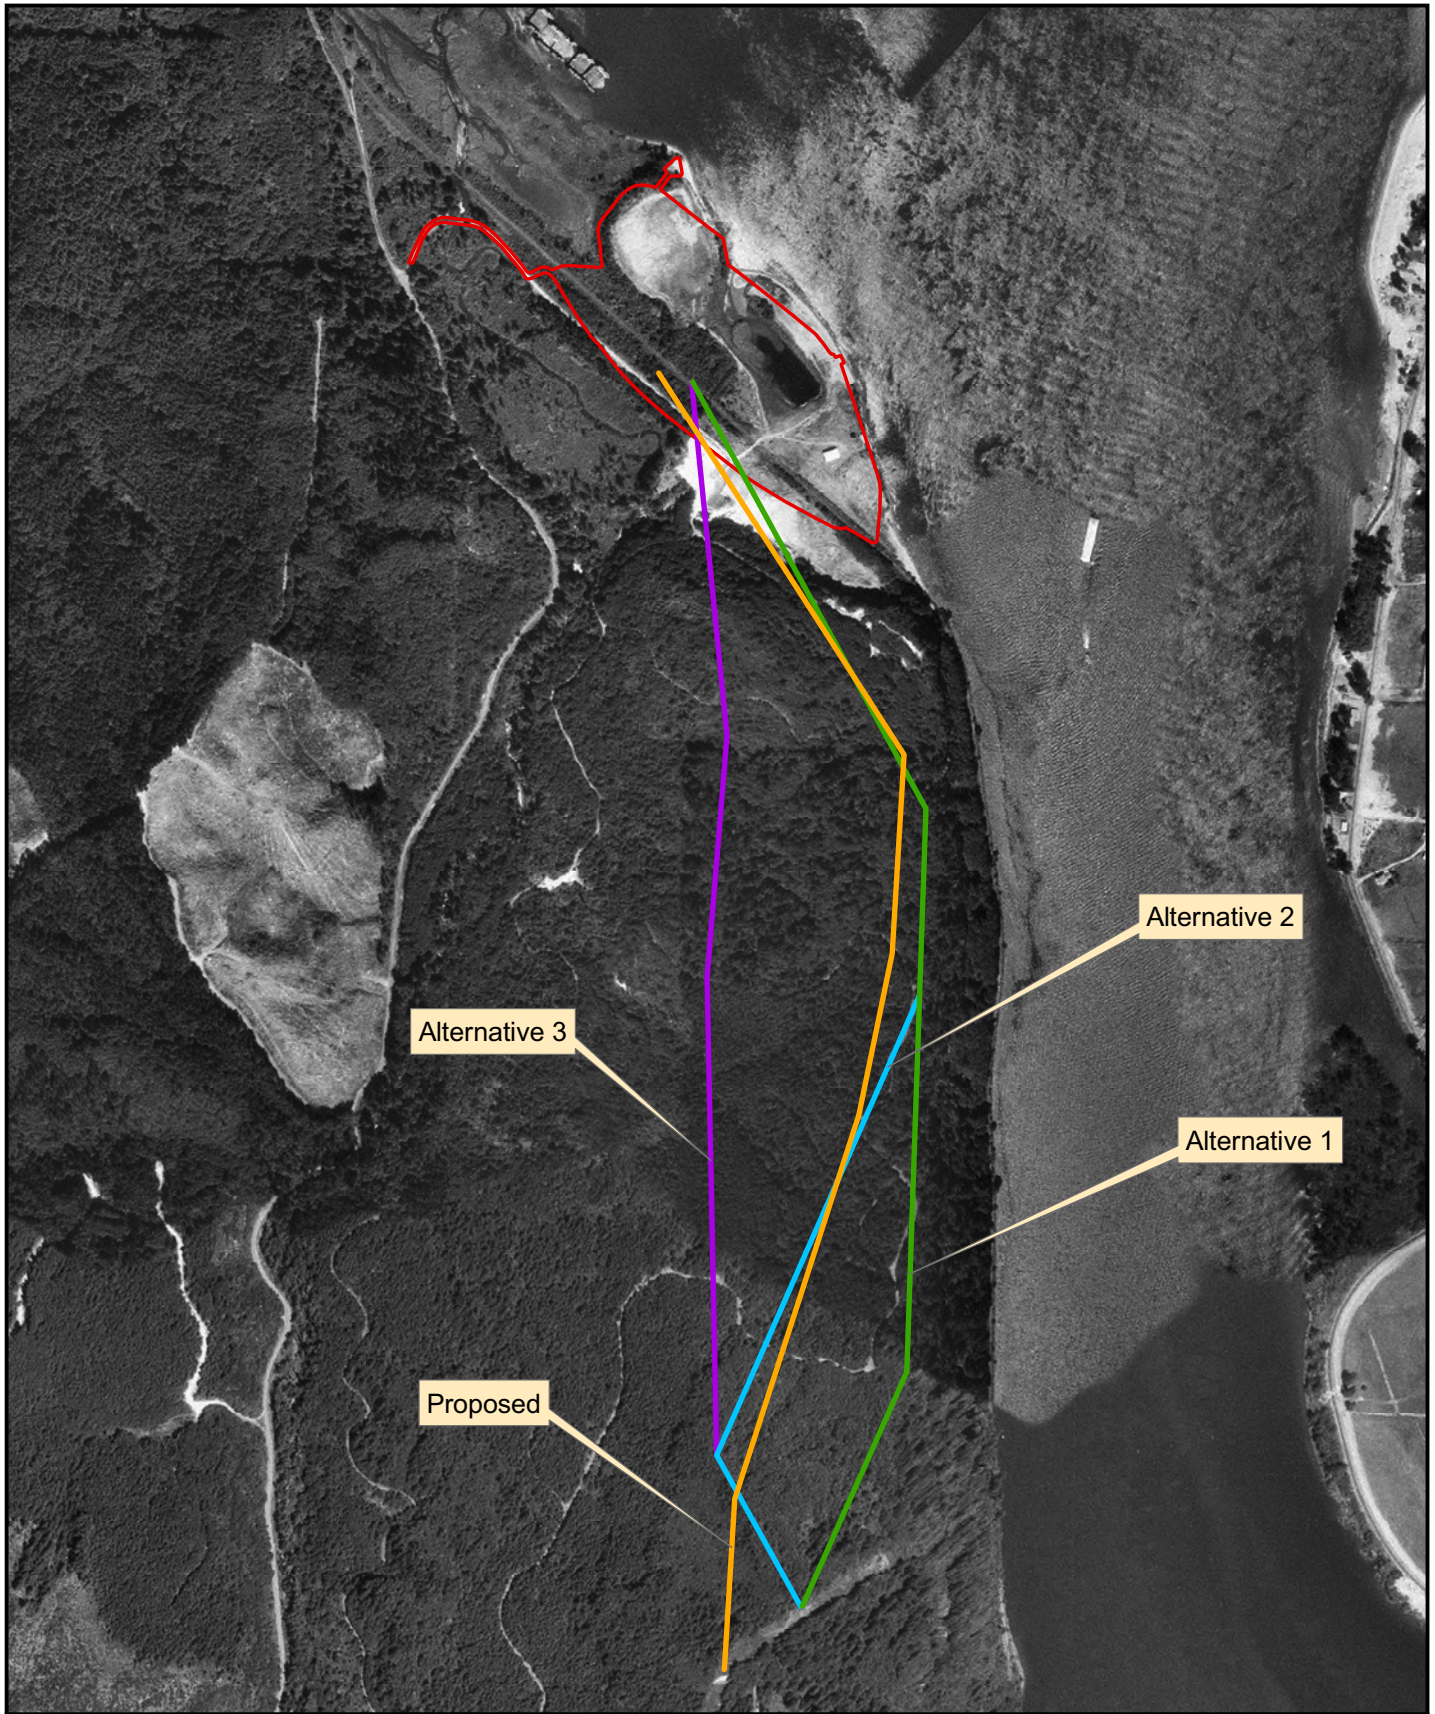

In addition, increased emissions would result from the increased time that the dredge would operate in order to transport the dredged material a greater distance to an alternative placement site. Given the increased air emissions and economic costs of trucking in fill material to raise the LNG terminal site, this alternative does not appear to offer a significant environmental advantage over the proposed source of fill.

3.1.7 Power Line Route Alternatives

As described in section 2.2.1, a 1.5-mile-long non-jurisdictional electric power line would be constructed on a 105-foot-wide right-of-way to bring electricity to the terminal. Five new 69-foot-high H-frame structures would be constructed for the power line and an existing BPA tower would be rebuilt. NorthernStar evaluated four alternative power line routes from the BPA system to the terminal: Alternative Route 1, located closest to the Columbia River; Alternative Route 2, located west of Alternative Route 1; Alternative Route 3, located west of Alternative Route 2, and the proposed route, located between Alternative Route 1 and Alternative Route 2. These routes are depicted on figure 3.1.7-1.

The alternative routes are generally similar with respect to overall length, habitats crossed, and most other important characteristics. Alternative Route 3 is slightly shorter than the other two routes. Use of Alternative Routes 2 and 3 would result in clearing of more closed canopy forest than Alternative Route 1. NorthernStar initially selected Alternative Route 1 for the power line on the basis that this route would result in less visual impacts on sensitive viewers on Puget Island because it is located at a lower elevation, and the hillside on which much of the route is located would be present as background when viewed from Puget Island. However, Alternative Route 1 crosses late-successional (old growth) conifer forest. The proposed power line route completely avoids the old growth forest. In some places the power line would be visible against the sky when viewed from Puget Island, but the overall visual impact would be minor.

The proposed power line route is 0.1 mile shorter than Alternative Route 1 and crosses better topography for construction. Existing access roads could be used for both Alternative Route 1 and the proposed route but the proposed route would require approximately 465 feet of additional access roads for construction and maintenance of the H-pole towers. No wetlands would be affected by construction of the additional access roads.

 — Alternative 3 Landing LNG Terminal

0 600 1,200 1,800 2,400
Feet

Figure 3.1.7-1
Bradwood Landing Project
Power Line Route Alternatives

NorthernStar also evaluated the feasibility of a power line route following Clifton Road. The absence of a right-of-way along Clifton Road and steep topography would make construction of the H-towers difficult and the route would be about 2 miles longer than the proposed route. The Clifton Road route would cross Hunt Creek twice. Such a route would have no advantages over the proposed route and the waterbody crossings would result in impacts on riparian and estuarine habitats.

3.1.8 Pipeline Route Alternatives

We assessed whether it might be possible to reduce the environmental impacts associated with construction and operation of the proposed sendout pipeline by following a major route alternative. Additionally, we evaluated minor variations to the proposed pipeline route to avoid or minimize impacts on specific, localized resources such as residences, waterbodies, forest habitat, and wetlands.

3.1.8.1 Major Pipeline Route Alternatives

Alternatives to the proposed pipeline route would have to meet the project objective of transporting natural gas from the Bradwood Landing LNG terminal to existing and future markets in the Pacific Northwest. Specifically, the project is designed to provide up to 1.3 Bcfd of natural gas to the region by: 1) delivering natural gas to the Georgia-Pacific paper mill at Wauna, Oregon and the PGE Beaver Power Plant at Port Westward, Oregon; 2) interconnecting with Northwest Natural's existing bidirectional intrastate pipeline facilities capable of transporting gas to their Mist underground storage facility; and 3) interconnecting with the Williams Northwest interstate pipeline system.

NorthernStar considered three major alternatives to the proposed sendout pipeline route: 1) the Railroad Route Alternative, 2) the Northern Route Alternative, and 3) the Southern Route Alternative (see figure 3.1.8-1). In addition, a route alternative requiring crossing of the Columbia River at Bradwood Landing was initially considered. However, due to the limitations of HDD technology and the length of the crossing at this location, the route was determined to be unconstructable and was eliminated from further consideration.

Railroad Route Alternative

The Railroad Route Alternative would parallel the existing PWRR from Bradwood Landing to Rainier, Oregon. The pipeline would then cross the Columbia River by HDD methods and terminate at Williams Northwest pipeline, southeast of Longview, Washington. The total approximate length of this alternative is 35.8 miles, which would be slightly shorter than the proposed route. NorthernStar evaluated this alternative in an effort to minimize project impacts on environmental resources by collocating the project within an existing industrial corridor.

Although this route alternative achieves delivery to interstate markets, it fails to meet the project objective of delivery to the PGE Beaver Power Plant at Port Westward without the construction of a lateral that would significantly increase the overall length of the pipeline system and subsequently increase the number of landowners and environmental resources impacted by the project. Additionally, the portion of the railroad bed between Bradwood Landing and the Georgia Pacific paper mill at Wauna, Oregon is adjacent to a basalt ledge that would require blasting for installation of the pipeline. Blasting could result in stability issues for the railroad bed.

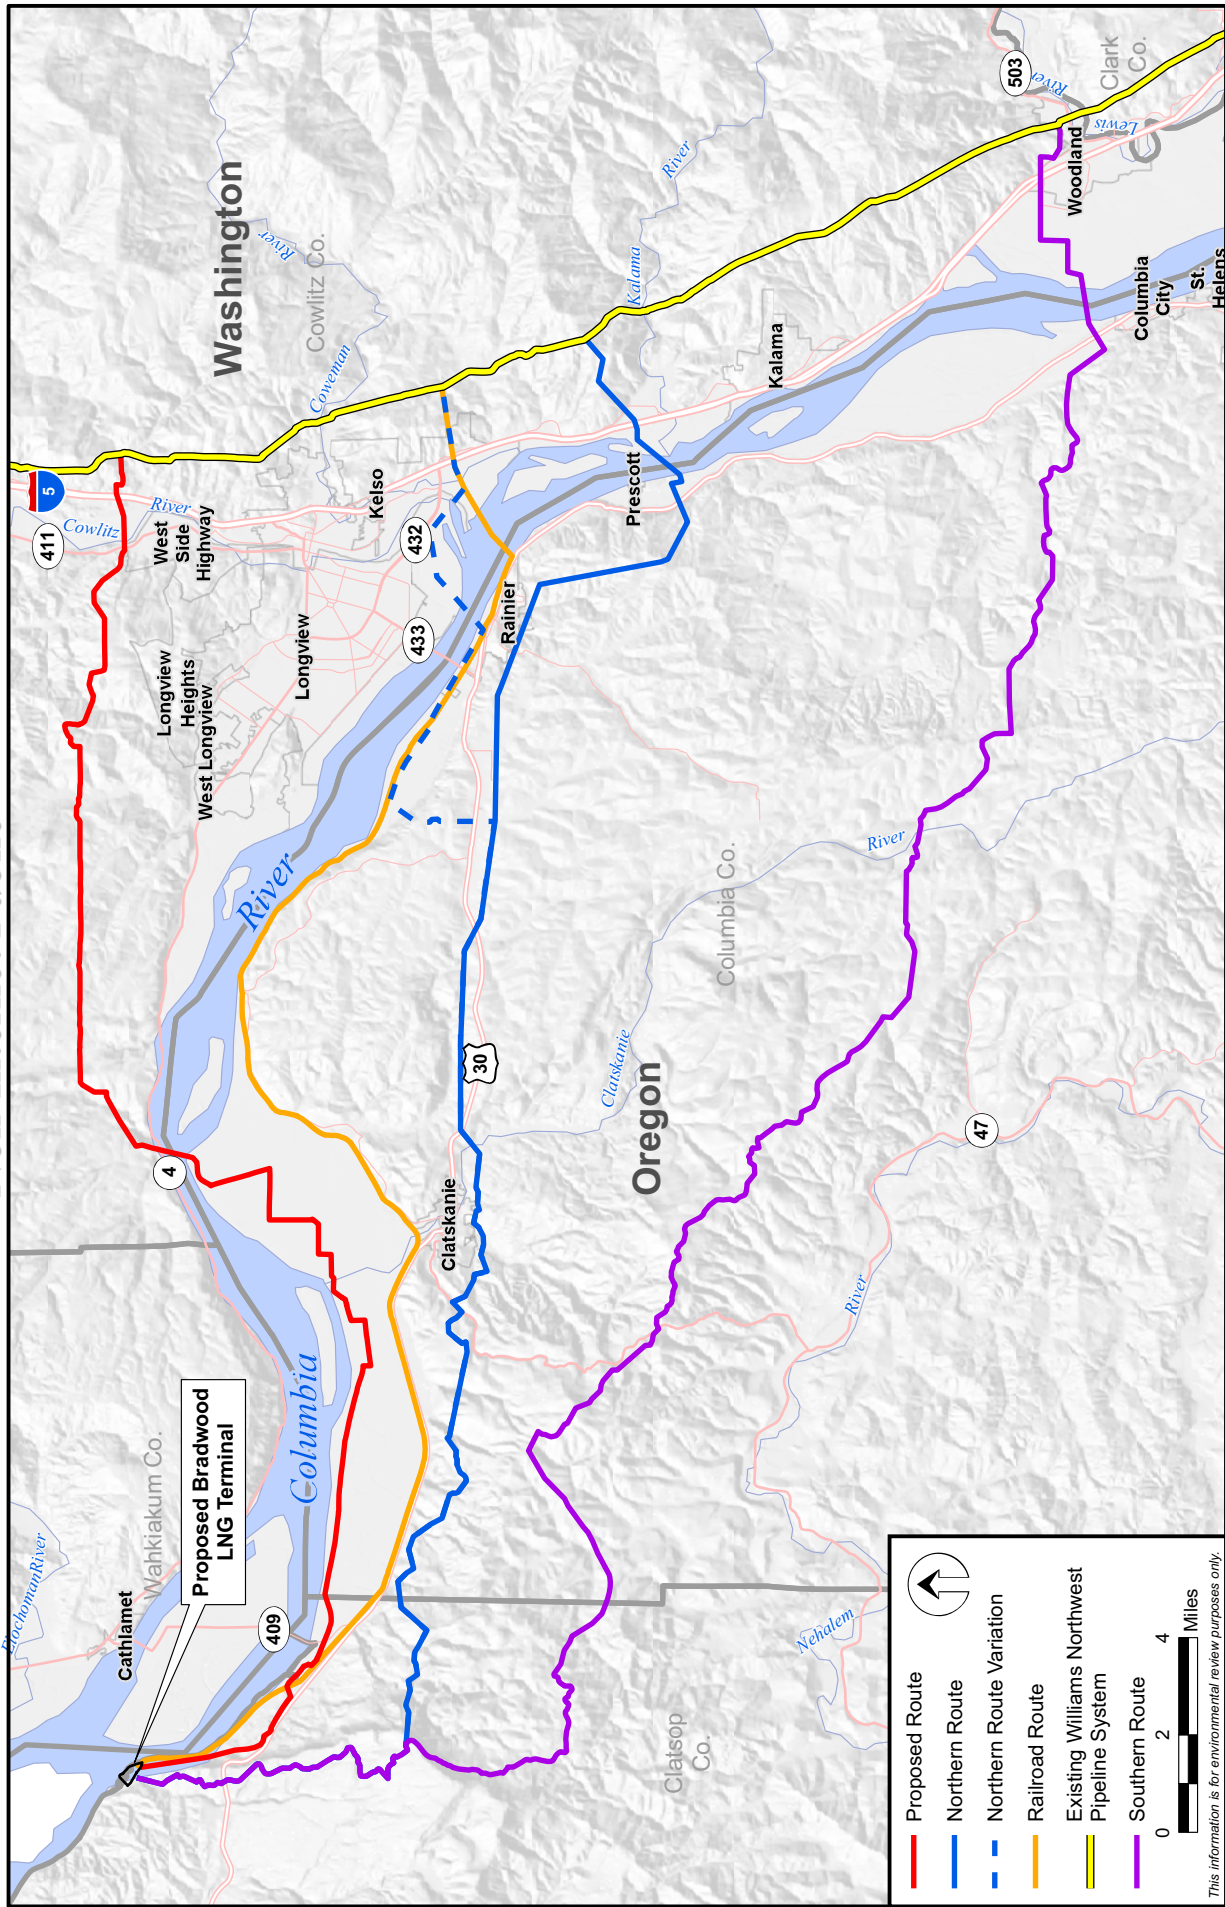

Figure 3.1.8-1
Bradwood Landing Project
 Major Pipeline Route Alternatives

Northern Route Alternative

The Northern Route Alternative would exit the LNG terminal site to the south and continue along Nikolai Ridge for approximately 6 miles. The pipeline would then turn to the east and parallel, where possible, existing logging roads and other rights-of-way, proceeding south of Clatskanie, and turning roughly southeast at Rainier, to the vicinity of Prescott, Oregon. The pipeline would cross the Columbia River using the HDD construction method near the decommissioned Trojan nuclear power plant, and continue east to tie-in with the Williams Northwest pipeline system north of Kalama, Washington. The approximate length of this alternative route is 42.6 miles. This was the route originally proposed by NorthernStar when it entered into the FERC's Pre-filing Process in March 2005.

Although this route alternative would achieve delivery to interstate markets, it fails to meet the project objective of delivery to the PGE Beaver Power Plant at Port Westward without the construction of a lateral, which would significantly increase the overall length of the pipeline system and subsequently increase the numbers of landowners and environmental resources impacted by the project. Additionally, crossing under the Columbia River near the decommissioned Trojan nuclear power plant using the HDD method would be problematic due to the width of the river at this location. The Port of Kalama raised objections about this route because of potential impacts the crossing of the Columbia River may have on future port development activities.

A variation of the Northern Route, referred to as the Longview Alternative, was also considered. The Longview Alternative would follow the Northern Route to near Rainier, cross the Columbia River into Longview, Washington, then proceed east to tie-in with the Williams Northwest pipeline system. The Longview Alternative would decrease the length of the Northern Route by 1.3 miles and avoid impacting the Port of Kalama property. However, this variation would still be 5.0 miles longer than the proposed route and the crossing of the Columbia River would be difficult at the Longview Alternative location.

Southern Route Alternative

The Southern Route Alternative would exit the LNG terminal site to the south and continue along Nikolai Ridge for approximately 9 miles. The pipeline would then follow a mostly southeast alignment to a point south of Deer Island, Oregon, cross the Columbia River by HDD methods, and terminate at a tie-in with the Williams Northwest pipeline system north of Woodland, Washington. The length of this alternative is about 55.0 miles, which would be 18.7 miles longer than the proposed route.

Although this route alternative achieves delivery to interstate markets, it fails to meet the project objective of delivery to the PGE Beaver Power Plant at Port Westward without the construction of a lateral which would significantly increase the overall length of the pipeline system and subsequently increase the numbers of landowners and environmental resources impacted by the project. Because of the large increase in length compared to the proposed route, the overall footprint of the project (including extra workspaces and access roads) would significantly increase the potential for environmental impacts compared to the proposed pipeline route.

Major Pipeline Route Alternatives Conclusion

Table 3.1.8-1 compares the proposed Bradwood Landing pipeline route to the three alternative routes. As indicated by table 3.1.8-1, the Railroad Route Alternative would be the shortest route and the Southern Route Alternative would be the longest. The proposed route, which would be only slightly longer than the Railroad Route Alternative, would have the fewest residences within 50 feet of the construction right-of-way; the Railroad Route Alternative would have the most nearby residences. The Railroad Route Alternative would also have the most commercial and industrial structures within 50 feet of the construction right-of-way. The proposed route would cross the most waterbodies; however, a relatively large number of manmade ditches (approximately 36) within agricultural land between Westport and Port Westward account for a majority of the additional waterbodies along the proposed route. The Railroad and the Southern Routes would cross the fewest waterbodies, but the Railroad Route Alternative would cross the most wetlands. Although the proposed route would cross significantly more agricultural land than three of the other alternative routes, the impacts on agricultural lands would generally be temporary (i.e., these lands would return to agricultural production within one growing season). With the exception of the Railroad Route Alternative, the proposed route would impact the least amount of forested land.

The proposed route presents advantages over the three alternative routes in terms of environmental impacts, constructability (i.e., blasting in proximity to a railroad bed), proximity to populations, and proximity to target markets. Because this route is shorter than the Southern Route and Northern Route, and the Railroad Route would require a lateral to meet the object of supplying natural gas to the Beaver Power Plant, the overall area that would be impacted would be less. Therefore, we agree that the proposed route is preferred over the alternative routes.

3.1.8.2 Minor Pipeline Route Variations

During refinement of the proposed Bradwood Landing pipeline route, a number of minor route variations were considered by NorthernStar in an effort to eliminate or minimize potential impacts on specific localized resources, including residences, wetlands, or waterbodies. Route variations were also identified as specific landowner concerns were raised. In some cases, NorthernStar determined that the new route variation would be preferable to the initially proposed route segment and in other cases, the initial route segment was determined to be the best option. We reviewed the route variations identified by NorthernStar and agree that the selected route segments (whether initial route segment or an alternative route variation) would reduce the overall environmental impacts of the project. These route variations are summarized in table 3.1.8-2, and depicted on the proposed route maps in Appendix B. Additional route variations might be proposed in conjunction with completion of the Final Pipeline Design Geotechnical Report to minimize slope stability problems along the route.

3.1.9 Dredging and Dredged Material Placement Alternatives

As discussed in section 2.4.1.2, NorthernStar would dredge up to about 700,000 cubic yards of sediment from the ship berth and maneuvering area to enable LNG carriers to dock and turn in the Columbia River. This volume was determined based on the minimum amount needed to safely accommodate LNG carriers. Alternatives requiring more dredging could be identified; however, alternatives requiring less dredging would not be able to safely accommodate LNG carriers. As such, we did not consider it feasible to reduce the volume or extent of dredging and still satisfy the objectives of the project at the proposed site.

TABLE 3.1.8-1

Comparison of the Proposed Bradwood Landing Pipeline to the Alternative Routes

Environmental Factor	Proposed	Railroad	Northern	Northern with Longview Alternative	Southern
Total length (miles)	36.3	35.8	42.6	41.3	55.0
Permanent Right-of-Way (acres) ^a	220.0	216.0	258.2	250.3	333.3
Extra Work Spaces (number)	61	109	86	89	124
Residences within 50 feet of Construction Right-of-Way (number)	13	32	28	20	15
Commercial or Industrial Structures within 50 feet of Construction Right-of-Way (number)	13	19	1	5	0
Perennial Waterbodies Crossed (number) ^b	61	26	43	44	28
Wetlands Crossed (miles) ^c					
<i>Palustrine Forested</i>	0.2	1.4	0.2	0.8	0.6
<i>Palustrine Nonforested</i>	5.8	3.7	0.9	1.7	0.5
<i>Palustrine Combination Forested/Nonforested</i>	0	0.9	<0.1	0.0	0.0

<i>Total</i>	6.9	7.8	1.7	2.9	1.7
Federal and/or State Threatened and Endangered Species					
<i>Fish species inhabiting waterbodies crossed (number)</i>	10	9	9	10	9
<i>Waterbody crossings through habitats of one or more fish species (number)</i>	13	14	11	11	12
<i>Bird species within 0.5 mile of route (number)</i>	2	4	3	4	5
<i>Bird nest locations within 0.5 mile of route (number)</i>	7	4	4	4	3
<i>Priority bird habitats, species, and nest buffers within 0.5 mile of route (number)</i>	9	7	9	7	7
<i>Bird habitat to be disturbed (acres) ^d</i>	4.9	18.2	61.4	68.9	66.7
<i>Amphibian species/habitats within 0.25 mile of route (number)</i>	1	0	0	0	0
<i>Reptile species/habitats within 0.25 mile of route (number)</i>	0	0	0	0	0
<i>Plant species/habitats within 0.25 mile of route (number)</i>	2	1	4	3	3
<i>Plant species habitat to be disturbed (acres) ^d</i>	68.9	63.7	2.5	68.6	57.8
<i>Mammals species/habitats within 0.25 mile of route (number)</i>	4	3	2	2	1
<i>Mammal species habitat to be disturbed (acres) ^{d,e}</i>	99.8	82.1	29.8	29.8	25.1
Public Lands Crossed (miles)	0.2	0.0	6.7	4.9	12.1
Agricultural Land Affected (acres) ^d	166.1	163.2	22.5	48.1	52.1
Forest Required to be Cleared (acres) ^d	228.9	163.1	462.9	378.8	587.0
Roads Crossed (number)	49	103	82	81	121
Major Utilities Crossed (number)	5	4	9	7	5

^a Assumes a 50-foot-wide permanent right-of-way throughout.

^b Includes manmade ditches.

^c Based on NWI data for all routes, including the proposed route.

^d Assumes a 100-foot-wide construction right-of-way throughout.

^e Based on GIS calculation of the sum of habitats from the WDFW, Priority Habitats and Species and Oregon Natural Heritage Information Center databases.

TABLE 3.1.8-2

Minor Route Variations Evaluated for the Proposed Pipeline Route by NorthernStar

Variation	Beginning MP	Reason Route Variations Were Evaluated and Selected	Initial Route Segment Length (miles)	Alternative Route Variation Length (miles)
NS-1	0.0	Impacts on environmental resources, including forest habitat, waterbodies, and wetlands, would be avoided along Nikolai Ridge by using the HDD method along the initial route segment as opposed to trenching along the alternative route variation. Also, the initial route segment would be 0.19 mile shorter.	1.6 selected	1.7
NS-2	2.6	The initial route segment is slightly longer; however, alignment along a secondary road within Georgia-Pacific property and within scrub-shrub habitat (an area that appears to have been clear-cut and is dominated by non-native Himalayan blackberry) avoids impacts on forest habitat.	0.2 selected	0.2
NS-3	10.7	The selected alternative route variation follows property boundaries and would minimize impacts on agricultural fields in response to landowner concerns. Additionally, the selected route would be further from residences than the initial route segment. Slightly more emergent wetlands would be temporarily impacted along the selected alternative route variation compared to the initial route segment.	1.7	2.2 selected
NS-4	13.5	The alternative route variation was selected in response to landowner concerns. Although longer than the initial route segment, the alternative follows property boundaries and road alignments and would minimize impacts on active agricultural areas without significant additional construction impacts on natural resources.	3.1	4.7 selected
NS-5	19.0	The initial route segment was considered so existing roads could be used to avoid impacts on forested areas. The alternative route was selected because it would minimize impacts on landowners associated with the use of private roads. Impacts on natural resources are generally consistent between the two segments.	1.3	1.2 selected
NS-6	20.3	The initial route segment was selected over the alternative route variation because it would minimize impacts on property owners. Other impacts are generally consistent between the two route segments.	1.4 selected	1.6
NS-7	31.1	The alternative route variation was selected to accommodate landowner concerns related to a pond/spring on their property. The alternative route follows a ridgeline on the property to increase the distance between the pipeline and the pond/spring - the nearest portion of the proposed construction work area is 450 feet west and 1,150 feet south of the pond/spring.	0.3	0.3 selected
NS-8	33.9	This alternative route variation considered a different location for the entry pit of the HDD borehole that would cross the Cowlitz River, taking into consideration the proximity of residences, oak trees, and the scales of a rock pit. The HDD entry pit work space for the alternative route variation would be within 300 feet from several residences compared to more than 600 feet for that of the initially proposed route; however, the initially proposed work space would be 50 feet from a residence and would damage oak trees and the rock pit scales. Also, the selected alternative route variation would use an abandoned power line right-of-way.	1.1	1.1 selected
NS-9	35.1	Although 1.25 acres more forest habitat would be impacted, the initial route segment would avoid several residences east of Interstate Highway 5 compared to the alternative route variation.	1.2 selected	1.1

Note: Comparisons of wetland impacts were made using NWI data for consistency rather than actual field delineations.

Dredging and dredging related activities would be conducted in accordance with applicable federal, state, and local permit stipulations. To avoid or minimize impacts on water quality or biological resources associated with these activities, alternative dredging methods and dredge disposal alternatives were considered.

Dredging and placement of structures within waters of the United States requires authorization from the COE under section 404 of the CWA and section 10 of the RHA (see section 1.3). As an element of its review, the COE is required to consider whether a proposed project represents the least environmentally damaging practicable alternative pursuant to the CWA section 404(b)(1) guidelines (40 CFR 230). The term practicable means available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes. As a cooperating agency, the COE has recommended that the alternatives analysis in this EIS consider project design, configuration, and construction alternatives that avoid or minimize effects on the aquatic environment. In this way, this EIS could be used to identify the COE's least environmentally damaging practicable alternative.

Ultimately, activities associated with dredging, as well as construction of the LNG carrier berth and unloading facility, would be conducted in accordance with COE permit stipulations as well as the requirements of state and local permits (see section 1.3). To avoid or minimize impacts on water quality or biological resources associated with these activities (see sections 4.3.2.2 and 4.5.2.1), alternative dredging methods and dredged material placement areas were considered.

3.1.9.1 Alternative Dredging Methods

Dredging technologies can be separated into two basic categories, hydraulic and mechanical. Two types of hydraulic dredge units (self-propelled hopper dredges and cutterhead pipeline dredges) have historically been used in the Columbia River area. The hopper dredge is a seagoing vessel that can move from one area to another under its own power. It excavates dredged material by lowering drag arms onto the bottom to dislodge material, and then suctions the material into the hopper, or holding area. In order to effectively operate, a hopper dredge must be moving forward while dredging, and it typically operates most efficiently over long distances, such as in navigation channels. A hopper dredge would not be well suited for this project because of the relatively confined work space at the proposed LNG terminal.

A hydraulic cutterhead pipeline dredge uses its cutterhead to break up the materials to be dredged, then suctions the material into a pipeline. Prior to dredging, the pipeline is laid between the site to be dredged and the dredged material placement area. The pumping distance is a limiting factor for selection of this method. The typical maximum pumping distance is roughly 2 miles but use of booster pumps can increase the distance to 5 to 8 miles, depending on the grain size of the sediment. Dredging production rates are dependent on the characteristics of the materials to be dredged, the equipment employed in the operation, and the length of the pipeline. Hydraulic dredging has the potential to capture small fish and aquatic invertebrates in the flow of water and entrain them along with dredge materials being suctioned. NorthernStar proposes to use a cutterhead pipeline dredge to remove the sediments in the ship berth and maneuvering area.

The two types of mechanical dredges used in the Columbia River area are clamshell dredges and dipper dredges. A dipper dredge is basically a barge-mounted power shovel. Dipper dredges are best suited for excavating hard, compacted materials such as glacial till, stone, or blasted rock. Although they can be used to remove softer bottom sediments, the action of this type of equipment may cause considerable sediment disturbance and resuspension of fine-grained material. With mechanical dredging, mobile aquatic species such as fish would be less likely to be entrained with the dredged materials compared to hydraulic dredging.

A clamshell dredge consists of a crane with a cable attached to a clamshell bucket. Clamshell dredges can be used in tight quarters or shallow areas. Studies by the COE indicate that clamshell dredging generally results in greater sediment resuspension than other forms of dredging (e.g., hydraulic cutterhead dredges) (COE, 1988). Clamshell and dipper dredges both use barges or scows to haul the dredged material to placement areas. The bottoms of these barges or scows are generally designed to be opened, whereby the dredged material is dropped to the river bed or seafloor at the placement area. Typical production dredging with these two methods includes multiple barges or scows and tugs so that production can be maintained while full barges are towed to the placement site(s). The production rate is dependent upon several factors including dredged material characteristics, bucket size, and the efficiency of exchanging the barges or scows. Mechanical dredging would typically not be cost effective compared to hydraulic cutterhead pipeline dredging when the dredged material placement site is less than 5 to 8 miles from the dredging area.

3.1.9.2 Dredged Material Placement Alternatives

NorthernStar proposes to place up to the full amount of dredged material from the ship berth and maneuvering area (700,000 cubic yards) at the LNG terminal site, and any material not placed at the terminal site would be placed at the Wahkiakum County Sand Pit site on Puget Island. Other alternatives considered for dredged material placement include additional upland placement sites, Columbia River placement, and ocean placement. Table 3.1.9-1 lists the various dredged material placement alternatives, the associated dredging method, and a summary of potential advantages and disadvantage for each alternative. A detailed discussion of the alternatives follows.

Upland Placement

Available designated upland dredged material placement sites are limited along the lower Columbia River. The two closest are Bradwood Landing itself and Tenasillahe Island.

The Bradwood Landing site is designated as a dredged material management site on the Clatsop County Comprehensive Plan. Between 1966 and 2002, the COE placed almost 900,000 cubic yards of material from maintenance dredging of the Columbia River navigation channel at the Bradwood Landing site. NorthernStar proposes to place up to 700,000 cubic yards of material dredged from the Columbia River during creation of the ship berth and maneuvering area at Bradwood Landing. The material would be used to raise the grade of the site in preparation for construction of the onshore components of the LNG terminal.

Tenasillahe Island is located directly across Clifton Channel from the Bradwood Landing site and would be close enough that cutterhead pipeline dredging could be used. The island has been designated as a dredged material placement site for Columbia River improvement and maintenance projects. Based on consultation with the COE, ODSL, and the Port of Portland, this placement site would not be available for material from the Bradwood Landing Project. Available space for additional dredge disposal on the eastern end of the island has already been committed to other future projects; the rest of the island is protected as part of the Julia Butler Hansen National Wildlife Refuge (JBHNR). Tenasillahe Island has therefore been eliminated from further consideration as an alternative dredge disposal location for the Bradwood Landing Project. No other upland placement sites were identified that would be close enough to the Bradwood Landing site to be reasonable, practicable alternatives.

TABLE 3.1.9-1			
Dredged Material Placement Alternatives			
Placement Alternative	Primary Dredging Methodology	Advantages	Disadvantages
Upland Placement			
Bradwood Landing	hydraulic cutterhead pipeline	Proximity of site; already designated a dredged material placement area; could accommodate entire volume; most cost effective alternative.	Not an environmentally beneficial use. Sediment is removed from the river system.
Tenasillahe Island	hydraulic cutterhead pipeline	Proximity of site, already designated a dredged material placement area.	Not an environmentally beneficial use. Sediment is removed from the river system. Site is reserved for Columbia River channel and maintenance projects and not available for the Bradwood Landing Project.
Columbia River Placement			
Flow-Lane: Price Island and Brookfield Reach	hydraulic hopper or cutterhead pipeline	Beneficial use; sediments remain in river system.	Dredging area configuration is not suited for hopper dredge, which would be required for more distant placement sites. Minor impact on benthic communities. Permitting for in-water placement is more rigorous than for upland placement.
Scour Holes: Welcome Slough and Pancake Point	mechanical clamshell	Proximity of site; beneficial use; cost effective.	Could only accommodate up to 30 percent of material. The COE may fill sites first. Placement area is within designated salmonid critical habitat and EFH for coho and Chinook salmon.
Ocean Placement			
Shallow Water	mechanical clamshell	No significant environmental concerns provided the sediments to be dredged pass required testing. Could accommodate entire volume.	Sediment is removed from the river system. Distance of site results in relatively high cost. Requires permit under section 103 of the Marine Protection, Research, and Sanctuaries Act (MPRSA).
Deepwater	mechanical clamshell	No significant environmental concerns provided the sediments to be dredged pass required testing. Could accommodate entire volume.	Not an environmentally beneficial use. Sediment is removed from the river system. Distance of site results in relatively high cost. Requires permit under section 103 of the MPRSA.
Beach Nourishment			
Wahkiakum County Sand Pit on Puget Island	hydraulic cutterhead pipeline	Proximity of site; beneficial use; could accommodate a significant volume.	Placement area is within designated salmonid critical habitat and EFH for coho and Chinook salmon. Additional post-placement handling costs. Wahkiakum County has not yet obtained permits.

Columbia River Placement

The lower Columbia River is sediment deficient because upstream dams limit downstream movement of sediment. Consequently, placing the dredged material at another location in the river can have environmental benefits, such as counteracting shoreline and beach erosion. On the other hand, such actions can affect water quality, sediment transport, and water circulation, which in turn can have potential impacts on fisheries and biological communities. It follows that the permitting process for in-water placement of dredged materials is more rigorous and requires detailed testing and analysis of the potential environmental impacts of the proposed placement alternative. NorthernStar evaluated two types of in-water placement sites in the Columbia River, flow lanes and scour holes.

Flow Lanes

Flow-lane placement sites are located in or adjacent to the Columbia River navigation channel at depths generally from -50 to -65 feet CRD. Flow-lane placement sites are used by the COE for the Columbia River channel improve project. The locations of these sites vary from year to year depending on the condition of the channel. Placement of dredged material at a flow-lane site would raise the bottom elevation from 2 to 6 feet, depending on the location. This rise in the river bottom would not be expected to cause significant changes in water circulation, current pattern, water fluctuation, or water temperature. The dredged material would be similar in characteristics to the existing sediments. Flow-lane placement is used in areas where no other alternatives are available or where the quantity of material to be dredged is too small to warrant use of a cutterhead pipeline dredge that would be necessary for upland disposal. Flow-lane placement would not have a significant impact on aquatic resources because benthic invertebrate productivity is generally low in the deeper channel areas.

NorthernStar assessed two potential flow-lane sites that are located downstream of the Bradwood Landing site and would require use of a hopper dredge or bottom-dump barge, based on the distance from the dredging area. The Price Island site is located immediately north of the navigation channel at CRM 34.8 (see figure 3.1.9-1). NorthernStar determined that existing pile dikes at this location would present an operational safety hazard for dredge vessels and the Price Island site was not considered further. The Brookfield Reach site is located north of the navigation channel at CRM 30.5. Because of the distance between the dredging area and the Brookfield Reach site, which would require the use of a hopper dredge or bottom-dump barge, this alternative was also eliminated from further consideration.

Scour Holes

In addition to flow lanes, NorthernStar identified two scour holes locations as possible dredged material placement sites in the Columbia River. Currently, Wahkiakum County is in the process of obtaining a permit to place clean sands in two scour holes, Pancake Point and Welcome Slough, located along the southwestern side of Puget Island (see figure 3.1.9-1). While Wahkiakum County expects to receive sands from the COE as part of Columbia River navigation channel improvement or maintenance projects, it may consider receiving material from other sources. The Welcome Slough scour hole, located at CRM 40.5, covers 2.3 acres. The Pancake Point scour hole, at CRM 43.6, covers 6.1 acres. Currently, the bases of the scour holes reach depths of -90 feet CRD. A total of 192,000 cubic yards of material will be required to bring the riverbed elevation up to the desired elevation of -20 feet CRD. Supplemental material will be required over time to maintain this level.

The scour-hole sites could be used for up to 30 percent of the dredged material from the ship berth and maneuvering area if the space is still available when the dredging for the Bradwood Landing Project begins. The material would need to be clean sand. The scour holes may also be options for placement of material generated during maintenance dredging at the LNG terminal.

Ocean Placement

Ocean placement of dredged materials beyond the 3-mile state waters boundary requires a permit under section 103 of the Marine Protection, Research, and Sanctuaries Act (MPRSA). Such placement is only allowed if no other reasonable alternatives are available, and the material must pass specific testing requirements.

Figure 3.1.9-1
Bradwood Landing Project
 Dredged Material Placement Site Alternatives

0 3,500 7,000 10,500 14,000 Feet

The EPA has designated two open water dredged material placement sites offshore of the mouth of the Columbia River as part of the Columbia River Deepening Project. The first is a shallow water placement area located approximately 40 miles from the Bradwood Landing site. The site is a near-shore dispersive environment where material is expected to disperse into the littoral (beach) zone after placement. This placement area may be capable of accommodating all of the proposed dredged material from the Bradwood Landing Project. The second ocean placement site is a deepwater placement area located south of the Columbia River and 47 miles from the Bradwood Landing site. This placement area was selected to avoid biologically diverse areas and has enough capacity to be useable for at least 50 years.

Because of the distance of the ocean placement alternatives from the dredging area, a mechanical clamshell dredge would be used and the dredged material would be transported by bottom-dumping barges or scows to the placement site. The long distances, particularly for the deepwater placement area, needed to transport the dredged material make these placement alternatives the most costly, and they were eliminated from further consideration.

Beach Nourishment

Beach nourishment provides a beneficial use for dredged material that consists of clean sands. Based on consultation with Wahkiakum County, NorthernStar initially identified several beaches along Puget Island that would benefit from a beach nourishment project. Generally, beach nourishment projects entail placing dredged materials on a beach and in the adjacent aquatic areas. After the material has been placed, the beach must be graded at a uniform and gentle slope to minimize fish stranding problems and provide a safe beach. The dredged material must closely match the sediment composition of the eroding beach and be relatively free of contaminants. Costs for the beach nourishment alternative would be comparable to the Columbia River placement options plus some additional costs for grading and contouring.

Based on a feasibility study, the Wahkiakum County Sand Pit site was selected as a second proposed dredged material placement site along with the LNG terminal site for sediments dredged during construction of the ship berth and maneuvering area. The Sand Pit site is located on the northwest point of Puget Island across the Columbia River navigation channel from the Bradwood Landing LNG terminal site (see figure 3.1.9-1). The shoreline located between the Wahkiakum County Sand Pit and the federal navigation channel is subject to a combination of ship wakes, wind, and tidal effects that are currently eroding sand from the river beach at a rapid rate. Dredged material was most recently applied to the beach area in 2001 to mitigate the erosion.

Dredged material from the Bradwood Landing site would be placed within the existing upland settling basin at the Sand Pit site through a pipeline using a cutterhead pipeline dredge. Once drained, the sand would be moved from the settling basin and distributed by earthmoving equipment along the eroding shoreline and pushed into scour holes adjacent to the shoreline. The material would be dispersed as evenly as possible to avoid creating mounds. Furthermore, the beach would be graded to a minimum steepness of 10 to 15 percent to prevent the possibility of creating areas where fish could be stranded by wave action. No riparian vegetation is present that would be disturbed by the placement activities and no emergent vegetation was observed in the beach area. Up to 20,000 cubic yards of the dredged sand would be left within the settling basin to be used by Wahkiakum County for public projects. However, this alternative would only be viable if Wahkiakum County could successfully renew its permit for operation of the Sand Pit site. Wahkiakum County is currently seeking a permit to receive 205,000 cubic yards of material for beach protection at the Sand Pit site. Currently, it is uncertain when, or if, Wahkiakum County could obtain that permit. Project dredge material would be placed at the Sand Pit site up to the maximum permitted amount available at the time of dredging.

NorthernStar proposes to place approximately 80,000 cubic yards of material generated during maintenance dredging once every approximately 2 to 4 years at the Wahkiakum County Sand Pit site or another approved dredged material disposal site. Each round of maintenance dredging would take about 2 weeks and would be accomplished using a cutterhead suction dredge if placement is at the Sand Pit site. If a different dredge material disposal site is used, a clamshell/barge or hopper dredge would be necessary.

3.2 COAST GUARD ALTERNATIVES

On February 28, 2007, the Coast Guard issued its WSR to the FERC (Appendix G). This report indicated that the Columbia River waterway may be suitable for LNG marine traffic if certain safety and security measures are adopted. After the final EIS is produced, the Coast Guard will complete its review and issue an LOR to address the suitability of the waterways for LNG carrier transport.

The Coast Guard's proposed action is to issue an LOR finding the waterway suitable for LNG marine traffic with conditions. These conditions would include the safety and security measures described in the WSR, as discussed in detail in section 4.11.5.5. Among these measures are: 1) establishment of a 500-yard moving safety/security zone during LNG vessels' transit of the waterway, including the requirements for one-way LNG marine traffic along certain portions of the waterway such as at turns and for a 200-yard security zone around the LNG vessel when it is moored at the LNG terminal; 2) a 50-yard security zone around the LNG terminal when there is not a vessel at the dock; 3) an annual review by NorthernStar of its WSA to evaluate if any conditions in the waterway have changed that would require issuance of a new LOR and submit the annual review to the COTP for his/her review and issuance of a new LOR if necessary; 4) the requirement that LNG vessels must board a pilot(s) at least 5 miles before the CR Buoy and for at least the first 6 months, at least two pilots must be on board throughout the transit and that at least two tugs escort the vessel along the waterway with a third to assist with turning and mooring; 5) implementation of a Coast Guard-approved *LNG Vessel Transit Management Plan*; 6) improvements to the Columbia River's Vessel Traffic Information System; and 7) availability of Coast Guard as well as other safety and security resources to implement the above security measures. If these conditions to the LOR are imposed, the potential for accidental releases or releases from terrorist attacks would be minimized.

Reasonable alternatives to the Coast Guard's proposed action with conditions include: 1) issuance of an LOR finding the waterway suitable for LNG marine traffic without conditions; and 2) issuance of an LOR finding the waterway not suitable for LNG marine traffic (no action alternative). The Coast Guard's preferred alternative is to issue an LOR finding the waterway suitable for LNG traffic with certain conditions.

If the Coast Guard finds the waterway not suitable, project-related environmental impacts resulting from LNG marine traffic would not occur. However, the no action alternative would mean that the project objectives would not be met. If LNG carriers are not able to transit up the Columbia River to the import terminal, then the Bradwood Landing Project could not supply new sources of natural gas to meet projected future demands in the Pacific Northwest. As discussed in section 3.1.1, there are a number of environmental consequences that may result as potential users seek other sources of energy to replace the natural gas not imported in the case of a no action alternative where the Bradwood Landing Project is not constructed and operated.

A reasonable alternative to the Coast Guard action of issuing an LOR, which finds the waterway suitable for LNG marine traffic with certain conditions, is to issue an LOR without any conditions. With this alternative, some of the economic effects of the conditions would be lessened. For example, the cost to the Coast Guard for escort patrols would not be required if the condition of establishment of a moving

safety/security zone was not imposed; the cost to the facility for additional WSAs would not be required if the condition of requiring an annual review of the WSA was not imposed; the cost for vessel traffic information system improvements would not be required if the condition for additional equipment and personnel was not imposed; the cost to the facility for tug assistance would not be required if this condition was not imposed; and the cost for shoreline security patrols would not be required if the condition for a security zone around the facility was not imposed.

However, the potential for adverse environmental effects would be greater if conditions were not imposed. There would be an increase in the potential for adverse environmental effects from collisions, allisions, and terrorist threats if: 1) moving and stationary safety zones were not required; 2) the WSAs were not updated with the most current information on changes in the waterway; 3) vessel traffic information system improvements were not required; 4) an *LNG Vessel Transit Management Plan* was not implemented; and 5) the Coast Guard lacks resources to ensure implementation of the safety zones and other security measures.

The preferred alternative of issuing a conditional LOR would allow LNG marine traffic to reach Bradwood Landing and provide a new source of imported natural gas for customers in the Pacific Northwest to meet future demands. The conditions in the LOR would reduce adverse impacts associated with LNG marine traffic in the waterway by providing mitigation measures for safety and security of vessels in transit.

4.0 ENVIRONMENTAL ANALYSIS

The environmental consequences of constructing and operating the proposed Bradwood Landing Project would vary in duration and significance. Four levels of impact duration were considered: temporary, short term, long term, and permanent. A temporary impact generally occurs during construction with the resource returning to preconstruction condition almost immediately afterward. A short-term impact could continue for up to 3 years following construction. Impact was considered long term if the resource would require more than 3 years to recover. A permanent impact could occur as a result of any activity that modifies a resource to the extent that it would not return to preconstruction conditions during the life of the project. We considered an impact to be significant if it would result in a substantial adverse change in the physical environment.

In this section, we discuss the affected environment, general construction and operational impacts, and proposed measures to avoid, reduce, or mitigate impacts. Our discussion encompasses project-related impacts associated with the construction and operation of the LNG import terminal and the sendout pipeline. We also discuss the potential impacts on resources along the waterway for LNG marine traffic, extending to the Zones of Concern,¹ resulting from an accidental or intentional release of LNG from a ship in transit or at dock at the LNG terminal.

NorthernStar, as part of its proposal, agreed to implement certain measures to avoid, minimize, or mitigate impacts on specific resources. We evaluated NorthernStar's proposed measures to determine if they would adequately mitigate impacts. In cases where we felt that NorthernStar's proposed measures were less than adequate, where no mitigation measures were proposed, or where final design details requiring Commission review have yet to be developed, and to ensure that appropriate design requirements are implemented, we have added our recommendations to reduce impacts. These additional measures appear as bulleted, boldfaced paragraphs in the text. We will recommend that these measures be included as specific environmental conditions attached as an appendix to the Commission Order authorizing this project.

This EIS represents our independent analysis of the proposed action and the data submitted by NorthernStar. It includes the review of the proposal by the federal agencies cooperating in the production of the EIS: the Coast Guard and COE. Conclusions in this EIS are based on our analysis of environmental impacts, given the following assumptions:

- NorthernStar would comply with all applicable laws and regulations;
- the proposed facilities would be constructed as described in section 2.0 of this document; and
- NorthernStar would implement the mitigation measures included in the application and supplemental filings to the FERC.

¹ The "Zones of Concern" are described in Enclosure 11 of the Coast Guard's NVIC 05-05. These zones are based on the report entitled, Guidance on Risk Analysis and Safety Implications of a Large LNG Spill Over Water, produced by the U.S. Department of Energy, Sandia National Laboratories (2004). This "Sandia Report" and the Zones of Concern are discussed in more detail in section 4.11.5.3 of this EIS.

4.1 GEOLOGY

4.1.1 Regional Geologic Setting

The geology of the Pacific Northwest region is dominated by the Cascadian Subduction Zone (CSZ) driven by the convergence of the Juan de Fuca plate beneath the North American plate. The oblique northeast-trending subduction of the Juan de Fuca plate relative to the North American plate has created a seismically active margin, producing faulting, folding, and volcanic activity. The CSZ contains four distinct seismotectonic provinces: the Cascadia Accretionary Wedge, Rotating Block, Uplift and Transpression Zone, and Cascades (Wells et al., 1998). The proposed Bradwood Landing Project would be located within the Rotating Block, which includes the Oregon Coast Range and the Willapa Hills physiographic provinces.

The Coast Range province is bound by the western edge of the Willamette Valley to the east, the continental shelf to the west, the Columbia River to the north, and the Coquille River to the south. The province measures approximately 200 miles north to south, and ranges from 30 to 60 miles wide from east to west. Elevations of the Coast Range extend from sea level to an average crest elevation of 1,500 feet (Orr and Orr, 2000).

The Willapa Hills province is a portion of the Coast Range that extends north of the Columbia River into Washington. The Willapa Hills province extends west to the Pacific Ocean, southeast to the southern Cascades, northeast to the Puget Lowlands, and north to the Olympic Mountains (Livingston, 1978). The province measures nearly 100 miles north to south and approximately 80 miles east to west. Elevations of the Willapa Hills province range from sea level to approximately 3,100 feet.

Rock units of the northern Coast Range and the southern Willapa Hills physiographic provinces consist primarily of volcanic accreted terrain and tectonically uplifted sedimentary rocks. Portions of the provinces are covered with the Columbia River Basalt Group (CRBG), large scale basalt flow units originating from volcanic vents to the east. The CRBG units are exposed in 200-foot-high cliffs immediately southeast of the proposed LNG terminal. The most recent geologic units consist of stream deposited alluvium in the low-lying areas of the provinces (Orr and Orr, 2000).

Most of Oregon was below the surface of the Pacific Ocean at the beginning of the Tertiary Period, approximately 67 million years ago (mya). Topography in the western portions of Oregon and Washington began to take shape in the Tertiary Period as the Juan de Fuca plate accreted a series of volcanic islands onto the North American Continent. In addition, this tectonic activity uplifted the region, creating the mountains of the Coast Range. This regional uplift exposed the sedimentary rocks of the Coast Range in the middle to late Miocene (17 to 10.8 mya) (Orr and Orr, 2000; Newton and Van Atta, 1976).

During the same period of time, the Wanapum and Frenchman Springs members of the CRBG flowed into the low-lying areas along the Columbia River and the northern Oregon coast (Walsh, 1987). These basalt flows created rock units that are up to 500 feet thick and are believed to have formed intrusive dikes and sills in unconsolidated marine sediments of the Coast Range (Orr and Orr, 2000; Niem and Niem, 1985).

In recent time, the coastal regions of Oregon and Washington have continued to deform as a result of the Juan de Fuca plate subducting beneath the North American plate. Data suggests the coast range in the vicinity of the pipeline is deforming in a tilting manner, with uplift in the vicinity of Astoria, Oregon occurring at a rate similar to the depression rate in the vicinity of Rainier, Oregon (Orr and Orr, 2000). While published vertical deformation rates vary greatly, vertical uplift rates west of the LNG

terminal are believed to be on the order of 1 inch per 30 to 130 years (Orr and Orr, 2000; West and McCrumb, 1988). One study suggests the vertical deformation rate near Tillamook Head, Oregon is approximately 1 inch per 13 years (Kelsey et al., 1994).

The Columbia River has formed erosional features along the northern Coast Range and Willapa Hills exposing cliffs in the basalt and sedimentary rock units, and depositing alluvium on the order of 100 feet thick (Niem and Niem, 1985). Table 4.1.1-1 lists the stratigraphic units that underlie the Bradwood Landing Project area.

4.1.2 Waterway for LNG Marine Traffic

4.1.2.1 Stratigraphy

Rock units along the Oregon side of the waterway from east to west between the LNG terminal site and Youngs River are: the middle Miocene Gnat Creek Formation, consisting of nonmarine sandstones and mudstones; and the middle to lower Miocene Astoria Formation, consisting of deep marine mudstones and arkosic sandstones (Niem and Niem, 1985). Unconsolidated deposits along the waterway generally consist of Quaternary sand bars; islands; and estuarine clay, silt, and fine sand in low-lying coastal areas in and along the Columbia River. Unconsolidated deposits west of about Tansy Point consist of Quaternary dune sand and beach sand. Some of these deposits represent fill from dredged material placement. The Geologic Map of Washington (Schuster, 2002) also depicts primarily Tertiary sedimentary rocks along the Washington side of the waterway, with lower Tertiary volcanic rocks between Megler and Chinook.

4.1.2.2 Mineral Resources

Mineral resources in the area adjacent to the waterway include sand and gravel, as well as basalt rock, which can be crushed for construction material (Schlicker et al., 1972). With the possible exception of increased shoreline erosion (see section 4.1.2.3), LNG marine traffic would not effect mineral resources along the waterway. Because the LNG carriers would be restricted to the established navigation channel, where any mineral resource development is already precluded, the LNG marine traffic associated with the Bradwood Landing Project would not have an impact on future development of mineral resources.

4.1.2.3 Geologic Hazards

The only geologic hazard that would affect or be influenced by the LNG marine traffic along the waterway is shoreline erosion. The effect of LNG carriers on shoreline erosion at and in the vicinity of the proposed LNG terminal is discussed in section 4.1.3.3. Shoreline erosion along the remainder of the waterway is discussed below.

Shoreline erosion along the Columbia River is caused by river currents, wind waves, and ship wakes. River currents can erode banks and carry sediment away from the shoreline. Wind waves and ship wakes can also erode banks but they only move sediment locally within the shallow water zone near the shore. The amount of erosion that occurs at a particular location depends on the interaction between the eroding forces of river currents and waves and the resisting forces of the river bank (COE, 1999).

The Columbia River's natural shoreline consists of basalt outcrops and sand, silt, and clay deposits. Most of the natural shoreline is resistant to erosion, there has been little change in the river's location over the last 6,000 years. Erosion of the natural shoreline has only occurred at a few isolated locations. One such location is the upstream end of Price Island (CRM 34-35) where river currents are eroding a 1-mile stretch of bank at a rate of about 10 feet per year (COE, 1999).

TABLE 4.1.1-1

Generalized Stratigraphy in the Proposed Bradwood Landing Project Area

Age	Formation / Estimated Thickness	Aquifer	Lithology	Water Bearing Properties
Recent	Fill and spoil Variable	NA	Predominantly poorly graded fine sand with occasional silt, gravel, and construction debris.	NA
Quaternary Holocene to Pleistocene	Alluvium 100 feet	Quaternary sediment deposits	Unconsolidated flood plain deposits of clay, silt, sand, and basalt gravel.	Yields small to large supplies of water of variable quality sufficient for municipal, domestic, and stock use.
	Landslide debris Variable		Unconsolidated sand, silt, and clay.	Yields small supply of water, but is limited in aerial extent.
	Terraced sediments 25-100 feet		Silt, sand, and gravel of diverse compositions and origins, such as proglacial outwash, older alluvium, lahars, and uplifted coastal marine and estuary deposits.	Yields moderate to large supply of water, but is limited in aerial extent. Sufficient for municipal, domestic, and stock use.
Tertiary Middle to Upper Miocene	Saddle Mountain Basalt 300 feet	Undifferentiated	Fine grained, sparsely phyric tholeiitic and olivine flood basalt with sedimentary interbeds of tuffaceous sandstone, siltstone, and pumiceous conglomerate.	Rock formation yields small amounts of water, but joints and fissures within rock and coarse grained interbeds can produce large quantities of freshwater suitable for public, domestic, and stock use.
Tertiary Middle Miocene	Gnat Creek Formation 700 feet	Tertiary Rocks of the Coast Range	Massive, coarse to fine-grained, arkosic sandstone to siltstone.	Yields small to moderate supplies of water of variable quality sufficient for domestic and stock use.
Tertiary Middle Miocene	Wanapum Basalt, Frenchman Springs Member 500 feet	Undifferentiated	Sub-aerial, fine to medium basalt flows and associated pillow basalt breccias.	Rock formation yields small amounts of water, but joints and fissures within rock and coarse grained interbeds can produce large quantities of freshwater suitable for public, domestic, and stock use.
Tertiary Middle Miocene	Miocene Sandstone Interbed 200 feet		Arkosic, fine-grained sandstone interbedded between Frenchman Springs and Grande Ronde Formations.	
Tertiary Middle Miocene	Grande Ronde Basalt 500 feet		Mostly sub-aerial, columnar-jointed basalt flows and associated basal basalt breccias and pillow lavas.	
Tertiary Middle to Upper Eocene	Grays River Basalt Unknown		Aphyric to sparsely phyric basalt flows, flow breccias, aquagene tuff, pillow basalt, and interbedded siltstone and sandstone.	
Tertiary Eocene	Cowlitz Formation 2,000 feet		Very fine to coarse grained feldspathic sandstone, laminated siltstones, tuffaceous siltstone, and lignite.	
NA	Not Applicable			
Sources:	Beaulieu, 1973; Myers, 1970; Newton and Van Atta, 1976; Niem and Niem, 1985; McFarland, 1983; URS, 2005; Walsh et al., 1987.			

About half of the Columbia River shoreline between CRMs 21 and 106 consists of material deposited in the course of earlier dredging. These dredged material placement sites are highly susceptible to erosion by river currents and waves. The rate of erosion at these sites depends on river bathymetry, time since placement of dredged materials, proximity to the navigation channel, wind fetch, current pattern, and the amount and type of bank protection (COE, 1999).

The only element of the proposed project with the potential to affect the rate of shoreline erosion along the waterway is the passage of LNG carriers. Little information is available on the degree to which erosion of the Columbia River shoreline can be attributed to ship wakes. A 1990 study measured erosion rates at three locations, Price Island (CRM 34-35), Puget Island (CRM 38-44), and Gull Island (CRM 55), in the first year after placement of dredged material and concluded that 4 to 24 percent of the erosion was attributable to ship wakes (COE, 1999).

Large waves contain more energy than small waves and thus, have a greater ability to erode river banks. The size of waves produced by a vessel passing through a channel depends on the characteristics and speed of the vessel and the characteristics of the channel. An analysis undertaken for the COE concluded that the size of ship-produced waves in the Columbia River depends on the blockage ratio, which is the ratio of the cross-sectional area of the ship to that of the channel (COE, 2003).

NorthernStar commissioned a study of wave generation by LNG carriers, which compared wave generation by an Aframax tanker, representative of a large ship that works the Columbia River, with an LNG tanker. The Aframax tanker had an overall length of 761.2 feet, a beam or breadth of 137.8 feet, a loaded draft of 39.7 feet and a submerged or blockage area of 5,471 square feet. The LNG carriers would have an overall length of 944.6 feet, a beam of 148.3 feet, a loaded draft of 38.4 feet and a submerged or blockage area of 5,695 square feet. The study indicated that waves generated by LNG carriers would be only slightly larger than those generated by an Aframax tanker operating at the same speed.

The proposed project would only increase ship traffic along the reach of the river between its mouth and the LNG terminal site by about 7 percent; however, deep-draft vessel traffic would increase by about 25 percent. The LNG carriers would be larger than most of the deep-draft ships currently using the Columbia River, although larger ships are expected to transit the Columbia River once the Columbia River Channel Improvement Project is completed. Because the blockage ratio of the LNG carriers would be greater than that of most of the deep-draft ships currently traveling the Columbia River, the LNG carriers could potentially produce larger waves than most of the current ships operating at the same speed. LNG carriers would travel at speeds between 8 and 12 knots while on the Columbia River.

In summary, the degree to which current ship traffic affects shorelines along the waterway is difficult to quantify due to the various other factors which contribute to shoreline erosion and accretion processes. Therefore, it is difficult to determine what additional impacts on shorelines the proposed LNG marine traffic would contribute. The FERC staff continues to study this issue and additional analysis regarding shoreline erosion will be included in the revised BA. The potential impacts of shoreline erosion on wetlands are discussed in section 4.4.1.1 and on aquatic resources in section 4.5.1.1.

4.1.2.4 Paleontological Resources

Although LNG marine traffic could contribute to the shoreline erosion caused by ship traffic in general, such erosion mainly affects unconsolidated recent sediments, which would not contain any significant paleontological resources. Therefore, LNG marine traffic would not have an impact on paleontological resources.

4.1.3 LNG Terminal

4.1.3.1 Stratigraphy

The Bradwood Landing LNG terminal site is currently covered by fill and native alluvium. Fill was originally placed at the site by the COE around 1930 to raise the land prior to construction of the former saw mill and town of Bradwood. After the mill was closed, between 1966 and 2002 the COE placed at Bradwood approximately 873,000 cubic yards of material dredged while maintaining the Columbia River navigation channel (AMEC, 2005). Recent alluvial deposits are present in the southwestern portion of the site along the banks of Hunt Creek. The site is relatively flat and level, with the exception of the dredged sand fill stockpiles, which are several feet in height. The average elevation of the site is approximately 14 feet above mean sea level (msl). The stratigraphic units at the proposed LNG terminal are briefly described below.

Fill. Fill material at the proposed Bradwood Landing LNG terminal site is mostly comprised of poorly graded fine sand with occasional silt, and gravel. One of the geotechnical soil borings placed at the site by NorthernStar indicates possible fill occurring from the surface to a depth of about 10 feet. The other soil borings do not distinguish subsurface fill material (URS Corporation (URS), 2005). The dredged material occurs in stockpiles at least 15 feet high.

Alluvium. Alluvium underlies the fill at the proposed LNG terminal and is present at the ground surface along the Columbia River. The alluvium consists of unconsolidated sands, silts, and clays that were stream deposited during recent geologic time as sorted or semi-sorted sediment in the stream bed, on its flood plain or delta, or as a cone or fan at the base of a mountain slope (Niem and Niem, 1985; Beaulieu, 1973).

The alluvial deposits at the proposed LNG terminal can be further broken down into the following stratigraphic units, based on soil borings conducted at the site (URS, 2005):

- *Near Surface Fine-Grained Soils.* A 20- to 25-foot-thick layer of silts, clays, and silty sands is present at the surface. These deposits represent the former surficial soils deposited on the Hunt Creek floodplain and consist predominantly of soft to clayey silts, elastic silts, and silty clays with interbedded layers of loose to medium dense silty sands and sandy silts.
- *Upper Alluvial Sand Sequence.* A 50- to 60-foot-thick layer of alluvial sands underlies the surficial floodplain deposits and consist predominantly of relatively uniform poorly graded sands and silty sands deposited by the Columbia River.
- *Estuarine Silts and Clays.* A thick package of relatively uniform silts and elastic silts ranging in thickness from 50 to 60 feet underlies the upper alluvial sands. These silts range from very soft to stiff in consistency and locally exhibit organics and interbeds of sandy and clayey silts as well as lean clays. This unit likely represents an estuary that formed adjacent to the ancient Columbia River. When sea level rose at the close of the last ice age, this estuary was buried by modern alluvial deposits.
- *Lower Alluvial Sand Sequence.* A 25- to 45-foot-thick layer of alluvial sands was encountered below the estuarine silts in the borings advanced to depths of 150 feet or greater at the site. These sediments were deposited by the ancient Columbia River when global sea levels were much lower than at present and consist predominantly of poorly graded sand with silt and silty sands.

Gnat Creek Formation. During periods between flood basalt eruptive sequences in the middle Miocene epoch, local streams and the ancient Columbia River system deposited micaceous and carbonaceous arkosic sandstone with minor siltstone beds known as the Gnat Creek Formation, which was eventually capped by subsequent flows of flood basalts. The Gnat Creek Formation unconformably overlies the Frenchman Springs Member of the CRBG, is overlain west of the proposed LNG terminal site by the Pomona Member of the CRBG, and can occur in thickness up to 650 feet (Niem and Niem, 1985). In outcrop the Gnat Creek Formation consists of a light brown, very weak, moderately to highly weathered friable sandstone that is poorly bedded. Exposures of the Gnat Creek Formation are visible along the base of the cliffs immediately southeast of the proposed LNG terminal, as well as along road cuts east of the site entrance. Sandstones along these cuts are complexly interbedded with siltstone and some conglomerates. These exposures of the Gnat Creek Formation in the vicinity of the proposed LNG terminal site are relatively devoid of joints, cleavage, or evidence of shears or faulting (URS, 2006a).

Columbia River Basalt Group. The CRBG represents Miocene age flood basalts that erupted from feeder dikes and vents in Northeastern Oregon and Southeastern Washington during Miocene time (between 6 and 17 mya), eventually mantling over 63,000 square miles of the Pacific Northwest with basalt flows. Some of these flows traveled down the ancestral Columbia River channels, eventually reaching the Pacific coastline. At the proposed LNG terminal, basalt flows exposed in the cliffs south of the site can be traced from southeast of the site to the west and past Hunt Creek. The waterfall near the mouth of Hunt Creek spills over this basalt outcrop, which appears to pinch out a few hundred feet to the west of the waterfall. In outcrop the basalt is dark gray, strong to very strong, and is slightly to moderately weathered. Specific units encountered in the vicinity of the proposed LNG terminal are discussed below.

- *Wanapum Basalt.* Outcrops of the Frenchman Springs Member of the middle Miocene Wanapum Basalt formation are located in cliffs to the southeast of the proposed LNG terminal. The Frenchman Springs basalt is fine to medium-textured and can contain extensive areas of pillow basalt breccias. The Frenchman Springs Member is approximately 500 feet thick in the vicinity of the proposed LNG terminal (Niem and Niem, 1985).
- *Miocene Sandstone Interbed.* The Miocene Sandstone Interbed separates the Wanapum Basalt and the underlying Grande Ronde Basalt. The sandstone is arkosic, fine grained, and can occur in thicknesses of up to 200 feet. A small outcrop is present approximately 2 miles to the south of the proposed Bradwood Landing LNG terminal (Niem and Niem, 1985).
- *Grande Ronde Basalt.* The Grande Ronde Basalt formation is located at depth below the proposed LNG terminal. Like the Wanapum Basalt, the Grande Ronde Basalt is a middle Miocene member of the CRBG. However, the Grande Ronde Basalt is approximately 300,000 years older than the Wanapum Basalt. The Grande Ronde formation is sub-aerial, columnar jointed, and includes some areas of basalt breccias and pillow lavas (Niem and Niem, 1985).

4.1.3.2 Mineral Resources

NorthernStar conducted a data search to identify any mineral resources or mining activity within 1,500 feet of the LNG terminal. Data on file with the Oregon Department of Geology and Mineral Industries (DOGAMI) and the BLM indicate that one permitted rock quarry is within the specified search radius. This small quarry, referred to as the Bradwood Quarry, is located within the 411-acre parcel under option to NorthernStar (see figure 2.3.2-1). The quarry was permitted in 1984 as a potential source of

basalt for construction purposes, and the soil overburden was removed from an area of about one-half acre in size. The quarry has never been actively worked; however, the permit has been kept current.

The current landowner (Ken Leahy) possesses the permits for and mineral rights to the Bradwood Quarry. These rights and permits (including DOGAMI Permit No. 04-0067) would transfer to NorthernStar with the sale of the property. NorthernStar may use the quarry as a source of basalt rock to be crushed for sand and aggregate during site construction. NorthernStar would obtain all necessary additional permits (e.g., Clatsop County development permit and NPDES stormwater discharge permit) and comply with applicable regulations associated with further development of the quarry. Before operation of the LNG terminal, the quarry would be decommissioned and reclaimed in accordance with DOGAMI regulations. The reclamation plan would be submitted with the operating permit application. Accordingly, there would be no risk to the operation of LNG terminal from mining activities related to the Bradwood Quarry, such as blasting, or other mining related impacts. Further, because any below-grade quarry excavations would be filled with appropriate fill material to site grade during reclamation, as required by DOGAMI regulations, no subsidence, slumping, landsliding, or other ground failure would occur in the quarry area during operation of the LNG terminal.

4.1.3.3 Geologic Hazards

Potential geologic hazards that could impact the terminal and pipeline facilities of this project can be separated into short-term and long-term events or conditions. Short-term events include:

- soil mass wasting and rock slope failure;
- seismicity and faulting;
- soil liquefaction and lateral spreading;
- volcanism and lahars; and
- flooding, tsunamis, seiches, and landslide-induced waves.

Long-term events or conditions include:

- slope instability and inadequate load bearing capacity of soils;
- shoreline erosion;
- subsidence;
- karst features; and
- corrosive soils.

These geologic hazards, their potential to occur in the project area, and proposed mitigation measures, where applicable, are further described below for the LNG terminal and the general project area. Geologic hazards that are specific to the pipeline are discussed in section 4.1.4.3. Geologic hazards as they relate to the waterway for LNG marine traffic were addressed in section 4.1.2.3. In general, the risk of damage resulting from geologic hazards would be avoided or reduced by specific engineering design criteria, ground modification, other construction techniques, and operating procedures to be implemented by NorthernStar.

Soil Mass Wasting and Rock Slope Failure

Mass wasting and rock fall result from the natural process of gravity acting upon a block of material over time. Mass wasting refers to all soil-related slope failures, including landslides, slumps, and debris flows. Rock slope failures include slab failures, wedge failures, falls, and toppling.

The existing topography at the proposed LNG terminal site does not present any slope geometry that would likely result in a soil mass wasting event that could reach the terminal facility. Debris flows or landslides initiated within the Hunt Creek drainage would proceed northward through the wetlands and mitigation areas west of the terminal and could not reach the terminal facilities.

Rock slopes near the site are relatively flatly bedded. Accordingly, slab and wedge failures are not anticipated in the vicinity of the terminal. However, the basalt cliff located south of the site contains many discontinuous joints, presenting a potential rock fall or toppling hazard at the base of the cliff. The rock fall may be produced by toppling, block failure, or planar and/or wedge failure.

The risk of rock fall runout proceeding north of the proposed railroad track realignment is not considered likely due to the beneficial energy dissipation characteristics of the on-site soils as well as site geometry. The separation distance between the cliffs and the nearest LNG storage tank is about 250 feet, greater than likely rock fall runout distances. Moreover, the sand deposits at the base of the cliff have excellent energy dissipation characteristics, and the construction of the proposed 5-foot-high tertiary containment berm would prevent rocks that overcame the first two conditions from reaching the facilities.

In 1965, a landslide occurred approximately one-half mile upriver of the Bradwood Landing site. The landslide created a wave in the Columbia River that resulted in the loss of one life and property damage on a small portion of Puget Island (Wahkiakum County Eagle, 1965).

The *Washington State Hazard Mitigation Plan* (Washington Emergency Management Division, 2004) indicates that in the 1890s, a poorly documented, landslide-triggered wave near Cathlamet killed one person on Puget Island. As described above, landslides in the vicinity of the proposed LNG terminal would be unlikely to reach the terminal facilities. Tsunami risks are discussed below.

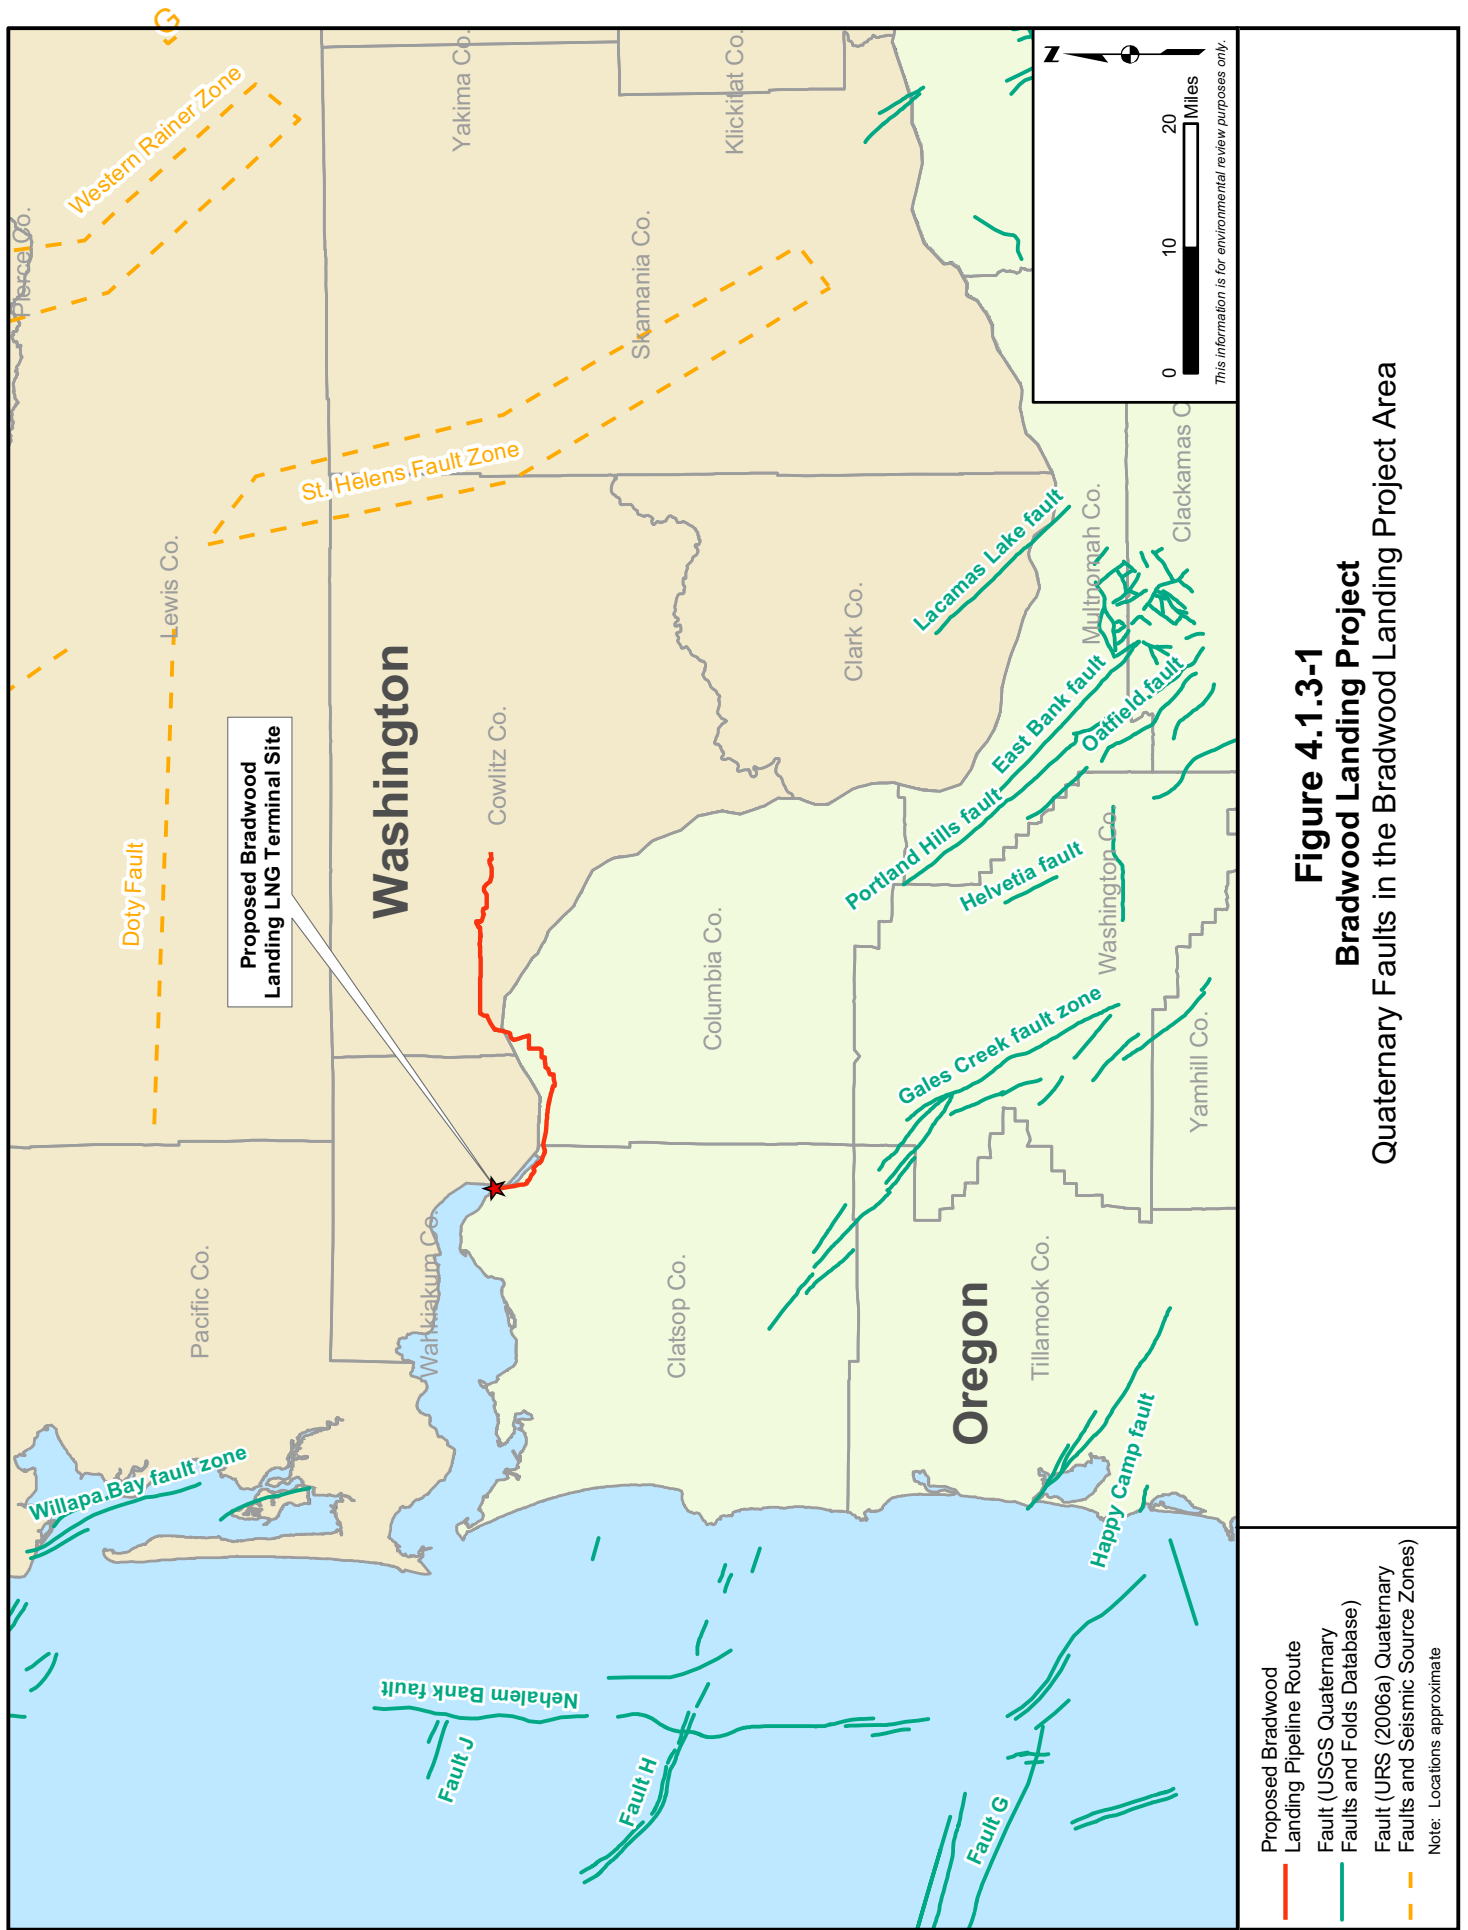

Seismic-Related Hazards

Potential seismic-related hazards include earthquakes, surface faulting, soil liquefaction, and related soil failures. The Pacific Northwest coastal region of the United States is a tectonically active region that has significant potential for seismic activity. Northwestern Oregon and southwestern Washington comprise an area of diffuse seismicity with a few areas of concentrated seismicity. The Portland area is the most seismically active area in Oregon (URS, 2006a). Most events are not associated with known faults. Figure 4.1.3-1 depicts Quaternary faults, primarily from the USGS Quaternary faults and folds database (USGS, 2006).

Significant earthquakes that have occurred in the project region are described in the seismic hazard analysis for the LNG terminal (URS, 2006a).² The most recent of these are the 1993 Scotts Mills earthquake (magnitude 5.6), the 1999 Satsop earthquake (magnitude 5.9), and the 2001 Nisqually earthquake (magnitude 6.8).

According to URS (2006a), the seismogenic crust, typically 15 to 20 kilometers thick, may be significantly thicker (20 to 30 kilometers) within the project area, resulting in fewer surficial faults in the region. URS (2006a) estimates that in the vicinity of the LNG terminal site, an earthquake with a magnitude of 7.0 or greater would be required to cause surface rupture. As such, deep seated faults could potentially exist in the project area without showing visible signs of faulting or deformation at the ground surface.

² URS's Final Report, Seismic Hazard Analysis for LNG Import Terminal, Bradwood, Oregon dated February 2006 is available on the FERC's website. Using the "eLibrary" link, select "General Search" from the eLibrary menu and enter the docket number, excluding the last three digits, in the "Docket Number" field (i.e., CP06-365 and CP06-366). Be sure to select an appropriate date range.

URS (2006a) found no evidence of active faults within 1 mile of the proposed LNG terminal site based on: 1) review of relevant literature; 2) examination of aerial photographs; 3) review of boring logs and cross sections; and 4) site reconnaissance. Review of geologic maps indicated only one potential fault within 2 miles of the site (Niem and Niem, 1985). Site reconnaissance revealed no evidence of ground rupture or faulting. The closest mapped Quaternary faults to the LNG terminal site are the Doty fault, approximately 27 miles to the north, and the Gales Creek fault zone, approximately 25 miles to the south (see figure 4.1.3-1). Based on these observations, URS concluded the potential for ground rupture at the Bradwood Landing LNG terminal is negligible.

Since 1980, when seismograph coverage became adequate to record and locate smaller earthquakes, seismicity has occurred at a moderate level within 30 miles of the proposed LNG terminal (URS, 2006a). The largest recorded event was a local Richter magnitude 3.7 earthquake that occurred in 1984 about 21 miles east of the site.

As discussed in URS (2006a), the CSZ has experienced no significant earthquakes in the historical period (i.e., since about 1850) (Weaver and Shedlock, 1996; Personius and Nelson, 2003), with the possible exception of the 1992 magnitude 7.0 Petrolia, California, earthquake that may have occurred on the interface or within the overriding plate. The absence of seismicity, as well as geodetic (e.g., Flück et al., 1997; Savage et al., 2000) and geologic (e.g., Atwater, 1987; Atwater et al., 1995; Clague, 1997) studies, indicate that the interface is locked and storing strain that is released in great earthquakes. Some geologic investigations on and offshore suggest that the CSZ is segmented and ruptures in approximately 8 to 8.5 magnitude earthquakes. However, the most recent event is believed to have ruptured the entire length of the subduction zone in an earthquake estimated by Japanese tsunami records at a magnitude of 8.7 to 9.2 (Satake et al.; 1996, 2003). Paleoseismic studies indicate a range of recurrence interval estimates for megathrust events along the CSZ, but the most complete studies suggest an average recurrence interval of about 500 years (e.g., Adams, 1990; Atwater and Hemphill-Haley, 1997; Goldfinger et al., 2003; Witter et al., 2003).

DOT Seismic Design Requirements (NFPA 59A-2001)

The seismic design requirements for LNG facilities are contained in the U.S. Department of Transportation regulations at 49 CFR Part 193, which adopts the seismic design provisions of the NFPA 59A (2001). NFPA 59A (2001) defines two levels of earthquake motions, the Operating Basis Earthquake (OBE) and the Safe Shutdown Earthquake (SSE). The OBE and SSE ground motions must be determined by site-specific evaluations and are defined in terms of 5 percent damped response spectra with the following probability levels:

The OBE ground motions at the site are defined as the lesser of:

1. ground motion with a 10 percent probability of exceedance within a 50-year period (475-year return period); or
2. two-thirds (2/3) of the Maximum Considered Earthquake (MCE) ground motion

In NFPA 59A (2001) the MCE is defined as future potential ground motion with a 2 percent probability of exceedance within a 50-year period (2,475-year return period) with deterministic limits.

The SSE ground motions at the site are defined as the lesser of:

1. 1 percent probability of exceedance within a 50-year period (4,975-year return period); or
2. 2 times the OBE.

These motions would be used as the basis for the earthquake-resistant design of the LNG facility, applied to the following limited specific list of critical safety-related structures, systems, and components per NFPA 59A (2001) 4.1.3:

1. LNG storage containers and their impounding systems;
2. system components required to isolate the LNG container and maintain it in a safe shutdown condition; and
3. structures and systems, including fire protection systems, the failure of which could affect the integrity of (1) or (2) above.

NFPA 59A (2001) specifies that the above-referenced structures, systems, and components must be designed to remain operable during and after an OBE, and must provide for no loss of containment capability of the primary container during and after an SSE. The facility design must also provide for the ability to isolate and maintain the LNG container during and after an SSE. After an SSE event, the container must be emptied and inspected prior to resumption of container filling operations. At a minimum, the impounding system must be designed to withstand an SSE while empty, and an OBE while holding the maximum operating volume of the LNG container. Seismic recording instrumentation is also required.

FERC Seismic Design Guidelines for LNG Facilities

There are areas where NFPA 59A (2001) does not provide specific seismic design requirements to enable a comprehensive philosophical approach to the overall seismic safety of an LNG facility. Consequently there can be a wide range of opinions by technical experts on how various requirements are to be applied. In its “*Draft Seismic Design Guidelines and Data Submittal Requirements for LNG Facilities*” (FERC Seismic Guidelines), January 2007, FERC Staff gives specific guidance to applicants on its interpretation of the requirements of NFPA 59A (2001), providing consistent design specifications throughout the United States, and a basis for uniform reviews of various LNG terminal sites, structures, components, and systems under FERC jurisdiction.

In general, the FERC Seismic Guidelines are based on existing rules and procedures found in ASCE 7-05, ASCE 4-98, API 650 Appendix E, and other current standards documents applicable to LNG facilities. The guidelines also rely on the National Seismic Hazard Maps and the 2006 International Building Code (2006 IBC) MCE Ground Motion Maps, which were developed specifically for use in the design of buildings and other structures in the United States by the USGS.

The FERC Seismic Guidelines classifies the structures, components and systems identified in NFPA 59A (2001) 4.1.3. - ((1), (2), and (3) above), as “Seismic Category I.” The remaining structures, systems and components are classified as either Seismic Category II or III.

Seismic Category II and III structures, systems and components are to be designed in accordance with the seismic design requirements of ASCE 7-05 (i.e., 2006 IBC). Category II structures, systems, and components must meet the seismic performance goals for “essential” facilities. Category II facilities are expected to survive the Design Earthquake (DE), which is two-thirds the MCE, with potential structural damage that would not be so severe as to preclude continued occupancy and function of the facility. An “Importance Factor” (“I” or “I_p”) of 1.5 is specified for design of Category II facilities.

Category III facilities are considered “non-essential.” Normal, non-essential facilities would be designed for the DE in accordance with ASCE 7-05, and are expected to sustain repairable damage when

subjected to DE ground motions, although it may not be economical to do so. An I_p of 1.0 is specified for design of Category III facilities.

The FERC Seismic Guidelines also provide guidance in determining the appropriate Site Class spectral amplification values and long-period spectra displacement cutoff transition period per ASCE 7-05, inelastic reduction factors for the SSE, minimum safety factors for tank foundation loading and settlement, minimum freeboard requirements for LNG sloshing heights, and selection and location of seismic recording devices.

Geotechnical Site Characterization

The surficial materials are primarily poorly graded dredged sands. Subsurface conditions generally consist of softer compressible soils that represent the larger historic log pond areas and surficial fills used in past site development. These soft soils mantle an upper alluvial sand unit consisting of relatively uniform, medium to fine grained, poorly graded sand ranging in depth up to 86 feet below the ground surface (bgs). This upper sand unit is in turn underlain by up to 59 feet of soft, compressible estuarine silts and clays (from approximately 85 to 135 feet bgs). This zone of silts and clays is in turn underlain by a lower (across the majority of the site) sand unit consisting of medium dense to dense sands. These materials are underlain by the weathered surface of the Columbia River Basalt bedrock at depths ranging from 113 to 181 feet across the site.

The site liquefaction potential was evaluated by URS and they determined that without soil improvement, the upper 75 to 85 feet of the loose to medium dense granular material materials below the water table would liquefy with estimated post-earthquake settlements on the order of 1 to 2 feet for the OBE and SSE events, respectively.

The measured shear velocity, V_s , of the soils profile varies non-uniformly between 220 feet per second (ft/s) at the surface to 740 ft/s at depth of 180 feet. Below a depth of 180 feet, basalt bedrock is encountered, which has a shear wave velocity that is greater than 2,500 ft/s. The average shear wave velocity in the upper 100 feet of the soil profile is about 500 ft/s. This shear wave velocity along with the observation that a significant portion of the overlying soil is susceptible to liquefaction potential characterizes the soil profile as Site Class F in accordance with the provisions of the 2006 IBC (and, by definition, 2007 Oregon State Structural Specialty Code) and ASCE 7-05.

Controlling Seismic Events

Based on deaggregation of seismic sources from the URS Probabilistic Seismic Hazard Analysis (PSHA), for earthquake return periods greater than 200 years, the controlling seismic source is the CSZ megathrust earthquake. The CSZ extends along the coasts of northern California, Oregon, Washington and southern Canada. Since the OBE, SSE, and the MCE all have return periods considerably greater than 200 years, earthquakes on the CSZ are the controlling seismic events for input design motions. The URS PSHA considered three different scenario events for the CSZ megathrust earthquake corresponding rupture distances of 63 km, 46 km and 37 km, respectively from the site. The URS PSHA has also considered three different maximum moment magnitudes (**M**), for the CSZ megathrust, of 8.5, 9.0 and 9.2 respectively, with the **M** 9.0 given the highest weighting.

Input Ground Motions

Input ground motions for the terminal site (also called Design Ground Motions) were determined based on site-specific seismic hazard analysis prepared for the project by URS. The input ground motions were developed prior to the publication of the FERC Seismic Design Guidelines and the adoption of the

2007 Oregon Structural Safety Specialty Code (2006 IBC). Conditions are provided as part of this EIS that will assure that both the FERC Seismic Guidelines (and consequently, the 2007 Oregon Structural Safety Specialty Code) are satisfied. The input ground motions for the project recommended by URS are as follows:

- The URS site-specific MCE ground motion parameters (not adjusted for site effects) are $S_s = 0.80g$ and $S_1 = 0.42g$. The site specific MCE ground motion parameters based on site response analysis are $S_{MS} = 0.817g$ and $S_{M1} = 0.611g$. The site-specific MCE peak horizontal ground acceleration (not adjusted for site effects) is $0.36g$. The site-specific horizontal ground acceleration MCE adjusted for site effects is $0.33g$.
- The site-specific DE ground motion parameters adjusted for site effects (which are two-thirds of the MCE value adjusted for site effects) are $S_{DS} = 0.54g$ and $S_{D1} = 0.41g$. The site specific DE peak horizontal ground acceleration is $0.22g$.
- The OBE was taken as the earthquake ground motion having a ground motion probability of exceedance of 10 percent in 50 years (Return Period = 475 years) at the Cascadia River Basalt bedrock level. Soil structure interaction analysis will be performed during detailed design to determine the OBE response of structures and foundations at the ground surface. The OBE design ground motion response spectra for the site at the Cascadia River Basalt bedrock level has a peak horizontal ground acceleration (i.e., zero period acceleration) of $0.20g$. The vertical OBE design ground spectra (taken as two-thirds of the horizontal spectra for the site at the Cascadia River Basalt bedrock level has peak vertical ground acceleration for the site of $0.13g$.
- The SSE was taken by URS as equal to twice as great as the OBE in accordance with NFPA59A-2001. The SSE design ground motion response spectra, therefore, has a SSE peak horizontal ground acceleration at the Cascadia River Basalt bedrock level of $0.40g$. The vertical SSE design ground motion has a peak vertical ground acceleration for the site at the Cascadia River Basalt bedrock level of $0.27g$.

Proposed Site Improvements

The LNG tanks would be supported on deep pile foundations. No site improvements are planned for under the LNG tanks. Other Category I and II structures would either be supported on deep pile foundations or would have an improved subgrade condition. The site improved subgrade condition would be a combination of removal, replacement, and compaction of the weak surface layer in combination with either vibroflotation or stone columns. The area of improvement would extend at least 10 feet beyond the edge of the foundations. Final design decisions for foundation improvements would be done during detailed engineering.

Category III structures are proposed to be supported on mat foundations. Subgrade improvement design decisions including removal, replacement, and compaction of the weak surface layer would be done during detailed engineering.

In addition, the project intends to construct a 60-feet-wide by 1,500-feet-long by 85-feet-deep vibroflotation improved zone along the terminal river bank to stabilize the site area and to prevent significant lateral spreading. The width of this zone is a preliminary estimate and the actual width would be determined during final design.

Conditions are recommended as part of this EIS that would assure that final site improvement designs would satisfy the FERC Seismic Guidelines. Therefore, the 2007 Oregon Structural Safety Specialty Code would also be satisfied.

Proposed Foundation Design

The LNG tanks would be supported on deep pile foundations. The piles would either be driven steel pipe piles, augercast piles or driven grout piles. The selection and depths of the piles would be determined following a pile test program. While not stated in the URS reports, it is expected the pile depths would be between 120 to 180 feet below the ground surface. Downdrag loads would be considered in the deep pile design.

Other Category I and II structures would either be supported on deep pile foundations or would have an improved subgrade condition. Category III structures are proposed to be supported on mat foundations founded on an improved subgrade condition.

Conditions are recommended as part of this EIS that would assure that final foundation designs would satisfy the FERC Seismic Guidelines. Therefore, the 2007 Oregon Structural Safety Specialty Code would also be satisfied.

Board of Consultants

Given the high seismic risk associated with proximity of the proposed LNG site to the CSZ, the high seismic loads and performance criteria that the facility must accommodate in the event of an SSE, the special design measures required to mitigate the liquefaction potential and potential for lateral spreading, and the need to ensure that all the critical safety-related structures, systems, and components of the facility are properly designed, seismically qualified, and implemented as anticipated, it is essential that all of the required civil and structural design measures be assessed by a qualified independent entity. Therefore, **we recommend that:**

- **Prior to construction of the LNG terminal and pipeline, NorthernStar should retain a “Board of Consultants” (Board) composed of three or more qualified independent engineering consultants experienced in the critical disciplines of geotechnical, civil, structural, and mechanical engineering, to review the final design and to perform construction quality inspections of the civil and structural aspects of the project in accordance with the specifications contained in the FERC’s Draft Seismic Design Guidelines and Data Submittal Requirements for LNG Facilities (FERC Seismic Guidelines) and other measures agreed to by NorthernStar. NorthernStar should file with the Secretary the names and qualifications of the Board members for approval by the Director of OEP.**

The Board should certify that all civil and structural detailed design calculations, analyses, and construction documents are in compliance with all applicable codes and standards, project-specific civil, structural, and mechanical design criteria, and other engineering requirements of the Order, including the FERC Seismic Guidelines. The Board should further certify, based on construction inspections by the Board that all civil and structural construction of the terminal facilities is in conformance with the project construction documents. The Board should also certify that all procured equipment has been properly seismic qualified in conformance with the project-specific seismic qualification requirements, and the FERC Seismic Guidelines, that seismic detailing of structures has been properly

implemented, and the pipeline has been designed to minimize the hazard of rupture due to ground instability. Among other things, the Board should assess the adequacy of the following:

- final geotechnical investigations necessary to support all final foundation designs in satisfying the FERC Seismic Guidelines, and final pipeline routing/mitigation measures through geologically hazardous areas;
- field tests and associated results used to verify ground improvement, pile driving, and all civil and structural construction;
- selection and implementation of the final seismic design categorization of all structures, systems, and components of the LNG terminal in satisfying the FERC Seismic Guidelines;
- proposed seismic recording instrumentation and shutdown alarms in satisfying the FERC Seismic Guidelines;
- construction procedures and progress; and
- continuous and/or periodic inspections made by the Board to ensure that the construction quality of all Seismic Category I, II, and III structures, systems, and components is acceptable.

The Board should meet as necessary to allow the timely progress of the final design approvals and construction of the project in accordance with NorthernStar's production of acceptable interim and final design data. Before each meeting, NorthernStar should file the following material with the Commission and furnish copies to members of the Board, and other appropriate federal and/or state agencies at the request of the Director of OEP:

- a statement of the specific level of review the Board is expected to provide;
- an agenda for the meeting;
- a list of the items to be discussed;
- a discussion of significant events in the design and construction that have occurred since the previous Board meeting;
- drawings of the design and construction features; and
- documentation of the details, calculations, and analyses of the design and construction features to be discussed.

NorthernStar should ensure that the Commission and the Board has sufficient time to review all pertinent materials before each meeting.

Within 30 days of each Board meeting, NorthernStar should file with the Commission copies of the Board's report and a statement of intent to comply with the Board's recommendations or a statement of a plan to resolve the issue(s).

NorthernStar must provide detailed reasons for any recommendation of the Board not implemented.

The Board's review comments should be submitted prior to or simultaneously with NorthernStar's request(s) for approval to proceed with any specific construction-related activities that may be required by the Order. The Director of OEP must approve in writing all requests to proceed with construction.

- **Prior to commissioning of the LNG terminal or commencing service through the pipeline, NorthernStar should file the Board's final report, which should contain a statement indicating the Board's opinion with respect to the construction, safety, and adequacy of the LNG terminal structures and mitigation measures employed along the pipeline route in areas subject to ground instability.**

The design of the facility is currently at the “FEED” (Front-End Engineering Design) level of completion. A feasible design has been proposed but a significant amount of detailed design work still remains to be completed before NorthernStar would be authorized to proceed with any construction activities, if the Commission approves the project. The final engineering design for the LNG terminal would incorporate detailed seismic specifications and other measures to mitigate the impacts of seismic hazards. Information pertaining to the following specific recommendations would be filed with the Secretary for review and approval by the Director of OEP either: prior to commencing final design; prior to construction; or prior to commissioning as indicated by each specific recommendation. All detailed design documents (drawings, calculations, specifications, etc.) and design submittals should satisfy the requirements of Section 4, Part II of the FERC’s draft “Seismic Design Guidelines and Data Submittal Requirements for LNG Facilities,” January 2007 (FERC Seismic Guidelines). In addition to the above-mentioned recommendation regarding construction oversight by an independent Board of Consultants, we recommend that:

- **Seismic specifications to be used in conjunction with the procuring equipment as described in section 3.10 of Part II of the FERC Seismic Guidelines should be submitted for review prior to commencing final design.**
- **Quality Control and Assurance procedures as described in section 3.11 of Part II of the FERC Seismic Guidelines that will be used for design and construction should be submitted for review prior to commencing final design of the project.**
- **A list of Seismic Category assignments for all structures, systems and components should be submitted prior to commencing final design for review as described in section 3.6 of Part II of the FERC Seismic Guidelines.**
- **Seismic Design Criteria should be provided for all Seismic Design Category I, II, and III structures, systems, and components as described in section 3.7 of Part II of the FERC Seismic Guidelines prior to commencing final design. The Seismic Design Criteria should satisfy Part I of the FERC Seismic Guidelines.**
- **LNG Tank (including outer containment tank) and Foundation Preliminary Design should comply with Part I of the FERC Seismic Guidelines. In particular, site response analysis and soil structure interaction analysis should comply with section 6 of Part I and section 3.5.1 (10) and (11) of Part II of the FERC Seismic Guidelines. LNG tank preliminary design drawings and structural calculations as requested in Section 3.9 of Part II of FERC Seismic Guidelines should be submitted for review**

prior to commencing final design. Final LNG Tank (including outer tank) and foundation detailed design drawings and structural calculations that demonstrate compliance with Part I of FERC Seismic Guidelines should be submitted for review **prior to construction.**

- MCE and DE seismic design ground motions should satisfy section 5 of Part I of the FERC Seismic Guidelines. Submittals that demonstrate compliance should be provided **prior to commencing final design.**
- SSE and OBE seismic design ground motions should satisfy section 5 of Part I of the FERC Seismic Guidelines. Submittals that demonstrate compliance should be provided **prior to commencing final design.**
- Details of the liquefaction mitigation method(s), procedures, plan extent, and verification methods proposed to verify mitigation of liquefaction potential should be provided **prior to commencing final design.**
- Detailed calculations of seismic slope stability and lateral movements anticipated after the liquefaction mitigation is implemented should be provided **prior to commencing final design** to verify the stability of critical structures for the project design earthquake motions.
- Details of the types of piles finally selected for supporting the LNG tanks and results of indicator pile program, including load tests, should be submitted for review and approval **prior to construction/pile installation.**
- Final foundation design recommendations including pile foundation design and/or liquefaction mitigation measures for all other structures should be submitted for review and approval **prior to construction.** The foundation design and/or liquefaction measures should satisfy the FERC Seismic Guidelines.
- All other items identified in the submitted geotechnical/seismic reports which were proposed to be addressed during the detailed design should be submitted for review and approval **prior to construction.**
- A seismic instrumentation plan as described in section 3.12 of Part II of the FERC Seismic Guidelines should be provided **prior to commissioning.**
- The results of the hydrostatic load tests on the LNG storage tanks, including settlement data as described in section 7.4.1 should be provided **prior to commissioning.**

Volcanism and Lahars

The Cascade Range contains 13 volcanoes, of which Mount St. Helens, Mount Hood, and Mount Rainier are the closest in proximity to the proposed Bradwood Landing Project. Given their distance from the project facilities, direct impacts are not likely from the eruption of any of these volcanoes, should one occur. However, a secondary phenomenon that is commonly triggered by volcanic eruptions in the Cascade Range is the creation of massive mudflows, known as lahars, which pose a geologic hazard.

While active volcanoes are located within approximately 70 miles of Bradwood, blast zones, lahars, lava flows, or pyroclastic flows would not be likely to reach the proposed LNG terminal site. It is possible that volcanic ash outfall would present minor health hazards. However, due to predominantly westerly winds, ash outfall at the LNG terminal would be unlikely. Particles larger than ash (tephra) could potentially reach the LNG terminal; however, given the distance, the particle size would be relatively small and the chances of such tephra deposition occurring during the lifetime of the project is small. Accordingly, volcanism is not considered a significant geologic hazard that could adversely affect the proposed Bradwood Landing LNG terminal.

Flooding, Tsunamis, Seiches, and Landslide-induced Waves

Flooding, tsunamis, and seiches can cause surface waters to inundate land adjoining them. Tsunamis are caused by large-scale disturbances of the sea floor, typically from subduction zone earthquakes, or large subsea landslides, which can originate thousands of miles away from the tsunami runup area (Priest, 1995a). A seiche is a water wave that occurs in a closed or partially closed body of water, such as a lake or harbor, and is caused by vibratory motion of the ground beneath the water.

The DOGAMI has prepared tsunami hazard maps for the shoreline of the Columbia River up through the Knappa Quadrangle (Priest, 1995b). These maps indicate that tsunami runup elevations would reach approximately 8 feet above msl in the Knappa Quadrangle, and nominal inundation would occur due to a tsunami at a point approximately 4 miles downstream of the proposed Bradwood Landing LNG terminal as a result of a magnitude 8.8 to 8.9 undersea earthquake. The corresponding wave height at the site has been estimated to be less than 1 foot (URS, 2006a). Accordingly, the risk of damage to the proposed Bradwood Landing LNG terminal from a tsunami is considered negligible.

NorthernStar reviewed project-specific and USGS/Puget Sound Consortium Lidar to determine whether existing topography indicates the presence of potential source landslides capable of inducing a wave large enough to inundate the proposed LNG facility following failure into the Columbia River. Generation of a wave large enough to exceed the height of the site perimeter berm (minimum 25 feet NAVD) would require a moderate to large size, fast-moving landslide impacting the river near the terminal with few or no intervening energy dissipaters (islands, river bends, etc.) between the impact site and the facility. The Lidar images indicate local morphology consistent with small-sized, shallow landslides and earthflows. Thus, the likelihood of such small scale slope failures impacting the proposed LNG facility via tsunamis or seiches is believed to be extremely low. However, should one occur, the raised elevation of the site and the earthen berm surrounding the LNG facilities would provide protection against inundation.

Seiches can occur in lakes, rivers and bays, resulting in a larger-than normal wave height. Small seiches have been generated in these types of bounded waters in the Pacific Northwest during distant great magnitude earthquakes (e.g., the 1964 magnitude 9.2 Alaska Earthquake, 1949 magnitude 8.0 Queen Charlotte Islands, Canada Earthquake, and 2002 magnitude 7.9 Denali, Alaska Earthquake). However, no seiche was observed in the Columbia River downstream from the river's dams as a result of these events. Thus, given this history and the fact that the Columbia River is not effectively bounded in the site vicinity, the seiche hazard at the proposed LNG terminal site is negligible.

Federal Emergency Management Agency (FEMA) (1995) insurance rate maps indicate that approximately 70 percent of the Bradwood Landing LNG terminal is susceptible to a 100-year flood event. An additional 10 percent of the site is susceptible to a 500-year flood event. Several feet of dredged fill material has been placed on the site since this FEMA evaluation. NorthernStar proposes to deposit at the terminal up to 400,000 cubic yards of dredge material from the maneuvering area in the Columbia River and raise the final graded elevation of the site to 20 feet NAVD 88, higher than the 100-

year flood level of 13.2 feet. In addition, the LNG storage tanks and related process area would be enclosed by a tertiary earthen berm that would be 5 feet higher. Therefore, the LNG terminal would be protected from adverse effects resulting due to flooding.

URS obtained information from the ODWR on inundation studies performed by the COE for dam failure scenarios (i.e., “Lower Columbia River Inundation Mapping Studies - McNary, John Day, the Dalles and Bonneville Projects,” NPDEN-WM HES September 1982.). The project was carried out in accordance with Hydrologic Engineering Center guidelines for flood emergency planning developed by the COE dated June 1980. The Columbia River stage elevation was compared for a design spillway flood (large peak flow event) versus peak associated and non-peak associated breaches of the dam. The results indicate no effect at CRMs 17.4 and 23.4. At CRM 41.6 there is a 0.1-foot difference in stage elevation between a rainy day design flood plus dam failure event and peak flow from a flood event alone. CRM 41.6 is approximately the location of Wauna on the Oregon side and Cathlamet on the Washington side. Bradwood is between CRMs 41.6 and 23.4 at CRM 38. Therefore, a dam break would not be a threat to Bradwood Landing.

Slope Stability and Load-Bearing Capacity

Finished slopes in the ship berth and maneuvering area at the proposed LNG terminal would be constructed with a 3 (horizontal) to 1 (vertical) ratio for stability. According to the COE (Proudfit, 2008), this is an acceptable slope for sediments in the area of the LNG terminal.

The geotechnical study conducted by URS (2005) indicated that settlement was anticipated within the surficial fills and soft, estuarine sediment layer between 85 and 135 feet below the ground surface at the site, resulting from pseudo-elastic processes, consolidation, and secondary consolidation. Therefore, soil improvements and engineering designs must be implemented to ensure the stability of the LNG tanks, process structures, and equipment associated with the facility. Mitigation measures recommended for the site include ground improvement such as vibroflotation of the liquefiable soils and replacement of the soft surficial soils with compacted engineered fills, and deep foundation support. In addition, the dredged materials proposed to be added to raise the site to the finished design grade would be vibrocompacted to ensure a stable base.

Shoreline Erosion

The shoreline at the proposed LNG terminal site consists of fill materials placed at the site more than 50 years ago and dredged material placed at the site between 1966 and 2002. The riverbank between mean low water and mean high water (MHW) primarily consists of older fill material and construction debris. Some small trees and shrubs have colonized portions of the riverbank. The riverbank appears to be moderately resistant to erosion.

The primary erosive forces affecting the shoreline at the site are produced by high river flows and the wakes of passing ships. During operation of the facility, erosive forces would likely be less than those currently experienced, because LNG carriers moored at the LNG terminal would protect the shoreline from waves generated by passing vessels about one-third of the time. Although the shoreline would be affected by waves generated by the LNG carriers, the ships would be moving very slowly in the vicinity of the LNG terminal and would consequently produce only small waves.

The berthing and unberthing of LNG tankers would be accomplished using tugboats. Conservatively, erosion of the shoreline during this process could be caused by waves generated by the vessels or from the high velocity field created by the tugboats. The potential for bank erosion from ship generated waves was investigated by evaluating the speed required to produce a wave height capable of

removing material from the shoreline, which was conservatively assumed to range between 3 and 6 inches. At present, wind generated waves greater than 6 inches typically occur at the proposed site. The proposed dock would be located about 330 feet away from the shoreline. Based on wave height modeling and the 330-foot distance from the dock to the shoreline, the ship would have to be traveling at 4.65 knots (7.9 feet per second (ft/s)) to generate a wave height of 3 inches at the shoreline from this distance, and 6.1 knots (10.2 ft/s) to generate a wave height of 6 inches at the shoreline from this distance. These speeds are more than twice the expected speed of the ship (less than 2 knots) during the berthing and unberthing processes (West Consultants (WEST), 2006). Thus, waves generated from the vessel would be minimal and the potential for erosion of the shoreline from vessel-generated waves would be low.

The potential for bank erosion from high velocity fields created by tugboats was investigated by evaluating the characteristics of a typical tugboat on the Columbia River. In general, tugboats would be operating within the proposed turning basin with their sterns directed away from the nearshore banks. Assuming the tugboat is operating parallel to the proposed dock, the wake velocities created from a tugboat near the shoreline would be less than 1 ft/s since the dock would be located about 330 feet from the shoreline. Compared to the results of hydrodynamic modeling, this value is significantly less than typical flow velocities along the present shore. This analysis is based on an assumption that berthing operations would occur at MLLW tide levels. However, it is most likely that berthing would occur only at MHW levels. Ship maneuvering operations at MHW conditions would further reduce the estimated tugboat wake velocities.

The maximum surface velocities created from a tugboat pointed directly at the various shoreline areas within the vicinity of the project site were also modeled. The results indicate that the potential for bank erosion due to the high velocity field created by a tugboat would be low for the shoreline along Puget and Tenasillahe Islands, but there is a high potential for bank erosion to occur along the shoreline of the project site under the following conditions:

- the tugboat is located within 1,000 feet of the shoreline;
- the propellers are pointing directly at the shoreline; and
- no object is present between the tugboat and the shoreline.

However, NorthernStar has indicated that it is unlikely these conditions would exist during the berthing and unberthing of a ship because the tugboats would be located along the side of the ship opposite the shoreline of the project site and the large draft of the ship (38 feet) would re-direct the high velocity field created by the tugs towards the invert of the turning basin and away from the shoreline at the terminal site.

Because NorthernStar anticipates erosive forces at the site with the proposed project in place would be no greater and probably less than those currently experienced, no shoreline protection or bank stabilization is proposed. The existing riverbank would be disturbed as little as possible. Some planting would occur between mean low water and MHW and would be extended upward from MHW where circumstances allow. Plantings would consist of low-growing species. Some grading may occur above MHW to facilitate plantings. No wetlands or waters of the United States would be filled along the shoreline, with the exception of the channel connecting the log pond to the Columbia River.

As a condition to the Clatsop County Conditional Use Permit, NorthernStar prepared a *Shoreline Monitoring Plan* for the LNG terminal. The purpose of the monitoring plan is to address the County's concern that dredging of the berth and turning basin could potentially result in changes to the Columbia River hydraulics, which in turn could potentially result in shoreline erosion. The plan identifies criteria for selecting specific monitoring sites, monitoring techniques, and approximate monitoring locations.

The plan also stipulates reporting requirements, which include the monitoring results and proposed measures to reduce erosion of downstream banks should such erosion increase as a result of the project.

Although modeling has indicated that significant shoreline erosion would not occur as a result of LNG carrier wakes and tugboat propeller wash, Puget Island with its residences is particularly sensitive to such impacts. Therefore **we recommend that:**

- **NorthernStar should prepare a Shoreline Monitoring Plan for the west end of Puget Island that is similar in scope to the monitoring plan prepared for the Clatsop County Conditional Use Permit. The plan should be filed with the Secretary for the review and written approval of the Director of OEP prior to operation of the LNG terminal.**

Subsidence

Regional subsidence is typically caused by significant groundwater usage, coal mine collapse, and petroleum mining. However, subsidence through settlement of soils can also occur, and is a potential geologic hazard for the proposed project.

The proposed LNG terminal site is underlain by an estimated 100 feet of normally consolidated sand, silt, and clay alluvium. Upon being subjected to large surface loads, this soil layer is susceptible to land surface subsidence in the form of consolidation of the clayey soils or elastic compression of the sandy soils. Consolidation manifests at the ground surface as settlement and occurs as a function of time proportional to the dissipation of pore water pressures in the normally consolidated clays and silts. Elastic compression occurs nearly instantaneously during loading. The project would not likely result in land surface subsidence and settlement because the large surface loads (i.e., the LNG storage tanks) would be supported by deep foundations that extend below the surficial alluvial deposits and bear into the deeper dense alluvial sands. Mitigation measures such as piling, ground improvements, or specialty foundations may be required depending on the anticipated loads of the structures. The specific mitigation measures to be employed would be developed as the foundation loading requirements of the LNG terminal facilities are developed.

The proposed on-site water well would not withdraw large volumes of water and the existing on-site quarry would be decommissioned and reclaimed in accordance with DOGAMI regulations by filling the below-grade quarry excavations to site grade before operation of the proposed LNG terminal. Therefore, subsidence is not likely to be caused by either of these activities.

Karst

Karst features are created through dissolution of limestone, dolomite, or other rock types from groundwater, creating sink holes, caves, and underground channels that are susceptible to collapse at the surface. The rock types typically associated with karst features are not present in the project area, and no karst conditions are documented at or in the vicinity of the proposed LNG terminal site. Therefore, karst is not a geologic hazard for this project.

Corrosion

Eight soil samples collected from the upper 15 feet at the LNG terminal site were analyzed to assess corrosivity potential for underground utilities and concrete foundations (URS, 2005). The soils were determined to be mildly corrosive to ferrous metals and to have negligible potential to adversely impact concrete. Mitigation measures for corrosion would not be required for the site.

Power Line

Significant geological hazards are unlikely to be present in the vicinity of the proposed electric power line tower sites. Seismic risks to the transmission towers with respect to ground shaking are anticipated to be similar to those present at the LNG terminal site (URS, 2006a). Final tower siting and design before construction would consider geological hazards and would seek to mitigate them through hazard avoidance. In addition, site-specific geotechnical foundation engineering analyses would be conducted as part of the preliminary or final project design.

4.1.3.4 Blasting

Blasting would be necessary during the widening of Clifton Road. Blasting at the existing on-site rock quarry may also be used to generate rock to be crushed for aggregate and sand to produce concrete and foundation bedding. Blasting would be conducted in accordance with all applicable federal, state, and local regulations. These regulations include *State of Oregon 2004 Fire Code Amendments; Explosives, Oregon's Revised Statutes, November 10, 2004*; and the Safe Explosives Act (27 CFR 555) or other more current regulations.

Blasting would not significantly disrupt or impact adjacent properties as no residential properties are located close to areas where blasting may be required. Furthermore, NorthernStar would employ mitigation measures, as necessary, to minimize potential fly rock (i.e., using blasting nets/curtains) and to minimize vibration, noise, and safety impacts (i.e., coordinating with land/property owners in the project area). These mitigation measures would be detailed in a Blasting Management Plan, which NorthernStar would develop prior to beginning construction.

4.1.3.5 Paleontological Resources

We are not aware of any fossil concentrations that would be affected by construction of the Bradwood Landing LNG terminal. Furthermore, available geologic data indicate that fossils have not been observed in the immediate vicinity of the site (Beaulieu, 1973; Steere, 1977; Warren et al., 1945).

4.1.4 Pipeline Facilities

4.1.4.1 Stratigraphy

The proposed Bradwood Landing pipeline would traverse the northern boundary of Oregon's Coast Range physiographic province from the proposed LNG terminal facility at Bradwood, Oregon to the point at which it crosses the Columbia River at Port Westward, Oregon. The pipeline would then extend to the west through the southern portion of Washington's Willapa Hills physiographic province to the pipeline terminus located north of Kelso, Washington. The proposed pipeline route also crosses alluvial lowlands from Wauna, Oregon to Port Westward, Oregon. These lowlands are nearly flat and consist primarily of unconsolidated alluvium from the Columbia River and dredged material.

The stratigraphic units in the area of the pipeline route include those described above in section 4.1.3.1 for the LNG terminal location, as well as the following:

Landslide Debris. Landslide debris is prominent in portions of Clatsop County, Oregon and Cowlitz County, Washington, occurring in areas along the proposed pipeline corridor. The most prominent landslide debris in Clatsop County is located in the vicinity of the community of Wauna between MPs 1.4 and 4.0. This landslide debris has been observed to depths of 156 feet and contains interbeds of alluvium, which suggests repeated movement events in the past (Beaulieu, 1973). The

landslide activity is believed to have occurred during times of lower sea level when the Columbia River was more deeply incised. This geological unit is comprised primarily of randomly oriented weathered mudstone clasts with occasional clasts of basalt and sandstone supported in a mudstone matrix. Hummocky topography, slumps, and slack water ponds are common within these landslide deposits.

Cowlitz Formation. The Cowlitz Formation can be found near the eastern portion of the proposed pipeline route north of Longview. This formation is comprised of upper Eocene thickly-bedded, micaceous, arkosic sandstone with interbeds of siltstone. Localized areas contain cross-bedded, hummocky, or laminated sediments with limited amounts of sub-bituminous coal strata (Walsh, 1987; Newton and Van Atta, 1976).

Steep slopes and thick beds of unconsolidated sediments, comprised of colluvium and alluvium of the Columbia River and its tributaries, form the predominant landforms along the proposed pipeline route. Large basalt cliffs are present southeast of the proposed Bradwood Landing LNG terminal, west of the community of Wauna, west of Abernathy Point, and along Abernathy Creek. The small tributaries of the Columbia and Cowlitz Rivers have carved numerous steep slopes in the tertiary sedimentary and igneous rocks located between Bradwood and Wauna, and between Abernathy Point and the eastern extent of the proposed alignment near Interstate Highway 5. A large Quaternary alluvial plain extends from Wauna to Port Westward. The alluvium consists primarily of unconsolidated silt and fine sand with minor constituents of clay, gravel, cobbles, and boulders.

Table 4.1.4-1 indicates the surface geologic formations crossed by the proposed pipeline by milepost.

TABLE 4.1.4-1			
Geologic Units Crossed by Proposed Pipeline			
MP	Stratigraphic Unit	Age	Lithology
0.0 - 1.4	CRBG	Middle Miocene	Sub-aerial, fine to medium basalt flows layered with Gnat Creek Formation (massive, fine-to coarse-grained, arkosic sandstone and siltstone).
1.4 - 4.0	Wauna Landslide Debris	Quaternary	Ancient landslide deposits of mass wasting processes ranging from surface creep to slump blocks; overlain by Columbia River alluvial deposits.
4.0 – 19.0	Alluvium	Quaternary	Unconsolidated river and estuary deposits of sand, silt, and clay.
19.0 – 19.5	Columbia River	Not applicable	Not applicable
19.5 – 21.6	Grande Ronde Basalt	Middle Miocene	Aphanitic to fine-grained, basaltic andesite flows with associated flow breccia.
19.7 – 23.0	Grande Ronde Basalt, Basalt Gravels and Conglomerates	Middle Miocene	Aphanitic to fine-grained, basaltic andesite flows with associated flow breccia with previously unmapped basalt-clast gravels and conglomerate infilling river channel.
23.0 – 27.0	Grande Ronde Basalt	Middle Miocene	Aphanitic to fine-grained, basaltic andesite flows with associated flow breccia.
27.0 – 31.3	Cowlitz Formation	Upper to Middle Eocene	Massive to thin-bedded, fine to coarse-grained, feldspathic sandstone and carbonaceous siltstone.
31.3 – 32.5	Grande Ronde Basalt	Middle Miocene	Aphanitic to fine-grained, basaltic andesite flows with associated flow breccia.
32.5 – 34.2	Cowlitz Formation	Upper to Middle Eocene	Massive to thin-bedded, fine to coarse-grained, feldspathic sandstone and carbonaceous siltstone.
34.2 – 34.7	Alluvium	Quaternary	Unconsolidated sand, silt, and clay deposited by the Cowlitz River as fluvial and overbank deposits.
34.7 – 36.3	Cowlitz Formation	Upper to Middle Eocene	Massive to thin-bedded, fine to coarse-grained, feldspathic sandstone and carbonaceous siltstone.

4.1.4.2 Mineral Resources

Data on file with the DOGAMI (2005) and WDNr (2005) indicate the only permitted rock quarry within the proposed pipeline right-of-way is the one located at the proposed LNG terminal site. Other mined resources located within 1,500 feet of the pipeline, as identified by USGS topographic maps and discussions with state and federal geologic survey personnel, are listed in table 4.1.4-2.

TABLE 4.1.4-2			
Mines Located within 1,500 feet of the Proposed Bradwood Landing Pipeline			
Facility	MP	Mining Operation	Approximate Distance and Direction from Pipeline
Bradwood Quarry	0.0	Basalt	intersects
Wauna Pit 2	3.2	Basalt	1,500 feet southwest
Weyerhaeuser	24.5	Rock	800 feet south
Westside Quarry	33.5	Rock	1,300 feet north
Fiorito	34.5	Sand and gravel	500 feet north

In addition to the mines listed above, URS (2007b) identified an active basalt quarry located 1,000 to 2,000 feet south of the proposed pipeline route between MPs 32.4 and 33.1. NorthernStar has discussed all mine locations with the corresponding landowners and determined that no hazards associated with past, current, or future mining activities, including subsidence, blasting, slumping, or other ground failure would impact the pipeline. Furthermore, pipeline construction is unlikely to have any significant impacts on current or future mining operations.

Coal mine hazard maps (Culver, 1919; Beikman et al., 1961) indicate that coal deposits exist near Kelso and Castle Rock, Washington. The coal beds are located in the Cowlitz and Toutle Formations and are late Eocene and late Eocene/Oligocene in age, respectively. However, because these coal deposits are limited in extent (Culver, 1919) and are poor in quality (Beikman et al., 1961), we do not anticipate future mining of these coal beds near the proposed pipeline route.

4.1.4.3 Geologic Hazards

Geologic hazards along the proposed pipeline route are described in detail in *Geohazards Report, Proposed Northern Star Natural Gas Pipeline, Bradwood, Oregon to Kelso, Washington*, (URS, 2007a). A second report titled, *Supplemental Geohazards Assessment for Cowlitz County* (URS, 2007b) addresses requirements of the county's Critical Areas Ordinance. These reports are summarized below and are included as part of the public record for the Bradwood Landing Project.³

Resources used to assess the geologic hazards along the pipeline route included published literature, aerial photographs, Light Detection and Ranging (LiDAR) imaging, data from the HDD feasibility assessment (URS, 2006b), and field mapping.

Soil Mass Wasting and Rock Slope Failure

In Oregon, the only portions of the proposed pipeline that would be on or near slopes are within the first 4 miles of the route. The pipeline would be installed using the HDD method between MPs 0.1 and 1.3, thus avoiding potential hazards related to slopes in this area. The Wauna Landslide occurs

³ NorthernStar filed with the FERC its *Geohazards Report for the Proposed Bradwood Landing Pipeline* on March 2, 2007, and filed a *Supplemental Geohazards Assessment for Cowlitz County* on March 22, 2007. These reports are available to the public through the FERC's Internet website at www.ferc.gov. Using the "eLibrary" link, select "General Search," enter the docket number, excluding the last three digits in the field (i.e., CP06-365 and CP06-366), and put in the appropriate date range.

between MPs 1.4 and 4.0. NorthernStar indicated it would install automated vibrating wire strain meters on the pipeline between MPs 1.5 and 4.0 to monitor the landslide debris for movement, which it believes would be the most effective form of mitigation for this landslide area, given its size, age, and lack of recent activity. Maintenance could be performed on the pipeline if strain is detected.

The primary areas for concern relative to slope failure for the proposed pipeline are along the Washington portion of the route (i.e., between MPs 19.6 and 36.3). To evaluate these areas, URS first reviewed landslide data compiled by Cowlitz County for its Critical Areas Ordinance, examined stereo aerial photographs, and then obtained high density LiDAR coverage of a 2-mile-wide corridor centered over the pipeline. The advantage of LiDAR is that it provides a highly detailed digital image of surface topography without the forest canopy. The LiDAR data was also used to run the WDNR Slope Morphology Model, which delineates areas that may be susceptible to slope failure.

NorthernStar identified 110 potential landslide areas in table 4-1 of NorthernStar's Geohazards Report, and ranked each feature by the confidence level that it may be a significant area of unstable slopes. The proposed pipeline would cross 31 potential landslide areas; however, some of these are considered lower confidence features that may require no mitigation following field confirmation. The remaining areas would require mitigation, which may include: relocation of the pipeline route; HDD crossing of the feature to place the pipeline below potential failure surfaces; and instrumentation of the pipe and/or the surrounding rock or soil to monitor strain in the pipe and movement of the surrounding ground. Table 4.1.4-3 summarizes the potential landslide areas crossed by the proposed pipeline route along with preliminary mitigation recommendations. Before final design and construction of the pipeline, additional field mapping and subsurface investigations would be necessary to refine these results and provide data for a final pipeline design geotechnical report. Results of the additional geotechnical studies and proposed mitigation measures would be subject to review by the Board of Consultants prior to construction, as previously recommended.

Seismic-Related Hazards

According to the USGS (2006), the nearest active fault to the proposed pipeline facilities would be the Willapa Bay fault zone, located approximately 27 to 40 miles northwest of the beginning of the pipeline route at Bradwood and the Gales Creek fault zone 25 miles and greater to the south (see figure 4.1.3-1). URS (2006a) also reports the Doty fault, located approximately 25 miles to the north (see figure 4.1.3-1). Other active faults include the Nehalem Bank fault and the Cascadia fold and thrust belt to the west. URS (2006a) reviewed aerial photographs from 1948, 1957, 1966, 1983, and 2001 for indications of possible surface faults in the vicinity of the proposed pipeline route but did not observe any such features.

The pipeline would cross four bedrock faults in Cowlitz County between MPs 22.3 and 24.6; however, these faults are not thought to be active (URS, 2007a). As mapped, these faults are not large enough to produce earthquakes of surface rupture offsets greater than several inches to a few feet. If these faults, or additionally identified faults are found to be potentially active based on future field investigation, the pipeline can be designed to accommodate these small to moderate differential movements across the faults using such mitigation methods as: 1) deformable trench backfill; 2) large diameter, sacrificial carrier pipe; and 3) altering the angle of the pipeline/fault intersection to minimize compressional forces acting on the pipeline.

TABLE 4.1.4-3

Potential Landslide Areas Crossed by the Proposed Bradwood Landing Pipeline in Washington			
Landslide No(s).	MPs	Confidence Level ^a	Proposed Mitigation
4	19.8 – 20.1	high	One or more of the following: (1) reroute to the west to stay on ridge; (2) extend the Columbia River HDD crossing by about 0.5 mile to MP 20.3; or (3) install the pipe by the HDD method between MPs 19.8 and 20.3.
12	20.6 – 20.8	low	The landslide is entirely spanned by the HDD crossing for Cameron Creek. Adjust the depth of the HDD borehole if necessary to assure that the landslide is avoided.
13	20.8 – 20.9	high	The landslide is almost entirely spanned by the HDD crossing for Abernathy Creek. Add 0.2 mile to the southwest end and adjust the depth, if necessary.
24, 34, 35	21.3 -22.1	medium – high	Reroute the pipeline between MPs 21.3 and 21.7 to avoid the toe of Landslide 34. Install automated vibrating wire strain meters on the pipeline between MPs 21.5 and 22.1 to monitor the landslides for movement, and maintain the pipeline if strain is detected.
25B	22.2 – 22.4	medium	About half of the landslide is spanned by the HDD crossing for Germany Creek. Extend the Germany Creek HDD borehole approximately 0.15 mile west and adjust the depth, if necessary.
29, 30	22.5 – 22.7	low – medium	Install automated vibrating wire strain meters on the pipeline between MPs 22.5 and 22.6 to monitor the landslides for movement, and maintain the pipeline if strain is detected. Possibly reroute the portion of the pipeline between 22. 6 and 22.7 to avoid Landslide 30.
43	23.4 – 23.9	high	Install automated vibrating wire strain meters on the pipeline between MPs 23.4 and 23.9 to monitor the landslides for movement, and maintain the pipeline if strain is detected; or install using the HDD method.
53, 54, 56, 57	24.6 – 25.3	low – medium	Install automated vibrating wire strain meters on the pipeline between MPs 24.7 and 24.9 to monitor Landslides 53 and 54 for movement, and maintain the pipeline if strain is detected. Reroute the pipeline to the north between MPs 24.9 and 25.6 to minimize exposure to Landslide 56 and avoid Landslide 57. Install automated vibrating wire strain meters on the pipeline along the portion that crosses Landslide 56.
62	26.5 – 26.7	low	If confirmed in field, install automated vibrating wire strain meters on the pipeline along the portion that crosses the landslide.
67	26.9 – 27.5	high	Conduct additional subsurface investigations to determine the depth of the slide mass. Install the pipeline using the HDD method between MPs 26.9 and 27.5.
71	27.5 – 27.7	low	If confirmed in field, install automated vibrating wire strain meters on the pipeline between MPs 27.5 and 27.7.
73, 74	28.0 – 28.3	low – medium	If confirmed in field, install automated vibrating wire strain meters on the pipeline between MPs 28.0 and 28.3 to monitor Landslides 73 and 74 for movement, and maintain the pipeline if strain is detected.
77	28.6 – 28.7	low	If confirmed in field, install automated vibrating wire strain meters on the pipeline between MPs 28.6 and 28.7.
78	28.9 – 29.2	medium – high	The pipeline has been routed to avoid this landslide but crosses a corner of the feature. If the area of concern is confirmed in field, reroute to avoid.
84, 85	29.8 – 30.4	high	Install the pipeline using the HDD method between MPs 29.8 and 30.4.
86	30.7 – 30.8	Low	If confirmed in field, reroute the pipeline or install automated vibrating wire strain meters on the pipeline between MPs 30.7 and 30.8.
89, 91, 104, 104B	32.0 – 33.2	medium – high	One or more of the following: 1) reroute to avoid portions of the more recently active slides; 2) install with the HDD method; and 3) install automated vibrating wire strain meters on the pipeline to monitor the landslides for movement, and maintain the pipeline if strain is detected.
94	33.9 – 34.0	medium	Install automated vibrating wire strain meters on the pipeline to monitor the landslide for movement, and maintain the pipeline if strain is detected.
103	35.3 – 35.6	medium	If confirmed in the field, one or both of the following: 1) install automated vibrating wire strain meters on the pipeline to monitor the landslide for movement, and maintain the pipeline if strain is detected; and 2) extend the HDD borehole for Interstate Highway 5 to span Landslide 103.
99	35.6 – 35.8	medium	Reroute the pipeline between MPs 35.6 and 35.8 to avoid the landslide.

^a A measure of how certain the investigators are that the feature is an actual landslide, based on the quality of the data.

Empirical reviews of historical earthquakes demonstrate that pipelines are not prone to failure due to earthquakes. A 1996 study of earthquake performance data for steel transmission lines and distribution supply lines operated by SoCal over a 61-year period found that post-1945 arc-welded transmission pipelines in good repair have never experienced a break or leak during a southern California earthquake and are the most resistant type of piping, vulnerable only to very large and abrupt ground displacement (e.g., severe landslides), and are generally highly resistant to traveling ground wave effects and moderate amounts of permanent deformation (O'Rourke and Palmer, 1994). Given that the proposed pipeline route does not cross any known active faults, earthquakes and associated seismic risk are not anticipated to have a significant impact on the proposed pipeline.

The potential for liquefaction along the proposed pipeline route was initially evaluated using liquefaction hazard maps for Cowlitz County, Washington (Palmer et al., 2004) and geologic maps for Clatsop and Columbia County in Oregon (Newton and Van Atta, 1976; Walsh, 1987). Based on these sources, soils with liquefaction potential would be crossed by the pipeline between MPs 0.0 and 19.1, 22.4 and 22.6, 27.9 and 28.0, and 34.1 and 35.5; and at MP 36.2. Geotechnical borings for the HDD feasibility assessment (URS, 2006b) confirmed a high potential for liquefaction exists in the sands and silts of the alluvial deposits south of the Columbia River and in the alluvial deposits on both banks of the Cowlitz River. Furthermore, a Cowlitz County map titled, *Seismic Hazards, Cowlitz County, WA*, indicates the proposed pipeline would cross a seismic hazard area between MPs 34.0 and 35.0, which is the Cowlitz River valley. This area is likely delineated as a seismic hazard area based on the potential for liquefaction of soils within the floodplain.

Because of the horizontal displacement involved, lateral spreading associated with liquefaction can be destructive to linear features such as pipelines. In recent history, no accounts of damage to any existing pipelines have been documented in the project area. Along the proposed pipeline route, potential liquefaction-induced lateral spreading would be largely confined to areas adjacent to the banks of rivers and streams, as soil moves toward the waterbody channels (URS, 2007a). URS conducted a lateral spread analysis at several of the proposed HDD waterbody crossings as part of the HDD feasibility assessment (URS, 2006b) and determined that lateral spreading would be greatest along the banks of the Columbia River during maximum probable earthquake shaking. The stresses and strains on the pipeline resulting from such an event would be less than recommended limiting strains using established pipeline design methodology. Therefore, further mitigation would not be required (URS, 2007a).

Buoyancy induced by liquefaction is generally not a concern for pipelines due to their flexibility but would be addressed if required by placing additional confining weights along the pipeline. Likewise, liquefaction-induced settlement would not impose significant stresses on the pipeline.

Volcanism and Lahars

Historic eruptions of Mount St. Helens produced lahars that traveled to the Columbia River, approximately 20 miles upriver from the proposed LNG terminal site, but did not produce appreciable changes in river elevation. Lava flows and pyroclastic flows terminated within 5 miles of the eruption source. During the 1980 eruption of Mount St. Helens, lahars inundated the Toutle and Cowlitz Rivers. The recurrence interval of a similar lahar or lahar related mudflows is estimated to be approximately 100 years. Sediment profiles in the lower Cowlitz River indicate previous lahar related mudflows were nearly 4.3 feet thick with an estimated over-bank flow thickness of 10.5 feet (Scott, 1989), although geologic maps of the pipeline route area do not depict lahar deposits (Phillips, 1987).

The western portion of the planned pipeline alignment, in the vicinity of the Cowlitz River is mapped as flow hazard Zone 3 (Wolfe and Pierson, 1995). Cowlitz County classifies volcanic hazard areas as coincident with the 500-year floodplain of the Cowlitz River. The scenario with the greatest

potential to impact the area of the proposed Bradwood Landing pipeline would be if a lahar inundated Castle Lake, increasing the water level and resulting in a failure of the natural dam at Castle Lake (Wolfe and Pierson, 1995). The pipeline may potentially be exposed to lahar hazards at river crossings of the Columbia and Cowlitz Rivers. At the Cowlitz River location, the pipeline would be installed at a depth sufficient to be unaffected by scour due to lahars. From the Columbia River crossing and beyond, lahars would be primarily depositional in nature. Sediment deposition would not significantly affect pipeline operations.

Ash was also deposited in the area of the proposed Bradwood Landing pipeline route during the 1980 eruption of Mount St. Helens. Ash and tephra deposition is not anticipated to be a significant geologic hazard for the pipeline due to its underground installation. Furthermore, according to Hoblitt et al. (1998), the annual probability of deposition of 0.4 inch or more of ash is 0.01 percent.

Flooding, Tsunamis, and Seiches

Flooding is possible along the proposed pipeline route between MPs 0.0 and 19.1; at MP 21.1; and between MPs 22.4 and 22.6, 27.9 and 28.0, and 34.1 and 35.0. Because the pipeline would be buried at a depth below expected levels of scour, the only potential impact of flooding would be a tendency for the pipeline to float. In these areas, weighting methods would be used, such as coating the pipe with concrete, to overcome buoyancy hazards during periods of flooding.

According to the DOGAMI (Priest, 1995a), the majority of the proposed pipeline would not be located within the tsunami risk zone. Landslide-induced waves have occurred in the vicinity of the proposed pipeline route, such as the poorly documented 1890 event and the 1965 event at Puget Island. Standardized methods for predicting the occurrence and magnitude of landslide-induced tsunamis do not exist. However, portions of the pipeline located immediately adjacent to the Columbia and Cowlitz Rivers at elevations within a few feet of the river elevation are only at a slight risk of being inundated by a landslide-induced tsunami.

Similar to the LNG terminal, the pipeline segment in the area of the proposed LNG terminal would experience an estimated tsunami wave height of less than 1 foot (URS, 2006a). Other areas that are adjacent to the Columbia River are fairly well protected by Puget, Welch, Tenasillahe, and other islands that would disrupt and disperse the energy of a tsunami or seiche. Therefore, tsunamis and seiches represent a low hazard risk to the pipeline.

Slope Stability

Side slopes during trenching for the pipeline would be maintained in accordance with established engineering and Occupational Safety & Health Administration (OSHA) guidelines, with the steepness of slope at a given location based on the soil type. Soil improvement is not necessary for pipelines due to their linear configuration, strength, and ductility.

Shoreline Erosion

Areas along the Columbia and Cowlitz Rivers are continuously modified by depositional and erosional stream processes. Bank erosion can adversely affect the stability of the pipeline and any associated structures. The risk of shoreline erosion varies from low to high long the proposed pipeline route, depending on the pipeline location relative to the intersection streams. See table 4.3.2-5 for an assessment of the erosion potential at waterbody crossings along the proposed pipeline route. Shoreline erosion would be mitigated through the use of the HDD or conventional bore construction method at waterbody crossings and through revegetation of affected areas.

Subsidence

Because there are no significant aquifers beneath the proposed pipeline route and no petroleum production, risk of subsidence caused by these factors appears negligible. NorthernStar reviewed Beikman et al. (1961), Culver (1919), and Landes (1901, 1902), for possible abandoned coal mines and shafts beneath the proposed pipeline route. No coal mines and/or shafts were identified near the proposed alignment, and the risk of subsidence due to the collapse of coal mine workings would be negligible.

Karst

As indicated in section 4.1.3.3, the rock types typically associated with karst features are not present in the project area. No karst conditions are documented in the area crossed by the pipeline route. Therefore, karst is not a geologic hazard for this project.

Corrosion

NorthernStar would follow the DOT Minimum Federal Safety Standards in 49 CFR 192, which include protection of the pipeline from internal, external, and atmospheric corrosion. The use of both an external protective coating and a cathodic protection system has been required on all pipelines installed after July 1971. The interior of the pipe would be periodically monitored for corrosion using internal corrosion probes and/or in-line pigging tools.

Cowlitz County's Critical Areas Ordinance Considerations

Cowlitz County's Critical Areas Ordinance contains development standards for landslide hazard areas and erosion hazard areas. The standards applicable to the Bradwood Landing Project pertain to grading, erosion control, and buffers. NorthernStar would implement measures designed to meet these development standards. For example, all trenched pipeline installation in geologic hazard areas would be conducted during the dry summer season to minimize short-term erosion issues caused by precipitation runoff and wet ground conditions. Clearing and grading would be done so as to disturb the minimum possible corridor width necessary. Disturbance of trees and vegetation would be restricted to the pipeline construction corridor and access routes into the corridor. Vegetation (slash) would be removed from the construction corridor prior to trench excavation and would not be placed as backfill in any of the pipeline trench excavations.

The trench backfill would consist of native excavated materials except where alternative imported backfill materials are specified in the final pipeline geotechnical report. The trench spoils would be segregated to allow topsoil and organic-rich horizons to be placed in the upper portion of the backfill sequence. Vegetative or engineered ground cover would be placed following completion of pipeline installation in all areas disturbed by the construction activities.

Over 14,000 feet of pipeline along the Cowlitz County portion would be installed using HDD methods. This construction technique would allow construction activities to avoid disturbing areas between ordinary high water and bank tops at waterbody crossings, thus minimizing the potential for erosion.

The development standards in Cowlitz County's Critical Areas Ordinance require an undisturbed 50-foot buffer, as measured on the surface, from the top, toe, and along all sides of any existing landslide or erosion hazard, within a critical area. This buffer may be increased or decreased based on the results of a geotechnical assessment. Construction of the proposed pipeline would require disturbance within the 50-foot buffer surrounding several areas of known landslide or erosion hazard areas. Each of these areas

would be identified, and any necessary remediation or special construction provision would be provided in the final pipeline geotechnical report.

The Critical Areas Ordinance defines actions designed to mitigate project-induced impacts, including avoidance, minimization, restoration, and long-term maintenance. The currently proposed HDD installations are intended primarily for crossing wetlands, waterbodies, and infrastructure; but they also serve to avoid or minimize impacts in erosion hazard and landslide areas. NorthernStar would likely use additional or extended HDD installations to avoid some of the other identified landslide hazard areas (see table 4.1.4-3). Where the pipeline is proposed to traverse steep slopes using trenching installation methods, the alignment has been oriented as close to the fall line of the slope as possible to reduce exposure of the pipeline to lateral strain due to slope creep and to shorten the total slope distance that the pipeline would cross.

All construction and access rights-of-way, including in erosion hazard and landslide areas, would be rehabilitated following completion of construction. The permanent pipeline right-of-way would be maintained as a utility easement for the lifetime of the facility. Temporary easement areas would be rehabilitated to a state that matches or improves the preconstruction conditions. The pipeline would be inspected routinely both on the ground along the alignment and on the interior of the pipe, and maintenance would be performed as needed.

4.1.4.4 Blasting

Shallow bedrock may be encountered along several portions of the proposed pipeline route. However, the near-surface rock is generally weathered and highly jointed. Therefore, the pipeline could likely be installed using conventional trenching and ripping methods. NorthernStar does not anticipate blasting would be required. However, if blasting becomes necessary, it would be conducted in the same manner described for the LNG terminal above.

4.1.4.5 Paleontological Resources

William Orr, Ph.D., Curator of the Condon Museum at the University of Oregon indicated it is likely that significant fossils of vertebrates could be found during excavation of the pipeline. Should paleontological resources be encountered during the project, NorthernStar would implement mitigation procedures based on the recommendations of Dr. Orr and other appropriate authorities, including but not limited to field data recovery.

4.2 SOILS AND SEDIMENTS

4.2.1 Waterway for LNG Marine Traffic

4.2.1.1 Soil Resources

Other than the potential for shoreline erosion, which is addressed in section 4.1.2.3, LNG marine traffic would not have a significant impact on soils along the waterway from the territorial seas to the LNG terminal site. Furthermore, a release of LNG from an LNG carrier as a result of an accident or intentional breach would not have an impact on soil resources.

4.2.1.2 Sediments

The existing sediment conditions and impacts of the proposed project on sediments within the waterway at and in the vicinity of the LNG terminal site are discussed in section 4.2.2.2. Because the LNG carriers would be operating within an existing dredged navigation channel along with other ship traffic, LNG marine traffic would not be likely to have a significant impact on sediments within the remainder of the waterway. Furthermore, a release of LNG from an LNG carrier as a result of an accident or intentional breach would not have an impact on sediments because it is not soluble in water and would float on the water surface before vaporizing.

4.2.2 LNG Terminal

4.2.2.1 Soil Resources

Information regarding soils in the proposed LNG terminal area is based on the Soil Survey of Clatsop County, Oregon (U.S. Department of Agriculture - Soil Conservation Survey (USDA-SCS), 1988) and the Soil Survey Geographic Database (SSURGO) (USDA-Natural Resources Conservation Service (NRCS), 2003). Additional information about the soils was obtained from Official Soil Series Descriptions (USDA-NRCS, 2004).

Existing Soil Resources

The proposed LNG terminal would be located in the Northern Pacific Coast Range, Foothills, and Valleys Major Land Resource Area (MLRA). The dominant soils in this MLRA are Umbrepts and Ochrepts. These well drained, gently sloping to very steep soils have a mesic temperature regime and mixed mineralogy.

The proposed LNG terminal would be located within a 411-acre parcel which contains Braun, Harslow, Kilchis, Locoda, Scaponia, and Udipsamment soils. Approximately 70 acres would be disturbed by construction of the LNG terminal and associated elements, including the parking lot and power line. The dominant soil type at the LNG terminal is Udipsamments, covering about 86 percent of the construction work area. Other soils at the terminal include Locoda silt loams, Harslow-Kilchis very gravelly loams, and Scaponia-Braun silt loams. Following construction, about 31.2 acres of Udipsamments, 4.5 acres of Locoda silt loams, and 0.01 acre of Scaponia-Braun silt loams would be encompassed within the footprint of the facility components (e.g., marine facilities, structures, process areas, roads, etc.).

A parking lot would be provided for construction workers southeast of the Taylorville interchange at Highway 30. This location for the construction worker parking lot has been changed from the original location proposed by NorthernStar and no information has been provided about the new site

regarding soils or other resources. In addition, modifications are now being proposed to Bradwood Road and Clifton Road that would disturb areas outside the current footprint. Therefore **we recommend that:**

- **Prior to construction of the LNG terminal, NorthernStar should file with the Secretary the following information regarding the new proposed construction worker parking lot, Bradwood Road, and Clifton Road: map of disturbed area; soils; impacts on upland vegetation, waterbodies and wetlands, and wildlife habitat; occurrence of state- or federally listed species; land use and zoning; cultural resources, and restoration plans. NorthernStar should include status and copies of agency clearances for wetlands, threatened and endangered species, and cultural resources, as applicable.**

Non-jurisdictional facilities associated with the proposed LNG terminal include a 1.5-mile-long power line and three lateral pipelines. As discussed in section 2.2.2, the lateral pipelines would be constructed by entities other than NorthernStar and are tentative at this time. The power line would require a 100-foot-wide right-of-way for construction and operation. Approximately 0.3 mile of the power line would be located with the terminal site discussed above. Soils within the remainder of the power line corridor consist of 8.3 acres of Braun-Scaponia silt loams, 5.8 acres of Scaponia-Braun silt loams, 1.2 acres of Harslow-Kilchis very gravelly loams, and less than 0.1 acre of Udipsamments.

According to the soil survey of Clatsop County, Oregon (USDA-SCS, 1988), the Udipsamments consist of sandy soils that formed in stratified dredged materials along the Columbia River. Udipsamments are very deep, excessively drained soils with slopes ranging from 0 to 15 percent. The Locoda soils are finer textured soils formed in mixed alluvium located on tidally influenced flood plains. These are very deep, very poorly drained soils with slopes ranging from 0 to 3 percent. The Harslow and Kilchis soils consist of very gravelly loams formed in mixed colluvium along mountainsides. These are shallow to moderately deep, well drained soils with slopes ranging from 60 to 90 percent. The Braun and Scaponia soils consist of silt loams formed in colluvium weathered from siltstone. These are moderately deep, well drained soils with slopes ranging from 3 to 60 percent. The Alstony soils consist of gravelly loams formed in colluvium weathered from igneous rock. These are deep, well drained soils with slopes ranging from 30 to 60 percent. The Anunde soils consist of silt loams formed in colluvium weathered for siltstone. These soils are very deep and well drained with slopes ranging from 3 to 30 percent.

Contaminated Soils

In August 2005, AMEC Earth and Environmental, Inc. (AMEC) prepared a revised Phase I Environmental Site Assessment for the proposed terminal site. The Environmental Site Assessment included a review of regulatory databases and a site inspection to identify known contaminated sites on or near the proposed LNG terminal. No contaminated sites were identified within 0.25 mile of the proposed LNG terminal site. However, the Environmental Site Assessment did identify several Recognized Environmental Concerns (REC) on the property, including two gasoline underground storage tanks (UST), an area where a former train/maintenance shop building was located, asbestos containing cement board, solid waste disposal and burn areas, and the potential presence of polychlorinated biphenyls (PCB) and dioxins in dredged sand deposited at the site. The power line corridor was not examined in the Environmental Site Assessment; however, the search radius used for the review of regulatory databases included portions of the proposed power line route. In addition, surveys of the corridor and construction parking area did not identify any features that would constitute RECs.

Based on historical site activities, the potential exists that contaminated soils are present at the LNG terminal site. Improper handling of contaminated materials encountered during construction could spread contaminants to surface and groundwater and other sensitive resources, as well as represent a

health risk to workers. NorthernStar does not anticipate encountering potentially contaminated material during the construction of the terminal. If final design results in the need to advance deep excavations within the footprint of particular RECs, NorthernStar would prepare a *Contaminated Materials Management Plan* (CMMP) that would specify the procedures to identify, characterize, and properly manage potentially contaminated materials. The CMMP would be submitted to the appropriate agencies for approval before construction. To ensure that personnel working on the project are prepared to appropriately handle an unanticipated encounter with contaminated soils, a CMMP should be prepared regardless of whether or not the final design includes deep excavations. Therefore, **we recommend that:**

- **NorthernStar should prepare its CMMP to address the discovery and management of contaminated soils and groundwater. This plan should comply with applicable state and federal regulations and should include procedures for the identification and management of unknown contaminants if any are encountered during construction of the proposed LNG terminal and pipeline facilities. The plan should be filed with the Secretary for the review and written approval of the Director of OEP prior to construction.**

Impacts and Mitigation

Construction activities such as clearing, grading, and the movement of construction equipment over work areas may affect soil resources. Clearing removes protective cover and exposes the soil to the effects of wind, sun, and precipitation, which may increase the potential for soil erosion and the movement of sediments to sensitive areas. Grading and equipment traffic may compact soil, reducing porosity and percolation rates, which would result in increased runoff potential. Contamination from spills or leaks of fuels, lubricants, and coolants from construction equipment could also impact soils.

Operation of the LNG terminal would permanently convert 35.7 acres of soil to a commercial/industrial use. Project-related impacts on soils would be minor. There are no prime farmland soils at the LNG terminal. The majority (98 percent) of the soils within the proposed LNG terminal site are not considered to be highly erodible land (HEL) or potentially highly erodible land (PHEL) and are therefore not susceptible to erosion by water. However, the Udipsamments have a wind erodibility group (WEG) classification of 2 and are considered to be susceptible to wind erosion.

Maintenance of the 100-foot-wide power line corridor would permanently convert approximately 15 acres of soil outside the terminal site to commercial/industrial uses. None of the soils within the corridor that would potentially be affected are considered prime farmland. Less than 1 percent of the soils within the corridor are considered to be susceptible to wind erosion. However, essentially all (greater than 99 percent) of the soils within the power line corridor are considered HEL and susceptible to water erosion.

NorthernStar would mitigate impacts on soils at the proposed terminal and associated work areas by implementing the measures specified in its terminal ESC Plan. NorthernStar's terminal ESC Plan includes measures to control erosion and sedimentation during construction, ensure revegetation to prevent erosion following construction, and prevent and control spills.

4.2.2.2 Sediments

As discussed in sections 2.1.3.1 and 2.4.1.2, the construction and operation of the proposed LNG terminal would require dredging of subsurface sediments in the Columbia River adjacent to the facility to safely navigate vessels from the river channel to the berth at the terminal. Current water depths within the proposed dredge footprint range from -21 to -51 feet CRD. The proposed design depth is -42 foot CRD

with a 1-foot overdredge allowance, for a total project depth of -43 feet CRD. NorthernStar anticipates that up to 700,000 cubic yards of sediment would be dredged to obtain the proposed design depth and overdredge allowance.

In accordance with the Lower Columbia River Management Area Dredged Material Evaluation Framework (DMEF) developed by the Regional Management Team (RMT), an inter-agency task force⁴ that studies dredging on the Columbia River, NorthernStar conducted a Tier I evaluation of the project area. Because the Tier I evaluation indicated the presence of generally low levels of some chemicals of concern, a DMEF Tier IIB analysis (physical and chemical analyses) was selected as the most appropriate level of evaluation for the proposed dredged materials.

Sediment Sampling

Sampling and Analysis Plan

NorthernStar developed a *Sampling and Analysis Plan* (SAP) (AMEC, 2006) that details the sediment collection and testing program conducted on the proposed dredged material. The SAP was developed based on procedures outlined in the Lower Columbia River Management Area DMEF (COE et al., 1998). The sediment sampling and analysis program followed the DMEF Tier IIB approach (physical and chemical analysis) for evaluation of the proposed dredged material. The SAP received conditional approval from the RMT in early February 2006 (AMEC, 2006).

Seven horizontally delineated areas were selected within the proposed dredging footprint to characterize the nearshore and offshore sediments (see figure 4.2.2-1). Areas 1 through 3 were closest to the shoreline, whereas areas 4 through 7 were offshore parallel to the navigation channel. Generally, five core locations were designated within each area in locations with the thickest deposits of proposed dredged materials (dredge prism). The exception was area 7, with only a single core location. Area 7, a small triangular area at the northeast corner of the proposed dredging area, was added before the last SAP revision at the suggestion of the local river pilots. This sample point was intended to provide additional data for an area to be dredged to provide better navigational maneuvering for carriers approaching the turning basin from the main channel.

Dredged Material Management Units (DMMU) were designated based on the DMEF ranking protocol, although different rankings were established for different areas of the dredge prism because sediments are believed to be heterogeneous across the site. Top, middle, and bottom strata DMMUs were designated for each horizontal area, where sediments were sufficiently thick. For all areas, the top 4 feet was considered the top stratum, the core segment from 4 to 10 feet was considered the middle stratum, and material below 10 feet to the project depth (including overdredge) was designated the bottom stratum. The leave surface horizon (1 foot below the maximum overdredge depth—termed the “Z” stratum) was also to be sampled. Sediments from the top, middle, and bottom DMMUs were to be composited by sample area yielding a total of 18 sediment samples for analysis from the proposed dredge prism. Samples from the leave surface were not to be composited. Two additional samples from designated reference cores were also to be analyzed.

⁴ Included in the RMT are representatives of the COE, EPA, ODEQ, WDE, and WDNR.

 Partial Target Depth

February 2006 Sampling Event

Between February 9 and February 26, 2006, vibracore samples were collected at all 33 locations specified in the revised SAP, including 31 cores in the dredge prism and 2 reference site cores. Sample processing was conducted onboard an SWCA Environmental Consultants (SWCA) research vessel moored alongside the sampling vessel. Collected samples were stored in iced coolers, or kept in a secured refrigeration unit at 39.2 °F. Methods and materials used for each physical and chemical analysis performed at the lab are detailed in *Sediment Characterization Report*, dated May 24, 2006 (SWCA, 2006). Deviations from the SAP are described below.

Core sediments collected for DMMU composite samples were not mixed together in the field using a drill operated stainless steel impeller as specified in the SAP. Under field conditions, the use of an electric drill was determined to pose an unacceptable potential for external contamination as a result of wear from the drill's copper bushings. Mixing of the composite samples was conducted in the analytical laboratory, where controlled conditions minimized the potential for contamination. Equal amounts of material from specific strata within the DMMU were stored in a sealed composite sample jar with instructions for the laboratory staff to mix well before running analyses. NorthernStar does not believe the analytical results were affected by this deviation from the SAP.

Full penetration to target depth was achieved at 19 core locations. Partial cores were collected at 12 locations (see figure 4.2.2-1). The vibracore sampler was not able to penetrate the substrate to the target depth specified in the SAP at these 12 sites. Refusal was declared if core advancement stopped at the same depth on subsequent attempts, repeatedly showed similar obstructing bottom material, and/or equipment showed damage from attempting to core into impenetrable materials. Apparent reasons for these refusals included dense gravel layers, wood, and densely packed sands (SWCA, 2006). An acoustic survey conducted in June 2005 found a distinct sub-bottom layer of "consolidated sediments." This consolidated layer slopes upwards in the northwestern portion of the dredge area, where most of the partial core penetrations occurred.

Partial refusals resulted in a change in the compositing scheme for some bottom (B) DMMU composites (see table 4.2.2-1). As a result, the number of constituent core locations for a composite was reduced if one or more cores within a sampling area was not attained due to refusal. In DMMU 2, for example, only core locations 2A and 2B were targeted constituents of the bottom composite. However, at core location 2B the bottom stratum was not obtained and thus, the "composite" consists only of material from core location 2A. Similarly, in area 4 the targeted B strata was not attained at core locations 4A, 4B, 4D, and 4E, leaving only core 4C to fill the DMMU composite for the B strata. All B strata constituents were obtained for the targeted DMMU composites from sites 3, 5, and 6. Top (T) and middle (M) DMUU strata were collected at all core locations in keeping with the SAP. Samples from the "leave surface" collected during this sampling event were placed in archival storage at the analytical laboratory pending agency responses to the submitted results.

NorthernStar indicated that tributyl tin analysis of pore water was not feasible because the highly sandy nature of the sediment resulted in very limited pore water recovery. As discussed in the SAP, bulk sediment analysis for tributyl tin was performed on DMMU composite samples.

May 2006 Sampling Event

On May 24-25, 2006, a truck-mounted rotary mud drill rig was deployed from a barge to obtain samples at 7 of the 12 sites where partial refusal during the original sampling effort prevented sampling of the bottom and/or leave surface. These sampling sites were chosen in consultation with NMFS (SWCA, 2007). All 12 samples from these 7 cores were placed in archival storage at the analytical laboratory pending analysis instructions.

February 2007 Sampling Event

In a letter dated June 30, 2006 NMFS staff requested retene analysis for the 10 DMMUs in areas 4 through 7, full analysis of May 2006 samples, and full analysis of individual leave surface samples. In a memorandum dated October 3, 2006, NMFS staff reiterated their previous request and further specified mercury, VOCs, and DMEF Tier IIA analysis be performed. When NorthernStar requested additional laboratory analysis of the May 2006 samples placed on hold at the analytical laboratory, it learned that the samples had been inadvertently discarded by laboratory staff. Therefore, on February 6-7, 2007, replacement samples were collected by mud rotary drilling techniques at the same seven core locations.

Sampling generally followed the SAP except as described for the February 2006 sampling event relative to composite sample mixing and number of fractions. Because of poor sample recovery, composite samples 1B and 2B each consisted of only one fraction rather than the four and two fractions, respectively, specified in the SAP. Composite sample 4B consisted of three fractions compared to the five intended in the SAP. Additionally the sampling deviated from the SAP in that the sampling depth for bottom and leave surface strata were modified to reflect new potential maximum dredging depths. Bottom strata were extended downward 2 feet and Z strata were shifted 2 feet lower than specified in the SAP.

Physical and Chemical Analyses

Grain size analysis was performed on 18 DMMU composite samples and 2 reference samples following agency approved methods. The sediment sampled from the proposed dredge prism contained very small quantities of fines. Fines are sediments that are smaller than 0.65 mm, equivalent to material that passes through a standard series 230 sieve. Fines are important due to the tendency of contaminants to adhere to fine grained particles. Composite cores from each DMMU contained over 93 percent

material retained on a 230 sieve, and 15 of the 18 samples contained over 97 percent material retained on a 230 sieve. The results of the grain size analyses indicated that the sediments in the proposed dredging area generally consist of sands.

Sediment samples were chemically analyzed according to agency approved methods for the constituents listed in the DMEF. Additional analyses included guaiacols, resins, and phytosterols. These analytes were included due to concerns expressed by NMFS staff resulting from the site's former use as a lumber mill.

Details of the chemical analyses are available in SWCA (2006, 2007). The results of the chemical analyses presented below are summary discussions by contaminant class. The laboratory results summarized below are reported to method reporting limits (MRL). A not detected result for a given compound was defined by the laboratory as "analyzed for, but not detected at or above the MRL."

The NOAA Squirt (Screening Quick Reference Tables) tables provide a listing of chemical concentrations for inorganic and organic contaminants in various environmental media. The tables can be used to initially identify substances that may threaten aquatic resources of concern to NOAA. The results of chemical tests conducted for proposed projects may be compared to values listed in the Squirt tables to provide initial screening for potential contaminants of concern. The tables are intended for preliminary screening purposes only, and do not represent criteria or clean-up levels.

Total Organic Carbon

In the dredge prism samples, total organic carbon (TOC) ranged from not detected (in eight DMMUs) to 0.78 percent at DMMU 1M. TOC in the leave surface samples ranged from 0.14 to 1.79 percent. Reference sites ranged from not detected to 0.05 percent. These values are consistent with the highly sandy nature of the sediments.

Total Volatile Solids

Total volatile solids in the dredge prism ranged from 0.56 percent in DMMU 5T to 1.61 percent in DMMU 6T and the reference sites had 0.7 and 0.8 percent total volatile solids. Total volatile solids in the leave surface samples ranged from 0.67 to 2.11 percent. As with TOC, the percentage of volatile solids is consistent with the highly sandy nature of the proposed dredged sediments.

Metals

The sediment samples were analyzed for 10 heavy metals. The results are summarized in table 4.2.2-2 along with several screening, threshold effects, and background levels for comparison.

Arsenic, chromium, copper, lead, nickel, and zinc were detected in all samples. Mercury and selenium were each detected in only one dredge prism sample and no leave surface samples. The concentrations detected were all below the Lower Columbia River Management Area DMEF screening levels, the draft Sediment Evaluation Framework (SEF) SL1 levels, and the lowest NOAA Squirt table Threshold Effects Level (TEL). The concentrations were also either below or very near the highest NOAA Squirt table "background" levels. Some of the chromium concentrations in both dredge prism samples and leave surface samples exceeded typical background levels near the site in the Columbia River, but the concentrations of all other metals were less than or within the range of nearby background levels.

TABLE 4.2.2-2

Summary of Results for Heavy Metals in Sediments

ND	Not Detected								

Butyl tins are organometallic compounds associated with marine vessel maintenance and construction activities or sources. Tributyl tin was not detected in any of the dredged prism samples or the reference samples but was detected in four leave surface samples at concentrations ranging from 1.6 parts per million (ppm) to 5.4 ppm. These concentrations are below the draft SEF SL1 (dry weight) level of 75 ppm.

Organic Compounds

NorthernStar analyzed the proposed dredge sediments for a suite of standard volatile and semi-volatile organic compounds. None of the eight volatile organics analyzed for were identified at or above the MRL in the samples from the dredge prism, leave surface, or the reference sites. Of the 39 semi-volatile organic compounds for which the samples were analyzed, only 4 polycyclic aromatic hydrocarbons (PAH) and 2 phthalates were detected above the MRLs. During the February 2006 sampling event, the PAHs fluoranthene and pyrene were identified at 13 and 15 parts per billion (ppb), respectively, in one DMMU (3M); and acenaphthene, phenanthrene, and pyrene were detected at similar concentrations in one leave surface sample (3DZ). The concentrations of these compounds were at one to two orders of magnitude below their respective DMEF screening levels and SEF SL1s. The concentrations were also below the applicable lowest NOAA Squirt table TELs. These PAHs are recognized byproducts of petroleum combustion and the low levels identified in isolated samples may represent contamination from sampling vessel diesel exhaust.

Bis(2-ethylhexyl)phthalate was detected in leave surface sample 4BZ at a concentration of 110 ppb, which compares to the DMEF screening level of 8,300 ppb and the SEF SL1 level of 220 ppb. Diethyl phthalate was detected only in the Reference Site 2 sample. The concentration of 18 ppb was

below the DMEF screening level of 1,200 ppb. No NOAA Squirt table guidelines or other SEF screening levels have been established for these compounds.

Pesticides

None of the 21 pesticides analyzed for were identified at or above their respective MRLs in samples from the proposed dredged materials or the reference site samples. Methoxychlor was detected in leave surface samples 3BZ (1.1 ppb) and 7AZ (8.0 ppb). Neither sediment screening levels nor TELs are established for this pesticide in current versions of the DMEF, SEF, or NOAA Squirt tables.

Polychlorinated Biphenyls

NorthernStar analyzed the sediments for seven individual PCBs. None of the PCBs were detected at or above the MRL in any of the samples.

Dioxin and Furans

Samples from each DMMU and the reference sites were analyzed for 7 dioxins and 10 furans. In addition, samples were analyzed for total tetra-dioxins, penta-dioxins, hexa-dioxins, hepta-dioxins, tetra-furans, penta-furans, hexa-furans, and hepta-furans. Results for the parameters that were detected above the MRL in at least one sample are summarized in table 4.2.2-3.

TABLE 4.2.2-3

^a	NOAA Squirt table Upper Effects Threshold (UET) for 2,3,7,8-TCDD.				
^b	World Health Organization toxic equivalency factor totals.				

Totals for 2,3,7,8-TCDD equivalents, calculated using World Health Organization toxic equivalency factors, ranged from zero to 0.173 parts per trillion. These 2,3,7,8-TCDD equivalent totals are well below the NOAA Squirt table upper effects threshold (UET) for 2,3,7,8-TCDD of 8.8 parts per trillion.

Sulfide and Ammonia

Total sulfide was detected at only one DMMU (1AM at 0.7 percent); it was not detected in the reference samples. None of the leave surface samples were analyzed for total sulfide. Ammonia as nitrogen ranged from 0.5 to 17.2 ppm in the dredge prism samples and from 8.0 to 18.0 ppm in the leave surface samples. Reference sample results for ammonia were 7.9 and 3.3 ppm at sites 1 and 2, respectively.

Guaiacols and Resins

Analysis for guaiacols, retene, and resin acids was requested by the NMFS due to concerns related to the site's history as a lumber mill. The following compounds were tested for, but not detected at or above the MRL in any of the dredge prism or leave surface samples: pimaric acid; 3,4,5-trichloroguaiacol; tetrachloroguaiacol; 9,10-dichlorostearic acid; 12-chlorodehydroabietic acid; 14-chlorodehydroabietic acid; and dichlorodehydroabietic acid. The reference site samples were not analyzed for these compounds. Table 4.2.2-4 summarizes the results for the remaining compounds.

TABLE 4.2.2-4		
Summary of Results for Guaiacols, Retene, and Resin Acids in Sediments		
Compound	Dredge Prism	Leave Surface

Abietic Acid	ND – 0.041	ND – 0.057
Notes:	All concentrations in ppm. Results for dredge prism and leave surface samples reflect the range of concentrations measured in the samples.	
NA	Not Analyzed	

Neither sediment screening levels nor TELs are established for these compounds in current versions of the DMEF, SEF, or NOAA Squirt tables. However, in a memo to the Commission dated June 30, 2006, NMFS staff indicated that the agency has used an estimated sediment toxicity benchmark for retene of 1.1 milligrams of retene per gram of TOC (mg/g). Using this benchmark, TOC-adjusted retene concentrations in the four dredge prism samples where the compound was identified and TOC was analyzed are 0.012 mg/g, 0.018 mg/g, 0.38 mg/g, and 0.61 mg/g. TOC data was available for only two of the five leave surface samples in which retene was detected: in sample 2AZ, which also had the highest retene concentration, and in sample 1BZ. The TOC-adjusted retene concentrations in these samples are 0.58 mg/g and 0.084 (mg/g), respectively.

Phytosterols

Phytosterols, also known as plant sterols, are a naturally occurring class of compounds found in the cells and membranes of plants. There are approximately 250 different sterols and related compounds

in plant and marine materials with the most common ones being beta-sitosterol, stigmasterol, and campesterol (Forbes Medi-Tech, 2006). In fish, they may have reproductive effects and could be responsible for some types of reproductive dysfunction observed in fish exposed to pulp mill effluents (Tana et al., 1994 as cited in NMFS, 2004a). Sediment concentrations of phytosterols vary widely. Phytosterol concentrations in sediments from sites that are not specifically associated with pulp mills range from less than 1 to approximately 30 micrograms per gram ($\mu\text{g/g}$) dry weight (Hasset and Lee, 1977; Mudge et al., 1999 as cited in NMFS, 2004a). Data regarding phytosterol concentrations in sediments associated with pulp mills are limited. Leeming and Nichols (1998) reported total sterol concentrations from the Upper Derwent Estuary in Tasmania in the 30-110 $\mu\text{g/g}$ dry weight range in sediments that were closest to pulp mill discharges, and from 0.6 to 8.1 $\mu\text{g/g}$ dry weight at sites farther from mill sites (NMFS, 2004a). Phytosterols were analyzed in the proposed dredge sediments for the Bradwood Landing Project because of the site's history as a former lumber mill.

Dredge prism and leave surface samples were analyzed for four phytosterols and each was detected in at least several samples. The results are summarized in table 4.2.2-5. As might be expected, phytosterol concentrations were highest in both DMMU and leave surface samples nearest shore. Beta-sitosterol was the most commonly identified compound, occurring in 19 of the 26 leave surface samples and 13 of the 15 DMMU samples collected in 2007. Stigmastanol was identified in about 30 percent of the DMMU and leave surface samples. Campesterol was found in 19 percent of the leave surface samples and 13 percent of the DMMUs. Stigmasterol was identified in only two samples from the leave surface. Phytosterol contents of the sediments in the proposed dredging footprint were within the range of concentrations reported for sediments not specifically associated with paper or pulp mills cited above.

TABLE 4.2.2-5		
Summary of Results for Phytosterols in Sediments		
Compound	Dredge Prism	Leave Surface
Stigmastanol	ND – 0.44	ND – 2.3
Campesterol	ND – 0.33	ND – 0.87
Beta-Sitosterol	ND – 4.1	ND – 15.0
Stigmasterol	ND – 3.30	ND – 0.29
Notes: All concentrations in ppm ($\mu\text{g/g}$). Results for dredge prism and leave surface samples reflect the range of concentrations measured in the samples.		

There are neither sediment screening levels nor TELs for these compounds in current versions of the DMEF, SEF, or NOAA Squirt tables. Because these compounds are not routinely tested for in Columbia River sediments, a database of background levels has not been established to which these concentrations can be compared.

Phytosterols are relatively insoluble in water. In laboratory studies assessing the effects of phytosterols on fish, these compounds were dissolved in ethanol or acetone before being added to the test waters (Lehtinen et al., 1999; Tremblay and Van Der Kraak, 1999). The mean TOC content in sediments from the DMMU samples was 0.25 percent (SWCA, 2006). The mean TOC content from the leave surface samples was 0.47 percent. The relatively low TOC content of the sediments within the dredge prism suggests a limited potential to mobilize phytosterols from the sediments during dredging or from the leave surface during operation of the facility.

Summary of Physical and Chemical Analysis of Sediments

Results for the physical and chemical analysis of the sediment from the proposed dredge prism and the two reference sites are summarized below.

- All sediment samples in the proposed dredge area consisted of at least 90.4 percent sand or gravel, and contained less than 1.8 percent TOC and less than 2.2 percent total volatile solids.
- Metals results were all well below DMEF, SEF, and NOAA Squirt screening and TELs, and were generally within background levels. The concentrations were generally evenly dispersed horizontally and vertically throughout the dredge prism.
- No VOCs or PCBs were detected.
- The only semi-volatile organic compounds detected were several PAHs, which were detected in two samples. The detected concentrations of these compounds were relatively low compared to applicable screening and TELs. The presence of the PAHs in the samples may be the result of accidental contamination during sampling by vessel diesel exhaust.
- Toxicity equivalency factor totals for dioxins and furans were well below the NOAA Squirt table UET level of 8.8 parts per trillion.
- Analytical results for guaiacols, resin acids, and phytosterols were variable across the samples with positive correlations observed between the concentrations and the presence of woody debris in the core samples. There are no sediment screening levels or TELs for these compounds in current versions of the DMEF, SEF, or NOAA Squirt tables.

Potential Dredging Impacts

Sediment Resuspension

NorthernStar would use hydraulic cutterhead dredging to excavate the berth area. Studies by the COE indicate that cutterhead dredging generally results in lower sediment resuspension than other forms of dredging (e.g., clamshell or hopper barge) (COE, 1986; COE, 1988). Dredging operations to excavate the ship berth would suspend sediments and affect water quality. In general, dredging-related water quality impacts would include both the physical effects of suspended sediment and alterations of water chemistry due to the release of various chemical constituents associated with the sediment (see sections 4.3.2.2 and 4.3.2.3 for further discussion of water quality impacts). Additional discussion of potential sediment resuspension effects is included below.

Hydrodynamic and Sediment Transport Alterations

During initial scoping discussions, the NMFS raised a number of concerns related to potential impacts resulting from erosion, sedimentation, and changes in channel stability that could result from dredging of the proposed berth area at the LNG terminal. These issues included the potential for:

- changes in the morphology and hydraulics of the Clifton Channel;

- alteration of sediment transport in the main navigation channel and impacts on downstream Tenasillahe Island (in particular, the Lewis and Clark National Wildlife Refuge (LCNWR));
- changes in water circulation in the dock area to adversely affect shallow water habitat;
- scour at the shoreline from altered depth contours and from vessel berthing and unberthing movements at the terminal (including wave wash); and
- turbidity from dredge activity, including suspended solids concentration, size and duration of the plume.

Additionally, the NMFS requested information on the expected frequency and volume of maintenance dredging. To address the concerns of the NMFS, NorthernStar conducted hydraulic and sediment transport analyses using a combination of the RMA2 hydrodynamic model and the SED2D-WES sediment transport model (WEST, 2006). The RMA2 model is a two-dimensional, depth-averaged, finite element hydrodynamic numerical model developed by the COE. The SED2D-WES model is also a two-dimensional numerical model for calculating depth-averaged transport, deposition, erosion, and formation of stream-bed deposits in non-cohesive (i.e., sandy) sediments. The models were calibrated using measured data for a period in mid-March 2006. The calibrated models were then used to evaluate the hydrodynamic and sedimentation characteristics for a range of potential river flows. Based on historical stage and flow data, NorthernStar modeled four river flow conditions including:

- a low flow condition (discharge rate of 125,000 cubic feet per second (cfs));
- a 50 percent exceedance flow (210,000 cfs);
- a high winter or spring freshet condition (545,000 cfs); and
- an extremely high flow condition, equivalent to the 1996 flood event (846,000 cfs).

The results of the modeling show that changes in the hydraulic characteristics of the Columbia River and its channels caused by the proposed project would generally be minor. Specific responses for each of the NMFS initial concerns are presented below.

Based on the modeling conducted by NorthernStar, the proposed project would cause a reduction in stream flow through the Clifton Channel, resulting in a reduction of the water surface profile, shear stresses, and flow velocities through the channel. The changes in hydraulic conditions would occur over a 1.5-hour period at the peak of flood and ebb tides for low to average flows, and over the entire tidal cycle for high flows. This trend would increase slightly with a ship docked at the proposed terminal. The SED2D-WES results indicate that minor deposition may occur for the 50 percent exceedance flow along the Clifton Channel. However, the results do not show significant changes to the overall bed conditions in the Clifton Channel for the range of flows modeled. The small changes in the hydraulic characteristics associated with the proposed project are not expected to alter the form of the Clifton Channel. The reduction in flow through the Clifton Channel as a result of the proposed project also makes it unlikely that Clifton Channel would become the primary flow channel in the future.

Based on the SED2-WES results, the proposed project would have an influence on flow and sediment transport within the main navigation channel. The proposed turning basin would not cause a change in the velocities, depths, or sediment transport capacity within the area near the Lewis and Clark National Wildlife Refuge. However, modeling indicates that minor changes would occur north of this area and near the navigation channel. A comparison of the change in bed elevations after 90 days simulation of the 50 percent exceedance discharge indicates that the change in bed elevation within this

area would be minor (0.05 to -0.05 feet). However, the change would be more pronounced within the Columbia River near the navigation channel.

The results of the RMA2 hydrodynamic modeling indicate that the proposed project would cause a reduction of the velocities and shear stresses along the shoreline near the project site. Because of the reduction in the shear stresses and velocities along the shoreline, the proposed project would not cause increased bank erosion due to changes in depth contours resulting from dredging to construct the turning basin and mooring facilities. The potential for bank erosion from ship generated waves was investigated by NorthernStar and is discussed in detail in sections 4.1.2.3 and 4.1.3.3.

NorthernStar's design for the maneuvering basin includes side slopes of 3 (horizontal) to 1 (vertical), which is a reasonable slope for sediments in the area of the LNG terminal (Proudfit, 2008). However, we received comments on the draft EIS expressing concerns that lateral side slope migration could occur, resulting in impacts on critical shallow water habitat. Therefore, **we recommend that:**

- **NorthernStar should prepare a plan to monitor the side slopes of the maneuvering area after dredging. The plan should include slope protection measures, should such mitigation be necessary. The plan should be filed with the Secretary for the review and written approval of the Director of OEP prior to construction of the LNG terminal.**

Dredging activities would resuspend sediments and result in increases in total suspended solids (TSS) and turbidity. NorthernStar proposes to use hydraulic cutterhead dredging to excavate the proposed turning basin and berthing facilities. The maximum additional suspended solids concentration in the water column resulting from dredging activities would range from a high of 1 milligram per liter (mg/L) at the dredge site to less than 0.1 mg/L before reaching either Tenasillahe Island or Hunt Creek. These values are significantly less than the background concentration of 10 mg/L measured in the Clifton Channel as part of the field measurements for the hydrodynamic and sediment modeling study, and would generally be imperceptible. The size of the material introduced in the water column during the dredging activities would be almost entirely sand, ranging in diameter between 0.065 and 0.4 mm. As a result, the size of the sediment plume would be very small and confined to an area immediately surrounding the proposed dredging site. Additionally, the plume would diminish very quickly once the dredging activities are concluded. Based on recent monitoring of dredging operations for the Columbia River Channel Improvement Project, the COE has observed background turbidity values of 3 to 8 nephelometric turbidity units (NTU), and turbidity plumes from dredging operations returning to within 1 NTU of background within 45 seconds of the end of dredging (WEST, 2006).

Based on the sediment transport modeling, NorthernStar estimated the frequency and volume of required maintenance dredging. The modeling indicated that sediment deposition would occur uniformly over the entire turning basin. The average annual change in stream bed depth would be about 0.25 foot per year. Using this rate of deposition, the frequency and volume of maintenance dredging was determined for various target dredging depths. Generally, maintenance dredging would occur when the turning basin depth is raised by sediment additions to -42 feet CRD (1 foot above the project depth of -43 feet CRD). If dredging to maintain the turning basin occurred only when the target depth of -42 feet CRD was reached, the volume of sediment that would likely need to be removed would be about 80,000 cubic yards. Based on the hydrodynamic modeling NorthernStar conducted, this would occur about every 4 years under average conditions. If the river flows are abnormally high, maintenance dredging would be required more frequently.

All of the analyses discussed above were based on an assumption of uniform deposition within the turning basin. NorthernStar indicated that uniform deposition would be unlikely, and that greater

deposition would probably occur along the eastern part of the proposed turning basin, adjacent to the federal navigation channel. Additionally, maintenance dredging could be required more frequently as a result of large flood events. Although these events occur infrequently, they cannot be ignored because of the significantly larger volumes of sediment transported during these events. The results of the sediment transport modeling indicated that about 0.5 foot of deposition could occur from a flow rate of 864,000 cfs over a period of 10 days, similar to the 1996 flood event.

4.2.3 Pipeline Facilities

4.2.3.1 Existing Soil Resources

Information regarding soils along the proposed pipeline route is based on the Soil Surveys of Clatsop County, Oregon (USDA-SCS, 1988), Columbia County, Oregon (USDA-SCS, 1986), and Cowlitz County, Washington (USDA-NRCS, 2006) and SSURGO (USDA-NRCS, 2003). Additional information about the soils was obtained from Official Soil Series Descriptions (USDA-NRCS, 2004).

Detailed soil characteristics along the pipeline route and aboveground facilities were identified and assessed using SSURGO (USDA-NRCS, 2003). The SSURGO database is a digital version of the original county soil surveys developed by the NRCS for use with geographic information systems. It provides the most detailed level of soils information for natural resource planning and management. The mapping scale in the project area is generally 1:20,000, with a minimum delineation size of 4.0 acres. SSURGO is linked to an attribute database that gives the proportionate extent of the component soils and their properties for each map unit (USDA-NRCS, 1995).

SSURGO attribute data consist of physical properties, chemical properties, and interpretive groupings. Attribute data apply to the whole soil (e.g., listed hydric, prime farmland soils, or slope class) as well as to layer data for soil horizons (e.g., texture or permeability). The soil attribute data can be used in conjunction with spatial data to describe the soils in a particular area.

The proposed pipeline would be located in the Northern Pacific Coast Range, Foothills, and Valleys MLRA (see section 4.2.2.1) and the Willamette and Puget Sound Valleys MLRA. The dominant soils in the Willamette and Puget Sound Valleys MLRA are Xerolls. These moderately deep to deep, moderately fine to fine textured soils have a mesic temperature regime and mixed mineralogy. Thirty-nine percent of the soils that would be crossed by the pipeline are somewhat poorly drained or wetter. The majority of these soils are located in the low-lying areas on the Oregon side of the Columbia River. More well drained soils (61 percent) are located in the areas to the north and south of the river. The percentages calculated for the drainage classes do not include waterbody crossings which account for approximately 3 percent (0.9 mile) of the pipeline route.

Soil Characteristics

The soils along the proposed pipeline route and additional temporary work spaces were evaluated for characteristics that could affect pipeline construction or increase the potential for construction-related soil impacts. Appendix E lists by milepost the soil map units crossed by the proposed route and table 4.2.3-1 summarizes the miles of each soil series crossed in each county. Table 4.2.3-2 provides a summary of the significant soil characteristics that would be crossed by the proposed pipeline route in each county. Individual soil characteristics are discussed separately below.

TABLE 4.2.3-1

Soil Series Crossed by the Proposed Pipeline Route

County/Soil Series	Total Miles Crossed
Clatsop County, Oregon	
Alstony gravelly loam	2.28
Braun-Scaponia silt loam	0.70
Harslow-Kilchis very gravelly loam	0.35
Locoda silt loam	1.96
Scaponia-Braun silt loam	0.13
Udipsamments	0.62
Columbia County, Oregon	
Crims silt loam	1.62
Locoda silt loam	4.68
Udipsamments	0.79
Wauna silt loam	2.33
Wauna-Locoda silt loam	3.32
Cowlitz County, Washington	
Buckpeak silt loam	0.21
Camas cobbly loam	0.11
Carrolls loamy sand	0.08
Centralia silt loam	4.43
Clato silt loam	0.45
Cowlitz extremely gravelly sand	0.08
Edgewick silt loam	0.26
Germany silt loam	4.77
Hazeldell gravelly silt loam	0.39
Kalama gravelly loam	0.23
Kelso silt loam	0.72
Lithic Haplumbrepts	0.12
Newberg fine sandy loam	0.18
Olequa silt loam	0.15
Olympic silt loam	3.96
Riverwash	0.02
Rose valley silt loam	0.01
Sara silt loam	0.38
Sauvola loam	0.05

TABLE 4.2.3-2

Acreages and Characteristics of Soils Affected by Construction of the Bradwood Landing Pipeline ^a

County/State	Total Crossed ^b	Highly Water Erodible ^c	Highly Wind Erodible ^d	Prime Farmland ^e	Hydric Soils ^e	Compaction Prone ^f	Stony/ Rocky ^g	Shallow to Bedrock ^h	Revegetation Concerns ⁱ
Clatsop, Oregon	92.2 (6.2)	46.3 (3.5)	16.2 (0.6)	0.0 (0.0)	28.1 (2.0)	28.1 (2.0)	36.3 (2.6)	46.3 (3.5)	62.3 (4.1)
Columbia, Oregon	177.8 (13.2)	12.2 (0.8)	12.2 (0.8)	0.0 (0.0)	112.5 (8.1)	159.8 (12.0)	0.0 (0.0)	0.0 (0.0)	12.2 (0.8)
Cowlitz, Washington	223.7 (16.9)	193.1 (15.0)	2.4 (0.1)	43.3 (2.9)	2.6 (0.1)	0.1 (0.0)	12.4 (0.9)	1.5 (0.1)	178.7 (13.7)
Pipeline Total	493.7 (36.3)	251.7 (19.2)	30.8 (1.5)	43.3 (2.9)	143.2 (10.2)	188.0 (13.9)	48.7 (3.6)	47.8 (3.6)	253.5 (18.6)

^a Quantities represent acres based on a 100-foot-wide construction right-of-way and additional temporary workspace. The crossing length in miles is provided in parentheses. The area affected does not include access roads or open water. NorthernStar would use existing access roads that would not require modification or improvement and would, therefore, not represent additional soil impacts.

^b Represents total acres of soil affected in each county.

^c Soils designated by the NRCS as highly erodible or potentially highly erodible land.

^d Soils with a WEG classification of 2 or less.

^e As designated by the NRCS.

^f Includes soils in somewhat poor to very poor drainage classes with surface textures of sandy clay loam and finer.

^g Soils with a cobbly, stony, bouldery, shaly, very gravelly, or extremely gravelly modifier to the textural class of the surface layer and/or having a surface layer that contains greater than 5 percent by weight stones larger than 3 inches.

^h Soils identified as containing bedrock at a depth of 5 feet or less from the surface.

ⁱ Soils with a slope of greater than 8 percent and/or having a surface texture of sandy loam or coarser and moderately well to excessively drained.

Erosion

Erosion is a continuing natural process that can be accelerated by human disturbance. Factors that influence the degree of erosion include soil texture, soil structure, length and percent of slope, vegetative cover, and rainfall or wind intensity. Soils most susceptible to erosion by water are typified by bare or sparse vegetative cover, noncohesive soil particles with low infiltration rates, and moderate to steep slopes. Wind erosion processes are less affected by slope angles. Clearing, grading, and equipment movement would expose soils to water and wind erosion and, without adequate protection, result in discharge of sediment to adjacent waterbodies and wetlands. Soil loss due to erosion could also reduce soil fertility and impair revegetation as a result of topsoil loss.

Approximately 25 percent (121.1 acres) of the soils along the proposed pipeline route are designated as HEL that is susceptible to erosion by water. The majority of these soils are located in the Clatsop County and Cowlitz County portions of the proposed route where approximately 70 percent of the soils have an average slope of greater than 8 percent. In addition, 26 percent (130.6 acres) of the soils, all of which are located in Cowlitz County, are considered PHEL. PHEL consists of those soils that have the potential to be highly erodible, but cannot be designated as HEL without a field determination of slope percent and length. Ninety-four percent (462.9 acres) of the soils that would be crossed by the proposed pipeline have a WEG classification of 3 or higher and are therefore not susceptible to wind erosion. The susceptibility of the remaining soils to wind erosion could result in the loss of topsoil and potential dust hazards.

NorthernStar would use prescribed erosion control devices (e.g., silt fence, hay bales) and construction practices as specified in its pipeline ESC Plan for Oregon and SWPPP for Washington to minimize erosion during and after construction activities (see section 2.4). Temporary erosion control

devices would be installed immediately after initial ground disturbance and monitored as required throughout construction (e.g., daily in areas of active construction, weekly in areas with no active construction, within 24 hours of each 0.5 inch of rainfall). Erosion and sedimentation controls on the pipeline right-of-way would be inspected and maintained as necessary until final stabilization is achieved. NorthernStar would also implement dust mitigation measures, including the use of water trucks to moisten the right-of-way, to reduce impacts from wind erosion. Permanent revegetation of the disturbed soils would control erosion after construction is completed.

Prime Farmland

The USDA defines prime farmland as “land that is best suited to food, feed, fiber, and oilseed crops” (USDA-Soil Survey Division Staff, 1993). This designation includes cultivated land, pasture, woodland, or other lands that are either used for food or fiber crops or are available for these uses. Urbanized land and open water are excluded from prime farmland. Prime farmland typically contains few or no rocks, is permeable to water and air, is not excessively erodible or saturated with water for long periods, and is not subject to frequent, prolonged flooding during the growing season. Soils that do not meet the above criteria may be considered prime farmland if the limiting factor is mitigated (e.g., artificial drainage).

Approximately 8 percent (37.2 acres) of the soils that would be crossed by the proposed pipeline route are considered to be prime farmland. An additional 1 percent (6.1 acres) is considered prime farmland if a limiting factor is mitigated. Essentially all of the soils considered to be prime farmland along the proposed route are located in Cowlitz County (see table 4.2.3-2).

Potential impacts on prime farmland would include interference with agricultural drainage (if present), mixing of topsoil and subsoil, and compaction and rutting. These impacts would result primarily from trench excavation and backfilling, and vehicular traffic along the construction right-of-way. Impacts would be temporary and would not result in permanent conversion of prime farmland to non-agricultural uses. NorthernStar would minimize impacts on prime farmland by constructing the pipelines in accordance with its ESC Plan and SWPPP.

Hydric Soils

Hydric soils are defined as “soils that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper part” (Federal Register, 1994). Soils that are artificially drained or protected from flooding (e.g., by levees) are still considered hydric if the soil in its undisturbed state would meet the definition of a hydric soil. Hydric soils include very poorly, poorly, and some somewhat poorly drained soils.

Pipeline construction would affect approximately 143.2 acres of hydric soils. The majority (79 percent) of these soils would be located in Columbia County within the low-lying areas adjacent to the Columbia River. According to the Cowlitz County’s Critical Areas Ordinance map depicting NRCS hydric soils, these soil types also appear to be located adjacent to the Washington side of the Columbia River as well as around MP 28.0 and between MPs 34.0 and 35.0. Due to extended periods of saturation, hydric soils can be prone to compaction and rutting as discussed below. In addition, high groundwater levels associated with hydric soils could create a buoyancy hazard for the pipeline. NorthernStar would minimize rutting of hydric soils by using construction mats where hydric soils cannot support equipment and/or by employing low-ground-weight equipment according to its ESC Plan and SWPPP and our Procedures. Special construction methods such as concrete coating of pipe and other weighting methods would be used to overcome buoyancy hazards during operation of the pipeline.

Excavation of the pipeline trench in saturated soils could result in an increased trench width due to sloughing of unstable trench walls. In addition, larger spoil storage areas could be needed to accommodate the saturated material being removed and stockpiled along the right-of-way. NorthernStar has requested a variance from our Procedures to allow for a wider construction right-of-way through wetlands. While a wider construction right-of-way through wetlands may have additional impacts on hydric soils, we agree with NorthernStar that their request for a variance is justified to ensure the safe installation of the pipeline, because of the potential for a larger trench width due to slumping saturated soils in wetlands and the need to separate spoil piles (see section 4.4.1.3 for the FERC staff's conclusions regarding proposed modifications to our Procedures).

Compaction Potential

Soil compaction modifies the structure and reduces the porosity and moisture-holding capacity of soils. Construction equipment traveling over wet soils could compact and disrupt the soil structure, reduce pore space, increase runoff potential, and cause rutting. The degree of compaction depends on moisture content and soil texture. Fine-textured soils with poor internal drainage that are moist or saturated during construction are the most susceptible to compaction and rutting.

Approximately 38 percent (188.0 acres) of the proposed pipeline would cross soils prone to compaction. The majority of these soils are located in Columbia County in the low-lying areas adjacent to the Columbia River (see table 4.2.3-2). NorthernStar would minimize compaction and rutting impacts by using measures outlined in its pipeline ESC Plan and SWPPP and our Procedures (e.g., construction from timber mats, or low-ground-weight equipment) during construction in soft or saturated soils. As outlined in the FERC staff's Plan, one of the responsibilities of the environmental inspector is to advise the chief construction inspector when conditions (such as wet weather) make it advisable to restrict construction activities to avoid excessive rutting. In residential and agricultural areas, the environmental inspector also ensures compaction testing is performed to assess the need for corrective action. In residential and agricultural areas, subsoil compacted by construction would be disked prior to returning the segregated topsoil.

Stony/Rocky and Shallow to Bedrock Soil

Introducing rocks to surface layers may reduce soil moisture-holding capacity, resulting in a reduction of soil productivity. Additionally, some agricultural equipment may be damaged by contact with large rocks. The presence of rocks within the surface horizons and/or shallow bedrock may also create poor revegetation conditions.

Approximately 10 percent (47.8 acres) of soils crossed contain bedrock within 5 feet of the surface. The majority of these soils are located in Clatsop County (see table 4.2.3-2). About 10.1 acres of these soils contain bedrock classified as paralithic (weathered) that would not likely require special construction techniques. However, the proposed route would cross 37.7 acres of soils with a lithic contact (unweathered bedrock) within 5 feet of the surface that may require blasting or other special construction techniques during installation of the proposed pipeline (see section 4.1.4.4 for more details regarding blasting). Approximately 48.7 acres of stony/rocky soils would be crossed by the proposed route in Clatsop and Cowlitz Counties.

Revegetation Potential

Successful restoration and revegetation are important for maintaining soil productivity and protecting the underlying soil from potential damage, such as erosion. Soils crossed by the proposed project were identified as having a poor revegetation potential based on the surface texture, slope, and

drainage class. Revegetation in soils that have a coarse surface texture and are moderately well to excessively drained may prove to be difficult to revegetate. The drier soils have less water to aid in the germination and eventual establishment of new vegetation. The coarser textured soils also have a lower water holding capacity following precipitation, which could result in moisture deficiencies in the root zone and creating unfavorable conditions for many plants. In addition, steep slopes along the pipeline route may make the establishment of vegetation difficult. The clearing and grading of soils with poor revegetation potential could result in a lack of adequate vegetation following construction and restoration of the right-of-way, which could lead to increased erosion, a reduction in wildlife habitat, and negative visual impacts.

About 51 percent (253.5 acres) of the proposed pipeline would cross soils with revegetation concerns. The majority of these soils are located in Clatsop and Cowlitz Counties (see table 4.2.3-2). This is due to the fact that approximately 70 percent of the soils crossed in these counties have a slope of greater than 8 percent. In accordance with its ESC Plan and SWPPP, NorthernStar would mitigate the effects of poor revegetation potential by applying fertilizer, pH modifiers, and using mulch (where appropriate) to create a favorable environment for the re-establishment of vegetation. A seed mixture, developed through consultation with the ODFW, Washington Department of Fish and Wildlife (WDFW), and NRCS, and in accordance with landowner agreements, would be applied to re-establish vegetation following final grading. Revegetation in non-agricultural areas would be considered successful if, upon visual survey, the density and cover of non-nuisance vegetation are similar to adjacent undisturbed areas. In agricultural areas, revegetation would be considered successful if crop yields are similar to adjacent undisturbed portions of the same field.

Soil Contamination

Contamination from spills or leaks of fuels, lubricants, and coolant from construction equipment could adversely affect soils. The effects of contamination are typically minor because of the low frequency and volumes of spills and leaks. NorthernStar's pipeline ESC Plan and SWPPP contain measures to prevent and contain, if necessary, accidental spills of any material that may contaminate soils, and to ensure that inadvertent spills of fuels, lubricants, or solvents are contained and cleaned up in an appropriate manner.

A search of numerous federal, state, and tribal environmental records identified 10 potentially contaminated sites within 1,500 feet of the proposed project facilities (see table 4.2.3-3). Based on the distance of these sites from the proposed project area and the fact that soil and groundwater contamination either has not been reported or has been cleaned up for each facility, NorthernStar does not expect to encounter contamination from these sites during pipeline construction. Although the potential to encounter contaminated soils is relatively low, mismanagement of contaminated materials encountered during construction could result in serious impacts on soils and other sensitive resources. To ensure that personnel working on the project are prepared to deal appropriately with an unanticipated encounter with contaminated soils, we have recommended that NorthernStar prepare a CMMP for the proposed Bradwood Landing Project (see section 4.2.2.1).

TABLE 4.2.3-3		
Potential Contaminated Sites within 1,500 feet of the Bradwood Landing Pipeline		
Location	Description	Proximity to the Project Work Area
OP&R – Bradley State Wayside UIC, Highway 30, Clatsop, Oregon	Two septic fields and a greywater injection well.	1,100 feet west of MP 1.6
Former Koppers Wood Treating Site, Taylorville Road, Clatskanie, Oregon	Various contaminants from a former wood treating operation.	1,500 feet north of MPs 3.6 to 4.0
Westmart Foodstore, Columbia River Highway, Westport, Oregon	Gasoline spill from an UST in 1996. Cleanup complete in 1997.	The town of Westport is located 1,300 feet south of MP 5.6
River Front Road, Clatskanie, Oregon	Identified in the ODEQ spill records. Specific material or quantity not identified.	600 feet north of MP 10.6
Lammi Sand & Rock Products, Midland District Road, Clatskanie, Oregon	One UST decommissioned on site.	1,300 feet south of MP 10.1
Kynsi Construction, Inc., Midland District Road, Clatskanie, Oregon	Aboveground storage of antifreeze, unleaded gasoline and diesel fuel.	1,400 feet south of MP 10.1

Aboveground Facilities

Construction of aboveground facilities associated with the proposed pipeline would temporarily impact a total of about 5.0 acres of soil, of which 1.4 acres would be permanently converted to commercial industrial uses by operation of the facilities. Only about 2 percent (0.1 acre) of the soils within the aboveground facilities are considered prime farmland. An additional 12 percent (0.6 acre) of the soils within the proposed facilities are considered prime farmland only if they are artificially drained. However, the prime farmland soils within these facilities are not currently actively cultivated. Approximately 50 percent (2.5 acres) of the soils are considered PHEL or HEL that is susceptible to erosion by water. Forty-nine percent (2.5 acres) of the soils within the proposed facilities have a WEG of 2 or less and are therefore considered susceptible to wind erosion. NorthernStar would implement measures described in its pipeline ESC Plan and SWPPP to minimize potential soil impacts associated with the construction and operation of the proposed aboveground facilities.

Pipe Storage and Contractor Yards

NorthernStar has identified two pipe storage and contractor staging yards that would be used during the construction of the proposed pipeline. These yards would affect a combined 18.5 acres of land. This land has been previously developed so no additional impacts on the soils would be expected. The 9.1 acres of soil within Yard A in Columbia County are not considered prime farmland, susceptible to erosion by water, hydric, or prone to compaction. These soils are considered to be susceptible to wind erosion and have revegetation concerns. The 9.3 acres of soil within Yard B in Cowlitz County are considered prime farmland. However, these soils have been previously developed and are not currently used for active cultivation. In addition, the site would be returned to preconstruction conditions, so no permanent impacts on prime farmland would result from use of the site. These soils are not considered to be susceptible to erosion by wind or water or to have revegetation concerns. All of the soils at this pipe storage yard are considered hydric and prone to compaction. NorthernStar would implement measures

described in its pipeline ESC Plan and SWPPP to minimize potential soil impacts associated with the use of the two pipe storage and contractor yards.

4.2.3.2 General Impacts and Mitigation

Construction activities such as clearing, grading, trench excavation, backfilling, and the movement of construction equipment over work areas may result in adverse impacts on soil resources. Clearing removes protective cover and exposes the soil to the effects of wind, sun, and precipitation, which may increase the potential for soil erosion and the movement of sediments to sensitive areas. Grading and equipment traffic may compact soil, reducing porosity and percolation rates, which would result in increased runoff potential and decreased agricultural productivity. Trench excavation and backfilling could lead to mixing of topsoil and subsoil and may introduce rocks to the soil surface from deeper soil horizons. Contamination from spills or leaks of fuels, lubricants, and coolants from construction equipment could also impact soils.

NorthernStar's pipeline ESC Plan and SWPPP⁵ incorporate elements of the FERC's Plan and Procedures, state and county regulations and provisions, stormwater pollution prevention plans, and spill prevention and response procedures. Drafts of these plans were included in NorthernStar's JPA and JARPA. Final versions of these plans would be developed after a construction contractor has been selected prior to construction. We have reviewed NorthernStar's pipeline ESC Plan and its SWPPP and find that in many cases they lack specific procedures, and are less detailed than or do not provide equivalent or greater protections to the environment compared to our Plan. On the other hand, the pipeline ESC Plan and SWPPP contain BMPs and mitigation measures for items outside the scope of our Plan, such as spills prevention and cleanup, wind erosion and dust control, and project-specific seasonal work restrictions. To ensure that potential impacts on soils as well as vegetation are effectively minimized, **we recommend that:**

- **NorthernStar should revise its pipeline ESC Plan and SWPPP to include the measures from the FERC's Plan that provide greater protections. NorthernStar's revised plans should be filed with the Secretary for the review and written approval of the Director of OEP prior to construction of the pipeline.**

⁵ NorthernStar included its terminal ESC Plan and pipeline ESC Plan as part of its JPA, and included its SWPPP as part of its JARPA. NorthernStar's JARPA was filed with the FERC on November 6, 2006, and supplemented with a filing on November 22, 2006. NorthernStar also filed its JPA on November 22, 2006, and filed revisions to the JPA with the FERC on April 5, 2007. These documents are available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range. The FERC's Plan and Procedures are also available to the public on the FERC's Internet web page by clicking on Industries, Gas, Environment, Guidelines.

4.3 WATER RESOURCES

4.3.1 Groundwater

4.3.1.1 Regional Hydrogeologic Setting

According to USGS (2005a) there are three aquifer systems in the project vicinity: 1) the Unconsolidated Sediment Aquifer of the Holocene, Pleistocene, Pliocene, and Miocene; 2) the Miocene Basaltic Rock Aquifer System; and 3) the Pre-Miocene Rock Aquifer System. The stratigraphy of these aquifer systems is detailed in section 4.1.1. The coastal region of Oregon and Washington receives large amounts of precipitation, 40 to 80 inches per year (USGS, 2005a), that recharge the aquifers in the area.

The Unconsolidated Sediment Aquifer System underlies the western half of the project area and is also part of the Pacific Northwest Basin-Fill Aquifer System (USGS, 2005b), a system comprised of unconsolidated deposits that are largely alluvial in nature. In the vicinity of the proposed project, this system consists primarily of unconsolidated sand and gravel and is associated with lowland areas along the Columbia River. These unconsolidated deposits are the most prolific aquifers and are important sources of water for public supply, domestic, commercial, agricultural, and industrial demands (USGS, 2005a).

The Miocene Basaltic Rock Aquifer System occurs where more resistant uplands consist of thick basaltic lava flows (USGS, 2005a) and also underlies the terminal facility and much of the proposed pipeline route. Basaltic rock aquifers tend to have open spaces filled with secondary clay minerals, calcite, silica, or unconsolidated alluvium deposited by streams or in lakes. Except where such fill materials are coarse grained, they tend to markedly decrease the permeability of these aquifer systems.

Aquifers in pre-Miocene rocks are distributed along the coast of Oregon and Washington. These aquifers consist of several types of igneous and metamorphic rocks, consolidated sedimentary rocks, and volcanic rocks. Permeability varies greatly in these aquifers. The eastern half of the Cowlitz County segment of the proposed pipeline crosses over the Pre-Miocene Rock Aquifer System. The aquifers of this system are in mountainous areas, and the water is used mostly for domestic and agricultural supplies.

4.3.1.2 Waterway for LNG Marine Traffic

LNG carriers would not use groundwater and the LNG marine traffic would not have an impact on groundwater resources along the waterway.

4.3.1.3 LNG Terminal

The presence of alluvial sediments of the Unconsolidated Sediment Aquifer at the proposed LNG terminal site was confirmed by the geotechnical investigation (URS, 2005), which characterized local conditions based on site reconnaissance and soil borings (see section 4.1.3.1). The soil borings encountered groundwater beginning at depths ranging from 12 to 15 feet below the ground surface. The Upper Alluvial Sand sequence is interpreted as the first aquifer occurring beneath the site. Because alluvial sand and gravel aquifers are typically the most productive and widespread aquifers in the Pacific Northwest (Whitehead, 1994), both of the alluvial sand aquifers are expected to have water production potential.

Public Water Supply and Wells

To assess the expected productivity of the shallow alluvial aquifer underlying the proposed LNG terminal site, Groundwater Solutions, Inc. (GSI) compared the results of the soil borings with the Columbia River bathymetry data for the channel near the site. Based on the soil borings completed at the site, the relative depth of the Upper Alluvial Sand Sequence (approximately 0 to 60 feet below msl) is consistent with the elevation range of the Columbia River channel bottom (20 to 50 feet below msl). The Upper Alluvial Sand Sequence is also relatively uniform in thickness and laterally extensive; therefore, the permeability and thickness of the aquifer unit should be adequate to supply more than 150 gpm (the proposed water use from the well during construction and operation) to a properly constructed well at the site (GSI, 2006a). In addition, the observation that groundwater levels at the site fluctuate with the river and tidal elevations suggests the Upper Alluvial Sand Sequence extends laterally beneath the river channel, maintains connectivity with the Columbia River, and provides for an unlimited source of aquifer recharge (GSI, 2006a).

According to data provided online through the Drinking Water Program of the Oregon Department of Human Services (ODHS), no public groundwater supplies near the proposed Bradwood Landing LNG terminal site are currently impacted by contamination (ODHS, 2005). The closest community groundwater systems are for the Knappa Water Association, Westport Heights, and Wauna Water District. The closest of these communities is Wauna, about 3 miles south-southeast of the proposed LNG terminal site. The Wauna Water District system is operated by the local government, while the other two are privately operated but have completed source water assessments.

Overall, the proposed LNG terminal would avoid water supply wells and springs. A search of all wells in Clatsop County within a 2-mile radius of the LNG terminal site identified only one water supply well (however, some wells may not be included in the database – particularly older wells). This well is privately owned and it is believed to be about 0.5 mile from the LNG terminal. No springs were identified within 150 feet of the construction areas based on topographic maps or web-based information. Furthermore, the ODHS database of wellhead protection areas (ODHS, 2006) indicated that the LNG terminal site is not located within any wellhead protection areas.

The proposed project would not be located near any EPA-designated sole source aquifers listed under section 1424(e) of the Safe Drinking Water Act (EPA, 2006). The EPA defines a sole or principal source aquifer as one that supplies at least 50 percent of the drinking water consumed in the area overlying the aquifer, and for which there are no other reasonably available alternative drinking water source(s) that could physically, legally, and economically supply all those who depend upon the aquifer for drinking water should the aquifer become contaminated. Of the 13 sole source aquifers that have been designated in EPA Region 10 (i.e., Alaska, Idaho, Oregon, and Washington), none are near the proposed LNG terminal facilities. No petitions for sole source aquifers are currently under EPA review in Region 10.

Groundwater Quality

In general, groundwater quality in coastal Oregon and Washington is fresh, with low concentrations of dissolved solids (less than 1,000 milligrams per liter (mg/L)) and is normally suitable for most uses. However, in coastal areas, more saline waters can be found in some aquifers at depth (McFarland, 1983). Additionally, saltwater can contaminate freshwater aquifers by entering from the ocean through river estuaries, such as the Columbia River, or along faults (USGS, 2005a). This is particularly true of the Pre-Miocene Rock Aquifers. Groundwater quality in the alluvial aquifers would be expected to have low dissolved solids, but no site-specific evaluation has been conducted. No further water quality information is available for these shallow, discontinuous aquifers.

No potential sources of groundwater contamination in the immediate vicinity of the LNG terminal site were found in published literature (Cole, 2004) or on an interactive website maintained by the ODEQ (ODEQ, 2005a). The nearest site where groundwater contamination has been documented is the former Koppers Wood Treating Site, located approximately 3 miles south-southeast of the Bradwood Landing LNG terminal site along the Columbia River. Groundwater beneath the former Koppers Wood Treating Site is flowing toward the Columbia River and, therefore, would not impact the LNG terminal site.

The ODEQ's Leaking Underground Storage Tank Cleanup Site Database (ODEQ, 2005b) shows no sites in the vicinity of the proposed Bradwood Landing LNG terminal. Of the closest three sites, two were located in Knappa and one in Westport, all several miles from the proposed LNG terminal site. Since cleanup was completed and the status of all three sites is "closed," these sites are not expected to have an impact on the groundwater at the Bradwood Landing LNG terminal.

Two industrial solid waste facilities were found in Clatsop County (ODEQ, 2005c). The Wauna Cogeneration Project and Wauna Mill Landfill, which are both apparently associated with a pulp and paper mill that operates on the former Koppers Wood Treating Site. The Wauna Cogeneration Project is not expected to have any impact on groundwater conditions beneath the LNG terminal site for the same reasons as those discussed above for the former Koppers Wood Treating Site.

Oregon's Underground Injection Control (UIC) database (ODEQ, 2005d) lists sites that involve placement of fluid below the ground or subsurface. The closest UIC site to the Bradwood Landing LNG terminal is found in Knappa, at least 3 miles away. Therefore, it is not expected to have any impact on the groundwater beneath the facility.

It is not known whether past activities at the former sawmill facility at Bradwood have affected groundwater conditions at the site. As described in section 4.2.2.1, AMEC conducted a Phase 1 Environmental Site Assessment in August 2005 that identified several RECs that could potentially affect or have already impacted groundwater conditions at the site (AMEC, 2005). However, groundwater at the site would not be used for drinking.

Groundwater Uses and Withdrawals

Groundwater would be used at the LNG terminal site during construction and operation (see table 4.3.1-1). An application for a limited water use license to use groundwater during construction of the LNG terminal has been submitted by NorthernStar to the ODWR.

To supply water to the LNG terminal, a single, 6-inch-diameter water well with a total depth of approximately 90 feet would be installed at the location shown on figure 2.1.3-1 (GSI, 2006b). A submersible pump would be installed in the well to supply water at a rate not to exceed 150 gpm. Water from the well would be pumped to an 180,000-gallon tank for storage and would be delivered from the tank to the construction site through approximately 1,000 feet of 3-inch-diameter steel pipe.

TABLE 4.3.1-1

Potential Water Intakes and Discharges Associated with the Bradwood Landing Project

Purpose	Volume (millions of gallons)	Timeframe	Rate	Structure/Location Source
Construction				
Water Intake				
Personal/sanitary ^{a, b}	7.7	Intermittent	Variable	Groundwater well
Vehicle wheel washing ^b	2.0	Intermittent	Variable	Groundwater well
Hydrostatic testing of piping within LNG terminal	1.5	One-time use	Variable	Groundwater well
Concrete making ^b	0.9	Intermittent	Variable	Groundwater well
Initial charging of SCVs	0.2	One-time use	Variable	Groundwater well
Hydrostatic testing of LNG tanks	60.0 ^c	One-time use	4,000 gpm	Columbia River
Soil compaction and ground improvements	15.0	Intermittent	160 gpm	Columbia River
Hydrostatic testing of pipeline	9.0	One-time use	2,000 gpm	Columbia River
Water Discharge				
Personal/sanitary ^{a, b}	7.7	Intermittent	Variable	Septic system
Vehicle wheel washing ^b	2.0	Intermittent	Variable	Groundwater
Hydrostatic testing of piping within LNG terminal	1.5	One-time use	Variable	Groundwater or Columbia River
Hydrostatic testing of LNG tanks	60.0 ^c	One-time use	5,000 gpm	Columbia River
Soil compaction and ground improvements	15.0	Intermittent	Variable	Columbia River via log pond
Hydrostatic testing of pipeline	9.0	One-time use	Up to 1,000 gpm	Upland site in straw bale enclosure
Pipeline trench dewatering	Minimal	Intermittent	Variable	Upland site (vegetated area or to a dewatering structure)
Operation				
Water Intake				
Personal/sanitary	0.64	Annually	Variable	Groundwater well
Landscape irrigation	0.41	Annually	Variable	Groundwater well
Ballast water and ship engine cooling ^d	20 - 50	About every 3 days	Up to 35,000 gpm	Columbia River
Testing of fire suppression system	0.26	Weekly	4,400 gpm	Columbia River
Water Discharge				
Personal/sanitary	0.64	Annually	Variable	Septic system
Landscape irrigation	0.41	Annually	Variable	Groundwater
Ship engine cooling ^{d, e}	20 - 50	About every 3 days	Variable	Columbia River
Condensate water from SCVs	0.23	Daily	160 gpm	Columbia River
Testing of fire suppression system	0.26	Weekly	Up to 4,400 gpm	Columbia River

^a NorthernStar currently plans to use portable bathrooms during construction, which would eliminate the need for groundwater withdrawal for personal/sanitary use.

^b Water appropriation and discharge would occur over a period of 3 years.

^c Assumes that hydrostatic test water for the LNG tanks would not be recycled; however, NorthernStar plans to schedule construction activities to enable water used to test the first tank to be reused to test the second tank.

^d NorthernStar proposes to offer incentives to retrofit LNG carriers with a water intake system that would allow the water supplied to the carriers to be first used to cool the engines and then used to fill the ballast tanks, which would result in the total volume of water withdrawn and discharged being less than that presented in this table.

^e In the case that ships arriving at the LNG terminal have not been retrofitted to use the screened water intake system, water used to cool the engines would be discharged to the Columbia River.

NorthernStar estimates the maximum volume of groundwater required during the 3-year construction period would be 12.3 million gallons, although the rate of water use is not expected to be constant throughout the entire construction period. To provide 12.3 million gallons of water during the 3-year construction period, the well would be operated about 5 percent of the time. Water use associated with general construction activities such as dust suppression, road grading, concrete making, personal/sanitary use, and truck wheel washing would occur at varying rates depending on the intensity of construction activities; however, the maximum volume of groundwater needed for these uses is estimated to be 10.6 million gallons. Initial charging of the vaporizers and hydrostatic testing of the piping would be done during the last year of construction. The volume of groundwater needed for charging vaporizers and testing piping is estimated to be 1.7 million gallons. Actual groundwater use during the construction period is expected to be less than the estimated maximum. Currently, NorthernStar is planning to contract with a vendor for supply and maintenance of portable bathrooms during the construction period. If portable bathrooms are used, then groundwater use could be reduced by as much as 7.7 million gallons. Small volumes of groundwater also may be pumped on a temporary basis for dewatering during construction of the terminal facility.

The well and the 180,000-gallon storage tank used to supply water for the temporary construction activities would also be used to supply non-potable water during LNG terminal operations. Water would be pumped from the well to the storage tank and then distributed around the LNG terminal facility. Annual use of groundwater at the LNG terminal is estimated to be 1.05 million gallons. Of this amount, 0.41 million gallons would be used annually for landscape irrigation and 0.64 million gallons would be used annually for personal/sanitary purposes. Annual groundwater use during operations at the LNG terminal would be much lower than the maximum capacity of the well, and the well would operate about 1.3 percent of the time.

The on-site water well would be about 200 feet from the Columbia River, about 900 feet from Hunt Creek, and 800 feet from any wetlands. The mean sustained discharge from the well would only be about 2.0 gpm, and because the soils surrounding the well are very permeable, the cone of depression produced by the well would be small. During the geotechnical study, water levels in the boreholes were observed to vary with the tide, suggesting that river water would be readily drawn into the aquifer and would minimize drawdown at the well. The well would be unlikely to have an effect on Hunt Creek or the wetlands, and any effect on flow in the Columbia River would be negligible.

Disposal of Water to the Ground

The elevation of the LNG terminal site would be raised by the placement of dredged material from the ship berth and maneuvering area. The dredged material would be piped to the site from a hydraulic cutterhead dredge. All or most of the dredge water is expected to infiltrate into the ground. During terminal construction, stormwater and water used for vehicle wheel washing, hydrostatic testing of the LNG storage tanks, and soil compaction would be disposed of by infiltration into the ground. During LNG terminal operation, excess irrigation water, sanitary wastewater, and most stormwater would be disposed of by infiltration into the ground. The soils at the site would be sufficiently permeable, even after compaction, for effective infiltration of water without major ponding or surface runoff. The water table would be 22 to 30 feet below the finished grade, depending on the final site elevation.

Vehicle wheel washing would occur on a paved wash pad near the point where the access road crosses the realigned railroad. No soaps or surfactants would be used for vehicle wheel washing and the temperature of water used for washing would be equal to that of water being stored in the on-site storage tank (no hot water would be used). Excess water from the pad would be discharged to a two-cell sedimentation/infiltration pond. The first cell of the pond would provide treatment by allowing settling of

sediment. Clarified water from the first cell would be conveyed to the second cell and infiltrated into the ground. A total of 2 million gallons of vehicle wheel washing water would be discharged.

During construction, all stormwater runoff would be infiltrated into the ground in accordance with the conditions contained in the NPDES permit issued by the ODEQ. NorthernStar has stated that it anticipates discharging approximately 1.5 million gallons of hydrostatic test water from testing the piping to the ground at an upland location that has not yet been determined. This discharge would occur once during the third year of construction. However, NorthernStar has stated that this discharge may be to the Columbia River. For this reason, potential impacts from the discharge of hydrostatic test water from the piping to the Columbia River are also discussed in section 4.3.2.3.

Once operations begin at the LNG terminal, sanitary wastewater from toilets, sinks, and showers in the office and maintenance/service buildings would be conveyed to an underground septic tank and drainfield or other approved secondary treatment and disposal configuration, if site conditions are not appropriate for a drainfield (see figure 2.1.3-1). A permit would be obtained from the ODEQ for the septic system, which would be sited and sized in accordance with the ODEQ requirements and recommendations. The septic system would be sized according to the number of employees on site during any given day (although 65 permanent employees would be hired for operation of the LNG terminal, NorthernStar anticipates that 50 employees would be on site during an average day), assuming a water use rate of 35 gallons per person per day, and shower facilities on site (Cox, 2006). An estimated 0.64 million gallons per year would be discharged to the septic system.

The drainfield or other approved secondary treatment and disposal system would be designed and installed based on the results of permit requirements and a site evaluation, which cannot be conducted until fill has been added to bring the site to final grade. The location of the system would follow the minimum separation distances specified in table 1 of OAR 340-71-0220. If a drainfield is not recommended for treatment and disposal of wastewater, other alternatives would be considered and could include the use of a pretreatment system, a sand filter, or a holding tank. There would be no potential for surface water contamination because the system would comply with the ODEQ's requirements.

If a septic tank and drainfield system are used, the tank outlet and the drainfield would be 3 to 5 feet below grade. The finished site elevation would be at least 20 feet NAVD, so the tank outlet and drainfield would be at an elevation of at least 15 feet NAVD. The 500-year flood elevation is 13.83 feet NAVD. Therefore, it is highly unlikely that the septic system would be inundated by surface waters. Other septic treatment alternatives may require installation of systems at grade instead of below grade, which would further reduce the potential for inundation.

Most water applied to landscaped areas would evaporate or be used by plants. A portion of the water used for irrigation, approximately 0.08 million gallons per year, would infiltrate into the ground. During operation, stormwater runoff would be collected in shallow infiltration ditches and routed to unlined settling ponds for infiltration into the ground in accordance with the conditions contained in the NPDES permit issued by the ODEQ. The stormwater retention ponds would be large enough to hold the volume of runoff generated from a 100-year storm.

Impacts and Mitigation

In general, construction and operation of the LNG terminal would have little or no adverse effect on groundwater resources. Potential impacts that could occur would be avoided or minimized through appropriate construction and hazardous material handling practices.

Construction and operation activities that could adversely impact groundwater quality include inadvertent releases from the refueling of construction equipment and the transportation and storage of petroleum and hazardous materials. In order to minimize potential impacts on groundwater resources resulting from the construction of the LNG terminal, NorthernStar has developed a terminal ESC Plan that contains BMPs for management of stormwater during construction as well as containment and management of fuels, lubricants, and other hazardous materials that may be used during construction. For example, fuel for construction vehicles would be stored in aboveground tanks located over a concrete slab with a perimeter curb to provide secondary containment. If chlorination and dechlorination of hydrostatic test water is required, the tanks containing sodium hypochlorite and sodium bisulfite would be stored on containment pallets. To avoid any potential impacts on groundwater quality as a result of the infiltration of stormwater runoff during construction, stormwater runoff from the wheel washing pad would be treated before disposal.

Blasting is currently proposed at the extreme southwestern part of the LNG terminal, where basalt may be mined to make aggregate material for use during on-site construction and along Clifton Road, as described in section 2.4.1.1. Blasting carried out at the LNG terminal site would be conducted before installation of the on-site water well.

Although the potential to encounter contaminated groundwater is relatively low during terminal construction, mismanagement of contaminated groundwater encountered during construction could result in impacts on surface water and other sensitive resources. In addition, the identification of RECs at the proposed LNG terminal site indicates that contaminated groundwater could be present at the site. We have recommended that NorthernStar prepare a CMMP that would specify the procedures to be followed to identify, characterize, and properly manage potentially contaminated materials, including groundwater (see section 4.2.2.1). The CMMP would be submitted to the appropriate agencies for approval before construction.

The overall effects on the groundwater system from dewatering during the construction of the LNG terminal would likely be small and temporary. Based on the relatively low volumes expected to be withdrawn and the proximity of the site to the Columbia River, a potential source of groundwater recharge, the likelihood of drawing off-site groundwater contaminants to the site through such dewatering activities is considered to be low.

4.3.1.4 Pipeline Facilities

On-line water well databases for Oregon (ODEQ, 2006a) and Washington (WDE, 2006a) were reviewed to identify aquifers within the excavation depth of the pipeline. More than 90 percent of the water well reports indicated that first-encountered groundwater was deeper than the pipeline excavation depth; however, some water well reports indicated that first-encountered groundwater was within pipeline excavation depth. Groundwater within the pipeline excavation depth occurs in small, discontinuous aquifers encountered as shallow as 3 feet below ground surface. The lithology of the sediment within the pipeline excavation depth is generally silty or clayey, and groundwater yields are, therefore, low. The wells where groundwater was encountered within pipeline excavation depths are screened in deeper aquifers; therefore, groundwater within the pipeline excavation depth is not used for domestic, irrigation, or municipal purposes.

Public Water Supply and Wells

NorthernStar conducted a search for records of public and private water wells along the proposed pipeline route (ODEQ, 2006a; WDE, 2005a). The water well databases do not provide exact coordinates for each well but instead give the location by township, range, section, and quarter-quarter section. The

well location is specified as the center of the quarter-quarter section. The wells identified within any quarter-quarter section crossed by the pipeline are listed in table 4.3.1-2.

Location (MP)	Well Number	Primary Use
20.87	270618	Domestic
21.03	346986	Domestic
21.03	356385	Domestic
21.03	270240	Domestic
21.03	10172	Domestic
27.57	271657	Domestic
31.72	1913	Domestic
31.72	1914	Domestic
31.72	8049	Domestic
31.72	1395	Domestic
31.72	8050	Domestic
31.72	1394	Domestic
31.72	3029	Domestic
31.72	3030	Domestic
33.70	314350	Domestic
33.70	326653	Domestic
33.87	10043	Domestic
34.11	387597	Domestic
35.80	10193	Domestic
35.80	60589	Domestic

No private wells potentially within 150 feet of the proposed pipeline construction right-of-way were identified in Oregon. Twenty private wells were identified in Cowlitz County, Washington. The database contained no municipal water wells potentially within 400 feet of the construction workspace of the proposed pipeline in either Oregon or Washington. NorthernStar would work with property owners along the pipeline route to identify new or unregistered wells located within or near the right-of-way that are not included in the above table.

No springs were identified within 150 feet of the proposed pipeline construction areas based on topographic maps or web-based information. The original pipeline alignment was adjusted to avoid a water supply spring identified by a landowner at approximate MP 31.1 (see table 3.1.8-2). If additional springs are identified as discussions with landowners proceed, NorthernStar would work with the landowner to minimize impacts on any springs located near the pipeline construction work space.

The State of Washington Department of Health (WDOH) has identified wellhead protection areas to keep groundwater recharge areas directly contributing to the water being withdrawn from a public water supply well safe from potential sources of contamination. A review of a database of wellhead protection areas (WDOH, 2006) indicated that seven wellhead protection areas in Cowlitz County are located within 0.25 mile of the proposed pipeline. The seven wellhead protection areas were defined by the default 1,000-foot radius approach (WDOH, 2006). The wellhead protection areas are:

- Robertson Road Water #1 – 1,000-foot wellhead buffer is at or near the proposed pipeline centerline at approximate MP 20.5;

- Crow Butte – essentially the same location as Robertson Road Water #1; 1,000-foot wellhead buffer is at or near the proposed pipeline centerline at approximate MP 20.5;
- Illahee Water – 1,000-foot wellhead buffer is within approximately 1,000 feet of the proposed pipeline centerline, at approximate MP 21.5;
- Allen Creek Water – 1,000 foot wellhead buffer intersects the northern edge of the 0.25-mile search corridor at approximate MP 33.0;
- Lone Fir Tavern Inc. – 1,000-foot wellhead buffer crosses the proposed pipeline centerline at approximate MP 35.0, and an HDD exit hole location is within this range;
- All Season Landscapes & Nursery – 1,000-foot wellhead buffer crosses the proposed pipeline centerline at approximate MP 35.2, and an HDD exit hole location is within this range; and
- LDS Church – 1,000-foot wellhead buffer crosses the proposed pipeline centerline at approximate MP 35.4.

The ODHS database of wellhead protection areas (ODHS, 2006) indicated that no wellhead protection areas are located within 0.25 mile of the proposed pipeline centerline in Clatsop or Columbia Counties, Oregon. The proposed pipeline would not be located near any EPA-designated sole source aquifers. Sole source aquifers are further described in section 4.3.1.3.

In areas where nonpoint source activities have resulted in groundwater contamination, a Groundwater Management Area (GWMA) is declared. No GWMAs are located near the proposed Bradwood Landing pipeline route in Washington or Oregon. Oregon has three declared GWMAs, the nearest of which is the Southern Willamette Valley GWMA, located over 100 miles south of the project area (ODEQ, 2005e). Additionally, the only GWMA designated in Washington, the Columbia Basin GWMA, is in southeast Washington and would not be affected by the pipeline facilities (Columbia Basin GWMA, 2005).

No declared critical groundwater areas are present within Clatsop and Columbia Counties (ODWR, 2005). However, Sweet et al. (as cited in ODEQ, 2003) reported that the aquifer that occurs in the alluvium between Wauna and Port Westward along the Columbia River is a “sensitive aquifer” of the North Coast Basin. The Bradwood Landing pipeline would pass over this aquifer, close to the Columbia River in this area. Between approximate MPs 33.8 and 34.9 the pipeline appears to cross an area designated as an aquifer recharge area in Cowlitz County’s Critical Areas Ordinance.

Groundwater Quality

The Wauna Mill Landfill is located adjacent to the proposed pipeline between MPs 2.4 and 2.6. The landfill was permitted and began operations in the early 1980s. Between the early 1980s and early 1990s, the landfill was primarily utilized as a receptacle for pulp sludge. The sludge stream was then diverted to boilers to produce steam and energy for the plant’s operation. Since the 1990s, the primary material for the landfill site has been the plant’s residual lime and ash spoils. The landfill is situated downgradient from the proposed pipeline right-of-way and the water table is likely below the lowest portion of the landfill, which is situated about 500 feet from the proposed easement. All but one of the landfill’s monitoring wells are situated downgradient and are not currently monitored for methane gas. According to Georgia-Pacific personnel, there are no reported groundwater contamination issues.

To avoid any potential wicking or flow of groundwater down or through the pipeline ditch, NorthernStar proposes to install a combination of sandbag dams and bentonite plugs at appropriate intervals along the ditch line where it parallels the existing landfill. This would effectively prevent the pipeline excavation from providing a conduit for groundwater flow.

Since the early 1990s, the landfill has not received waste that has the potential to produce methane gas. While the sludge has some potential for producing methane, the addition of lime and ash would have significantly impaired the potential for methane production by elevating the pH, lowering the moisture content of the soils, decreasing soil permeability, and creating an aerobic environment.

The landfill is located within a former clay quarry that was used by Georgia-Pacific to excavate clay for use within their paper making processes. This indicates that the soils nearby are likely fine-grained as well and are also relatively impermeable. In addition to the lack of porosity/permeability required for migration of landfill gasses any appreciable distance, methane gas production typically peaks within 2 years of placement and cover of the organic waste (Tchobanoglous et al., 1993). Combining these factors with the distance between the pipeline and landfill (in excess of 700 feet) indicates that the potential for the pipeline trench to act as a conduit for gas migration is very low.

As described in section 4.2.3.1, a search of environmental records (Environmental Data Resources, 2006) identified 10 potentially contaminated sites within 1,500 feet of the proposed project facilities (see table 4.2.3-3). The distance of these sites from the proposed project area, the groundwater flow direction, and the fact that soil and groundwater contamination either has not been reported or has been cleaned up for each facility suggest they would be very unlikely to have an impact on groundwater in the pipeline project area. Therefore, it is unlikely that NorthernStar would encounter contamination from these sites during pipeline construction.

Groundwater Uses and Withdrawals

Some groundwater withdrawals may occur as a result of dewatering operations during construction of the pipeline. Temporary trench dewatering may be necessary at limited areas along the pipeline corridor where the water table is near the ground surface.

Impacts and Mitigation

In general, construction and operation of the Bradwood Landing pipeline would have little or no adverse effect on groundwater resources, including designated wellhead protection areas. Potential impacts from accidental spills associated with construction equipment would be avoided or minimized through appropriate construction and hazardous material handling practices.

Construction and operation activities that could adversely impact groundwater quality include inadvertent releases from the refueling of construction equipment and the transportation and storage of petroleum and hazardous materials. In order to minimize potential impacts on groundwater resources resulting from the construction of the pipeline, NorthernStar has developed a pipeline ESC Plan (Oregon), a SWPPP (Washington), and a *Waterbody and Wetland Construction and Mitigation Procedures Plan* containing BMPs for management of stormwater during construction as well as containment and management of fuels, lubricants, and other hazardous materials that may be used during construction.

A cluster of private water wells is apparently located in close proximity to the proposed pipeline centerline at MP 31.7. NorthernStar would work with the owners of these wells and the other wells listed in table 4.3.1-2, as well as other property owners along the pipeline route, to confirm the exact locations of any wells within 150 feet of the construction area, and would identify and mark, as appropriate, any

undocumented water wells during preconstruction surveys. NorthernStar has prepared a preliminary well protection plan to address the effects of HDD and trenching activities. In addition, NorthernStar would develop a final well protection plan that would include at least the following activities, actions, or prohibitions: 1) fueling of vehicles and storage of fuel or hazardous materials would be prohibited within 200 feet of the wells; 2) blasting activities would be prohibited within 100 feet of the wells; and 3) monitoring would be performed before, during, and after construction within 150 feet of the wells. In the event a water well is damaged as a result of the construction, NorthernStar would arrange for an immediate temporary source of potable water, if required, and provide for the repair of the well or replacement of the water supply.

During pipeline construction activities, it is possible that HDD boreholes could penetrate local shallow aquifers. However, these activities are not expected to impact groundwater conditions other than in the immediate vicinity of the borehole, where bentonite drilling mud could result in localized alteration of aquifer hydraulic properties. Additionally and as mentioned in the preceding paragraph, wells located within 150 feet of the construction area would be monitored to evaluate water quality, which would detect any localized changes that might occur in response to the HDD activities.

Shallow groundwater can lead to the problem of pipeline buoyancy (i.e., the pipeline “floats” to the surface). NorthernStar would mitigate this impact by coating the pipe with a minimum of 4 inches of concrete to maintain negative buoyancy in areas of shallow groundwater (typically wetlands).

Blasting is not expected to be necessary for pipeline installation. However, in the event that blasting is required for pipe trench excavation, care would be taken to prevent damage to underground structures such as well casings. NorthernStar would work with the landowners of nearby wells to establish a well monitoring program, such as described above, for wells that might be affected by the vibrations generated by blasting.

Although the potential to encounter contaminated groundwater is relatively low during pipeline construction, mismanagement of contaminated groundwater encountered during construction could result in impacts on surface water and other sensitive resources. Before construction, we have recommended that NorthernStar prepare a CMMP that would specify the procedures to be followed to identify, characterize, and properly manage potentially contaminated materials, including groundwater (see section 4.2.2.1). The CMMP would be submitted to the appropriate agencies for approval before construction.

Any trench dewatering operations conducted for pipeline construction would be brief, typically lasting several days or less. Potential impacts on the groundwater would include minor fluctuations in groundwater levels and/or increased turbidity within the aquifer adjacent to the activity. Most alluvial aquifers exhibit moderate to rapid recharge and groundwater movement. Therefore, such effects would be temporary. If there is adequate vegetation to function as a filter medium, discharge would be directed to the vegetated land surface to control erosion. Where adequate vegetation is absent or in the vicinity of waterbodies or wetlands, trench water would be pumped into a filter bag or settling basin constructed of hay bales or silt fence so that silt-laden water would be filtered before release from the construction right-of-way. These practices would minimize the impacts on groundwater quality as the water removed from open trenches would be allowed to infiltrate back into the aquifer in the immediate vicinity of trenching activities.

If contaminated groundwater is encountered during trench dewatering activities, in addition to implementing the CMMP, the groundwater removed from the trench would be stored in Baker tanks, tested, and disposed of in accordance with local and state regulations. Trench dewatering would be conducted in compliance with applicable permits. As a result, impacts on groundwater associated with trench dewatering are not expected to be significant.

4.3.2 Surface Water

4.3.2.1 Surface Water Regulations and Standards

Federal Regulations

Construction of project facilities that affect waters of the United States would be regulated by the COE under section 10 of the RHA and section 404 of the CWA. Section 10 of the RHA prohibits the creation of any obstruction to the navigable capacity of any waters of the United States without specific approval of the COE. Section 404 of the CWA regulates the discharge of dredged or fill material into waters of the United States.

In addition to the COE permitting requirements, NorthernStar's proposed pipeline installation, LNG terminal development, and dredging activities would need to comply with section 401 of the CWA. NorthernStar would be required to obtain a section 401 water quality certificate demonstrating that the discharges associated with the project comply with federal and state water quality standards. The state agencies responsible for section 401 water quality certifications are the ODEQ and the WDE. NorthernStar would also need to certify that its project is consistent with the enforceable policies of the CZMA (see section 4.7.2.4).

Oregon Water Quality Regulations and Standards

Pursuant to the federal CWA, the ODEQ lists Oregon waterbodies that remain out of compliance with ambient water quality standards after conventional water pollution controls have been implemented. The lower Columbia River is listed as out of compliance for PCBs, arsenic, and water temperature (ODEQ, 2007).

The mainstem Columbia River has its own set of standards and policies that the ODEQ designed and enforces (under OAR 340-41), which include the following:

- the 7-day-average maximum temperature must not exceed 68.0 °F;
- coldwater refugia must be distributed so as to allow salmon and steelhead migration without significant adverse effects from higher water temperatures elsewhere in the waterbody;
- the seasonal thermal pattern in the Columbia River must follow the natural seasonal thermal pattern;
- pH values must be in the range of 7.0 - 8.5 (from the mouth of the river to CRM 309); and
- unless authorized by the ODEQ, total dissolved solids should not exceed 200 mg/L on the mainstem Columbia River (CRMs 120 - 147 and 210 - 309), or 500 mg/L for all other parts of the mainstem.

Water Quality Limited Waters (OAR 340-041-0046)

The state of Oregon identifies receiving streams as water quality limited through the biennial assessment report, as required by 305(b) of the CWA. The report gives details of the area of waterbody or segment of stream that is limited, the time of year water quality standards violations occur, and the

parameter(s) of concern. The water quality limited list is placed on public notice and reviewed through a public hearing process. ODEQ may add waterbodies to the list between status assessment reports by following the same process of placing the action on public notice and conducting a public hearing.

In the case of interstate waterbodies, the portion of the waterbody within Oregon's border is assessed. For waterbodies designated as "water quality limited," requests for load increases may be considered using the process set out in OAR 340-041-0004(9)(b).

Section 303(d) List

Section 303(d) of the CWA requires that states periodically prepare a list of all surface waters in the state for which beneficial uses, such as drinking, recreation, aquatic habitat, and industrial use are impaired by pollutants. This list is prepared by the ODEQ and typically provided biennially to the EPA as required under section 305(b) of the CWA. The 2004/2006 list is the most recent list that was approved by the EPA for Oregon.

The water quality standards are not being met for the Columbia River's beneficial use of fish habitat. The portion of the Columbia River between CRMs 0 and 306.1 is on ODEQ's 303(d) water quality-limited list for temperature (year-round, non-spawning). In addition, between CRMs 35.2 and 98.0, the Columbia River is listed for exceeding total maximum daily loads (TMDL) for arsenic, dichlorodiphenyl-trichloroethane (DDT), and PCBs year-round. Although previously listed for dissolved oxygen levels, fecal coliform, and temperature, the Clatskanie River has been removed from the 303(d) list.

Outstanding Resource Waters

Outstanding Resource Waters (ORW) are existing high quality waters that constitute an outstanding state or national resource. Oregon's rules establish a classification of ORWs. Oregon's Environmental Quality Commission has the authority to classify waterbodies as ORWs but has not yet developed procedures for classifying waterbodies using this system.

Washington Water Quality Regulations and Standards

The WDE is responsible for water quality standards for all surface waters within the state as required under section 303(c) of the CWA. The WDE has developed a classification system to describe the highest designated use(s) and associated minimum water quality requirements for surface waters in Washington. The purpose of the WDE's Water Quality Standards for Surface Waters (WAC 173-201A) is to establish water quality standards consistent with public health and public enjoyment, and the propagation and protection of fish, shellfish, and wildlife. The water use and quality standards are established in conformance with present and potential uses of the surface waters and in consideration of natural water quality potential and limitations. The Water Quality Program in WAC 173-201A refers to "existing and designated uses" of waterbodies. Existing uses are defined as "those uses actually attained in fresh or marine waters on or after November 28, 1975, whether or not they are designated uses. Introduced species that are not native to Washington, and put-and-take fisheries comprised of nonself-replicating introduced native species, do not need to receive full support as an existing use." Designated uses are defined as "those uses specified in this chapter (WAC 173-201A) for each waterbody or segment, regardless of whether or not the uses are currently attained." Designated uses for those waterbodies crossed by the Bradwood Landing Project include aquatic life, recreational, water supply, and miscellaneous uses (e.g., wildlife habitat, harvesting, commerce/navigation, boating, and aesthetics). Like Oregon, the State of Washington also designates certain waterbodies as ORWs.

WDNR Stream Typing

On March 1, 2006, the WDNR implemented a new statewide water typing system. Although the maps used by the WDNR are new, the existing Forest Practices rule (WAC 222-16-031) was used to define water types. The new classification types are described below.

- Type S Water – Includes all waters, within their ordinary high-water mark (OHWM), inventoried as “shoreline of the state” under the RCW Chapter 90.58 and the rules promulgated pursuant to RCW Chapter 90.58, but not including those waters’ associated wetlands as defined in RCW Chapter 90.58.
- Type F Water – Includes segments of natural waters that are not classified as Type S Water and have a high fish, wildlife, or human use.
- Type N (Np or Ns) Water – Includes segments of natural waters within the bankfull width of defined channels that are not classified as Type S or F Waters, and which are perennial (Np) or seasonal (Ns) waters of nonfish-bearing streams.
- Type U Water – Because most stream typing for the state was done with photos, any streams or drainages showing up on the photos that have not yet been designated because field evaluation is still pending are listed as Type U. After the completion of field evaluations, most Type U Waters are designated as Type Ns Waters.

The waterbodies impacted by the proposed pipeline route are designated, in descending order of prevalence, as follows: 15 Type N Waters, 7 Type S Waters, 6 Type F Waters, and 1 Type U Water.

Section 303(d) List

Section 303(d) of the CWA requires that states periodically prepare a list of all surface waters in the state for which beneficial uses, such as for drinking, recreation, aquatic habitat, and industrial use are impaired by pollutants. This list is prepared by the WDE and typically provided biennially to the EPA as required under section 305(b) of the CWA. The surface waters are classified according to the most beneficial existing and potential future uses of the waterbody and to provide protection for a variety of uses. Water quality is classified as impaired if it exceeds the state-designated TMDL for various pollutants such as fecal coliform, temperature, pH, and dissolved oxygen-consuming compounds. A TMDL specifies the maximum amount of a pollutant that a waterbody can receive and still meet the intended or designated water quality use standards. The current section 303(d) list for Washington is the 2002/2004 list, which simply lists impaired waters and does not further categorize other waters in the state. The 2002/2004 list is the most recent list that was approved by the EPA.

Table 4.3.2-1 summarizes the section 303(d)-listed waterbodies in Washington and their status relative to each list, including the water quality parameters that are considered impaired in each waterbody. Seven waterbodies crossed by the portion of the proposed pipeline route in Washington are listed as section 303(d) waterbodies. The portion of the Columbia River in the vicinity of the proposed project is listed for temperature variations and mercury and arsenic levels outside of the water quality standards. Cameron Creek, Abernathy Creek, Germany Creek, Tributary 5 to Coal Creek, Coal Creek, and Ostrander Creek are listed for temperature variations outside the water quality standards. A discussion of the potential impacts on waterbodies that would be crossed by the proposed pipeline route is provided in section 4.3.2.4.

TABLE 4.3.2-1			
Summary of Section 303(d)-Listed Waterbodies Crossed by the Bradwood Landing Project in Washington			
Waterbody Name	MP	2002/2004 Section 303(d) Listed Impairments	Proposed Crossing Method
Columbia River	19.0 - 19.6	Temperature, Mercury, Arsenic	HDD
Cameron Creek	20.6	Temperature	HDD
Abernathy Creek	21.1	Temperature	HDD
Germany Creek	22.4	Temperature	HDD
Tributary 5 to Coal Creek	27.5	Temperature	Bore
Coal Creek	28.0	Temperature	HDD
Ostrander Creek	36.2	Temperature	Bore
Source: WDE, 2005b			

Designated Shorelines

As discussed in section 1.3.11, the Shoreline Management Act requires cities and counties to develop SMPs that regulate development along larger streams, lakes, and marine waters. The areas regulated include lands within 200 feet of a shoreline. The general management designations for shorelines in the state include: Natural, Rural and/or Conservancy, Aquatic, High-intensity, Urban Conservancy, and Shoreline Residential. Individual cities and counties may have slightly modified designations. A summary of the designated shorelines that would be affected by the proposed pipeline is provided in table 4.3.2-2.

TABLE 4.3.2-2			
Designated Shorelines Crossed by the Bradwood Landing Project in Washington ^a			
Waterbody Name	MP	Shoreline Designation	Proposed Crossing Method
Columbia River	19.0 - 19.6	Conservancy & Urban	HDD
Cameron Creek	20.6	Conservancy	HDD
Abernathy Creek	21.1	Conservancy	HDD
Germany Creek	22.4	Conservancy	HDD
Coal Creek	28.0	Conservancy	HDD
Cowlitz River	34.3	Conservancy & Urban	HDD
Ostrander Creek	36.2	Rural or No Designation	Bore
^a Designated as a stream/river constituting shorelines of the state per the Shoreline Management Act (Chapter 173-18 WAC).			

Seven waterbodies crossed in Cowlitz County are designated as streams/rivers constituting shorelines of the state per the Shoreline Management Act. Based on a review of Cowlitz County's SMP, the shorelines of five of these waterbodies are designated as "Conservancy" (Columbia River, Cameron Creek, Abernathy Creek, Germany Creek, and Coal Creek), one is designated as "Urban" (Cowlitz River), and one as "Rural" (Ostrander Creek). Utilities including gas pipelines are permitted within the Conservancy, Urban, and Rural Districts (Cowlitz County, 1977).

Critical Areas Ordinance

As discussed in section 1.3.11, the Growth Management Act requires local governments to identify and protect critical areas, including frequently flooded areas. Frequently flooded areas include, at a minimum, the 100-year floodplain designations of FEMA and the National Flood Insurance Program

(Washington State Department of Community, Trade, and Economic Development, 2003). Floodplain permits are issued wherever a pipeline crosses a mapped floodplain, which is referred to as a Special Flood Hazard Area on the FEMA maps. In some instances, the floodplain permit is administered through the Frequently Flooded Areas Section of the Critical Areas Ordinance, while in others it may be separate from the critical areas ordinance and governed by a stand-alone flood chapter of the county code. In Cowlitz County, development within designated frequently flooded areas is subject to the Cowlitz County Floodplain Management Ordinance (Chapter 16.25 CCC). Development is defined as a construction project involving property improvement or a change of physical character within the site and the act of using land for building or extractive purposes. Placement of a pipeline is included in this definition. A review of the Cowlitz County FEMA Flood Zone maps indicates that that pipeline would cross frequently flooded areas at the Columbia River (MP 19.6), Germany Creek (MP 22.4), Cowlitz River (MP 34.3), Tributary to Ostrander Creek (MP 35.0), and Ostrander Creek (MP 36.2).

4.3.2.2 Waterway for LNG Marine Traffic

Existing Surface Water Resources

As described in section 2.1.2, the waterway for LNG marine traffic associated with the Bradwood Landing Project extends from the territorial seas boundary to the proposed LNG terminal site at CRM 38 on the Columbia River. The Columbia River Basin is bound by the Rocky Mountain system on the east and north, the Cascade Range on the west, and the Great Basin on the south. Including upland areas, the total area of this drainage basin is 258,000 square miles. Waterways and lakes in the Columbia River Basin account for approximately 3,000 square miles, of which 2,500 square miles are within the United States.

The majority of the precipitation in the Columbia River Basin is in the mountainous areas during the winter season in the form of snow. These deep snowpacks provide significant runoff during spring snowmelt, with approximately 60 percent of the natural runoff occurring in May, June, and July. Due to this seasonal fluctuation in runoff, streams within this basin have low flows during the winter months and sustained, high flows during the spring and early summer.

The Columbia River begins at Columbia Lake in the Canadian Selkirk Mountains. It crosses the Canada-United States border near Spokane and is joined by the Snake River in central Washington. It continues to flow for approximately 1,214 miles before entering the Pacific Ocean near Astoria, Oregon. Average runoff at the mouth of the Columbia is about 275,000 cfs (COE, 2002). The Columbia River is tidally influenced, but considered freshwater because the extent of significant saltwater intrusion is generally limited to the lower reach of the river, where the salinity level ranges from 32 parts per thousand at the mouth of the river to 1 part per thousand at CRM 30, which is about 8 miles downstream of the proposed Bradwood Landing LNG terminal site (COE, 1999).

Temperature in the lower Columbia River is at risk from changes in the flow regime created by the federal dam system and from changes associated with global warming. Natural sediment loads have been decreased by the storage of fine sediment behind the dams. The dams have also significantly altered the natural hydrology of the Lower Columbia River by flattening out the peak flows during winter and spring and contributing to lower water levels during the summer and fall when water is withheld behind the dams. Chemical contamination (e.g., PCBs) and excess nutrient loading are issues in the lower Columbia River generally.

The lower Columbia River displays appropriate wetted width to maximum depth ratio. Stream banks are in relatively good and stable condition, with riparian vegetation present at most locations.

However, dikes and bank armoring with riprap have dramatically reduced the floodplain connectivity. This condition is exacerbated by the lack of significant flooding since the construction of upstream dams.

Parts of the Columbia River have been dredged periodically for more than 128 years to allow ships and barges carrying cargo to reach ports along the river. The mainstem of the river recently underwent channel deepening by the COE as part of the Columbia River Channel Improvement Project. As a result of the COE's dredging project, the main channel depth increased from 40 to 43 feet from the mouth of the river to the City of Portland.

Past the mouth of the Columbia River, the waterway extends 12 nautical miles across the continental shelf of the Pacific Ocean. The run off of the Columbia River is one of the largest in the United States, discharging approximately 244 billion cubic meters per year (at 275,000 cfs) (Federal Columbia River Power System, 2001). The coastal waters off northern Oregon and southern Washington are highly influenced by this freshwater run off (DeRobertis et al., 2005). Where the Columbia River meets the Pacific Ocean, a freshwater plume develops offshore. This plume is influenced by the mixed semi-diurnal tides, and therefore it is a transient feature (Morgan et al., 2005). Average sea temperatures from 1984 to 2001 ranged between a maximum of 59 °F and a low of 48 °F (NOAA, National Data Buoy Center, 2005).

Impacts and Mitigation

Dredging of the Ship Berth and Maneuvering Area

Impacts and mitigation associated with construction and maintenance dredging of the ship berth and maneuvering area are described in detail in section 4.3.2.3. Water quality impacts associated with dredging are expected to be temporary and minor.

Shoreline Erosion and Propeller Wash from LNG Carriers and Tugs

Propeller wash from LNG carriers associated with the project, as well as ship wakes breaking on shore could cause increased erosion along the shoreline and resuspend the eroded material within the water column. Shoreline erosion is discussed in more detail in sections 4.1.2.3, 4.1.3.3, and 4.5.2.1. During operation of the proposed LNG terminal, propeller wash and wakes from LNG carriers and tugs could temporarily increase suspended sediments and turbidity within the ship berth and maneuvering area and along the LNG carrier transit route. As a vessel navigates through a waterway, it generates hydraulic disturbances in the form of waves and currents, mainly drawdown, return current, slope supply currents, wash waves, and jet wash (Wolter and Arlinghaus, 2003). These activities have the potential to resuspend, and subsequently redeposit, sediments, resulting in impacts similar to those for dredging. Impacts associated with propeller wash would occur more frequently than dredging because as many as 125 LNG carriers may unload their cargos at the LNG terminal annually. Given the regular vessel traffic along the Columbia River, regular maintenance dredging of the navigation channel, the proposed location of the LNG terminal adjacent to the navigation channel, and the relatively coarse particles that make up the sediments at the ship berth and maneuvering area, we do not anticipate that propeller wash from LNG carriers and tugs would result in a significant degradation of water quality in the Columbia River.

Ballast Water and Ship Engine Cooling

Because the LNG carriers would be fully loaded when arriving at the proposed terminal, no ballast water would be discharged into the Columbia River. However, as the LNG cargo is unloaded, a carrier would take on water to maintain trim and stability and for cooling engines while docked at the

terminal. Potential impacts on water quality and aquatic resources due to ballast water intake and engine cooling water appropriations and discharges are discussed in sections 4.3.2.3 and 4.5.2.1, respectively.

Release of LNG or Fuel

In the unlikely event that LNG is spilled into the water from an accidental or intentional breach of an LNG carrier during transit, the cryogenic liquid would vaporize rapidly upon contact with the warm air and water. Being less dense than water, LNG would float on the surface before vaporizing. Because LNG is not soluble in water and would completely vaporize shortly after being spilled, the LNG could not mix with or contaminate the water.

Fuel (e.g., diesel) used for vessel propulsion or auxiliary/emergency generators on an LNG carrier could potentially spill or leak. However, fuel on each carrier is protected by the vessel's double hull. Furthermore, each LNG carrier would maintain a *Shipboard Oil Pollution Emergency Plan* (SOPEP) as required by international convention. The SOPEP would comply with MARPOL [marine pollution] 73/78 Consolidated Edition 2002 Annex 1 Regulation 26, which requires every oil tanker of 150 tons gross and above, and every vessel of 400 tons gross and above to carry an approved SOPEP. All LNG carriers would also be required to comply with state spill prevention and contingency plans, including the applicable requirements in Chapter 317-40 of the WAC – Bunkering Operations.

4.3.2.3 LNG Terminal

Existing Surface Water Resources

Two waterbodies within the Columbia River Basin would be affected by construction of the LNG terminal, the Columbia River and Hunt Creek. Existing conditions within these waterbodies are discussed below. Based on the wetland and other waters delineation report prepared for the project, nine small streams are located within the proposed 100-foot-wide construction corridor for the power line (URS, 2006c). These streams are intermittent; however, because most of the streams are fed, at least in part, by springs and seeps, they likely contain flows for much of the year. The majority of these streams eventually flow northwest from the proposed power line corridor to the Columbia River via Hunt Creek.

Columbia River

Columbia River water near the proposed LNG terminal site contains low concentrations of total dissolved solids (typically 80 to 100 mg/L), nitrates, carbonates, phosphates, and metals. Dissolved oxygen concentrations are usually close to saturation and turbidity levels are moderate. Typical total suspended solids (TSS) concentrations are 12 to 30 mg/L. Water temperatures are cool most of the year but can rise to 73 °F in the summer.

Currently, the water quality of the Columbia River is considered “marginally healthy” (COE, 2003). The segment of the Columbia River that would be impacted by the proposed project is an anadromous coldwater and warmwater fishery. It is designated as EFH for coho and Chinook salmon by the NMFS, as critical habitat for 12 salmonid evolutionary significant units (ESU) or distinct population segments (DPS) by the NMFS, and as Aquatic Natural or Aquatic Conservation areas by Clatsop County. The LNG terminal site location is also included in the Lower Columbia River Estuary, which belongs to the EPA's National Estuary Program. The EPA is working in coordination with the states of Idaho, Oregon, and Washington as well as the Columbia Basin Tribes to reduce pollutant loads within the river and to meet federal water quality standards.

Hunt Creek

The lower reaches of Hunt Creek are located immediately adjacent to the proposed LNG terminal site. The lower reach of Hunt Creek begins where an approximately 40-foot-high waterfall descends to the Columbia River floodplain and is characterized by low gradient meanders, tidally influenced backwater ponds, and freshwater tidal estuary at its junction with the Columbia River. Bottom sediments appear to be alluvial fine silt/sand, with a short section of gravel-bottom pool-riffle sequences near the waterfall. Upstream of the waterfall, Hunt Creek is characterized by high-gradient riffle/pool complexes confined to a deeply incised valley.

The water quality of Hunt Creek is not currently listed as either water quality limited or impaired by the ODEQ, due in part to the intact canopy and lack of recent disturbances. There is some sedimentation in the stream and evidence of turbidity during high flows, but the stream also contains a sizable proportion of clean gravels. Chemical contamination and excess nutrient loading are not a problem in the watershed.

Although Hunt Creek is designated a coldwater residential recreational fishery, angling is not currently permitted. Hunt Creek provides habitat for resident coldwater fish species, such as coastal cutthroat trout, and has been designated as EFH for coho and Chinook salmon and as critical habitat for federally listed salmonids (see section 4.6.2.2). Hunt Creek has been designated as Essential Salmonid Habitat by the ODFW.

Stormwater runoff from Clifton Road generally flows into a series of roadside ditches along the eastern side of Clifton Road. From the roadside channels, runoff flows west under Clifton Road via culverts, where it outfalls and sheet flows (or infiltrates) over dense native riparian vegetation towards Hunt Creek. Generally, the roadside ditches combine with streams conveying runoff from the upland areas along Clifton Road. A perennial stream is located east of the Highway 30 and Clifton Road intersection that conveys runoff from the southern portion of Clifton Road towards Hunt Creek. Based on a wetland/waterway survey conducted by NorthernStar in August 2006, 19 individual roadside ditches were identified along the 2.4-mile stretch of Clifton Road from Highway 30 to Bradwood Road. Table 4.3.2-3 summarizes the discharge locations along Clifton Road, along with the approximate milepost location (MP 0.0 represents the intersection of Highway 30 and Clifton Road).

TABLE 4.3.2-3			
Stormwater Runoff Discharge Locations from Clifton Road			
MP	Type of Discharge	MP	Type of Discharge
0.3	Stream	1.4	Stream/culvert
0.3	Stream	1.5	Stream/culvert

Construction Impacts and Mitigation

Activities associated with construction of the LNG terminal that could affect surface water resources include dredging of the ship berth and maneuvering area, dredged material placement, water

appropriation and discharge, stormwater runoff, electric power line, modifications to access roads and the Hunt Creek Bridge replacement, railroad realignment, and accidental spills or leaks of hazardous materials.

Dredging of the Ship Berth and Maneuvering Area

The primary impact of the project on surface water quality would result from using a hydraulic cutterhead dredge to remove approximately 700,000 cubic yards of material from the proposed ship berth and maneuvering area. Details of NorthernStar's proposed dredging are described in section 2.4.1.2. The effects of dredging on hydraulics in the Clifton Channel and main channel of the Columbia River are described in the discussion of NorthernStar's hydraulic and sediment transport modeling presented in section 4.2.2.2.

Dredging would result in a temporary increase in suspended solids in the water around the dredged area and the subsequent settling of the suspended particles, or sedimentation. The suspended sediment would temporarily reduce light penetration and could lower the rate of photosynthesis and aquatic productivity of the area. The introduction of sediment could also increase the amount of organic material and/or nutrients in the affected areas, which could lead to an increase in biological oxygen demand. This could reduce dissolved oxygen levels or cause a release of chemical constituents, such as metals, PCBs, pesticides, or PAHs, if present in the sediments. NorthernStar collected and tested sediment samples from the proposed dredge area to evaluate the quality and characteristics of the sediments that would be disturbed during construction of the project. As discussed in section 4.2.2.2, samples were collected in accordance with a SAP that was approved by the COE, EPA, and ODEQ through the RMT.

NorthernStar contracted WEST to conduct a hydrodynamic and sediment transport assessment for the dredging of the ship berth and maneuvering area (WEST, 2006). The assessment indicates that the proposed cutterhead dredge would spill approximately 0.5 percent of dredged materials. The total volume of material to be dredged for the berthing area and turning basin was estimated at 700,000 cubic yards. Based upon 0.5 percent spillage, the project would spill about 3,500 cubic yards of sediment during dredging activities. Based on their modeling, WEST concluded that the maximum sediment concentration would occur within 10 feet of the cutterhead.

Sediment spilled during dredging would create a plume of suspended sediment, reducing in-water visibility through increased turbidity. The size and duration of the sediment plume is highly dependent upon the grain size of the material being dredged. SWCA conducted a sediment analysis of the material which would be dredged as part of the proposed project. Within the dredge footprint, the substrate is almost exclusively sand, with very low silt and clay component (SWCA, 2006). Sand settles rapidly in the water column. Modeling by WEST shows that only particles smaller than 0.4 mm diameter are likely to be transported to areas outside the dredge footprint, while larger particles would settle within 10 feet from the cutterhead dredge. WEST's hydrodynamic model predicts that project-related suspended sediment loads would not exceed 1 mg/L at the dredge site and would diminish to 0.1 mg/L before reaching either Tenasillahe Island or Hunt Creek. By comparison, the typical TSS concentrations described above ranged between 12 and 30 mg/L and background levels of TSS measured in the field were on the order of 10 mg/L. Therefore, even assuming a considerable level of uncertainty in any of the model parameters, the impacts of the dredging operation would be very small and confined to an area immediately surrounding the proposed facility.

Background levels of turbidity in the Columbia River range from 3 to 10 NTUs. The WEST study demonstrates that turbidity plumes from dredging for the Bradwood Landing Project would return to within 1 NTU of background levels within 1 minute after suspension (WEST, 2006).

Dredging and all other in-water work in the Columbia River would be done during the in-water work window of November 1 to February 28. Additional information regarding impacts associated with dredging activities on sediment transport, aquatic resources, and special status species are provided in sections 4.2.2.2, 4.5.2.1, and 4.6.2.2, respectively.

Dredged Material Placement

As described in section 2.4.1.1, NorthernStar proposes to place up to 700,000 cubic yards of dredged material on the LNG terminal site to raise the base of the LNG terminal site to an elevation of 20 to 25 feet NAVD 88. As a result of the added fill, approximately 856,607 square feet (19.7 acres) of the LNG terminal site, including areas associated with Bradwood Road and Hunt Creek Bridge, that are currently below the 100-year floodplain would be raised above the 100-year floodplain. Before dredged material placement, a perimeter berm would be constructed around the area receiving dredged materials, forming a basin into which the dredged material would be placed. After fish and other aquatic life have been removed from the log pond (see section 4.5.2.1), the channel connecting the log pond to the Columbia River would be filled to complete the perimeter berm and isolate the pond from the river.⁶

As it is deposited on site, the water would separate from the dredged materials. Based on the relatively high permeability of the existing soils at the site and the dredged materials to be applied, infiltration rates are expected to be greater than the rate at which water would be applied during dredging. Therefore, NorthernStar anticipates that all of the water would percolate into the sandy soil at the site. However, during rainfall events, where the infiltration capacity of the soil may be more limited, the log pond would serve as a temporary holding area for excess water that would be generated. The pond would have approximately 50,000 cubic yards of storage volume, assuming a full depth of 20 feet. It is likely that water may continually be present that would reduce the capacity. Water from the dredged materials would not be allowed to overtop the perimeter berm and discharge to the river untreated.

Although it is expected that most of the water that accumulates in the pond would percolate into the ground, the log pond would be equipped with an overflow structure. The overflow structure would allow clarified water in excess of the storage capacity of the pond to drain to the Columbia River, and would be designed to have sufficient capacity to transport large volumes of water to the river through a temporary outfall discharge. This discharge would be located below the surface of the river a minimum of 20 feet from the shoreline. The residence time of any water that accumulates in the pond would be such that sediment would settle to the bottom of the pond and would not discharge to the river through the overflow structure. This water would not be expected to carry a high silt load because almost all the dredged material would be coarse and medium sand (see section 4.2.2.2).

Oregon's water quality standards require that discharges not increase the turbidity of river water more than 10 percent above background concentration. It is expected that this standard would be met at the point of discharge or outside a mixing zone that extends no more than 10 feet from the outfall.

Given the infiltration rate of the soils on site and the capacity of the holding pond for additional storage, NorthernStar expects discharge from the overflow structure to be very intermittent and only during periods of extremely high rainfall in conjunction with dredge material application. Water conveyed with the dredge material, as it is deposited on site, would separate fairly rapidly given the relative large grain size associated with the dredge material. It is anticipated that any water that would overflow would be low in sediment and of equal quality as Columbia River water.

⁶ NorthernStar included its *Work Area Isolation and Fish Salvage Plan* as part of its JPA. NorthernStar filed its JPA with the FERC on November 22, 2006, and filed revisions to the JPA on April 5, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

The overflow structure is expected to be a stand pipe-type system with a downturned elbow that would allow discharge of water that has had the greatest amount of time to allow for separation and settlement of any particulates. The log pond itself would be the last area to be filled on site, during which the stand pipe would either be removed or sealed in place.

In its May 11, 2007 letter to the FERC, the NMFS asked us to explain why the log pond could not be filled with existing dredged material stored at the western end of the LNG terminal site where no infrastructure except the stormwater treatment and infiltration gallery (which appears could be moved eastward) is proposed. The NMFS stated that such a modification would appear to minimize the volume of fill needed, reduce the terminal footprint, and provide the opportunity for some on-site wetland restoration. In response, all of the existing dredged material currently stored on the site would first be graded as the initial step in raising the site grade to an elevation of 20 to 25 feet NAVD. Additional fill would be supplied from the material dredged from the ship berth and maneuvering basin. Because the log pond would be used as a dewatering basin to collect water drained from the dredged sediments, it would be the last area filled. The western end of the site would be used during construction as a staging and storage area. NorthernStar has already aggressively minimized the layout during operation (see section 3.1.6.2) and no changes to the location of the stormwater treatment system could be made that would significantly reduce the facility footprint.

The material that is dredged from the ship berth and maneuvering area that is not placed at the LNG terminal site would be placed at the Wahkiakum County Sand Pit site, located at the northern end of Puget Island. This site currently includes a settling basin consisting of earthen fill levees designed to contain the dredged material and hold the return water while allowing sand and suspended sediment to settle. Weirs would be used to regulate the return of water to the river. Water returned to the river through weirs would be subject to applicable water quality standards, after dilution, at an appropriate point of compliance. Once the pipeline dredge deposits the material and the water is drained, the sand would be spread evenly around the holding area. The de-watered sand would then be distributed and graded by earthmoving equipment along the eroding shoreline on Puget Island and pushed into scour holes adjacent to the shoreline. These activities could potentially increase suspended sediments and turbidity in the vicinity of the dredged material placement site. A specific model has not been run to determine the anticipated turbidity levels resulting from placement of dredged materials at the Wahkiakum County Sand Pit site. However, given the coarse grain size of the sediments, the materials are expected to rapidly settle out of the water and water quality impacts would be similar to that at the LNG terminal site during dredging operations (see *Dredging of the Ship Berth and Maneuvering Area*). Therefore, water quality impacts are expected to be temporary and minor.

Water Appropriation and Discharge

NorthernStar has applied for a temporary water use permit from the ODWR for the maximum quantity of water that would be needed during construction of the proposed LNG terminal. As indicated in table 4.3.1-1, water would be appropriated from the Columbia River for multiple uses during construction of the LNG terminal, including:

- up to 60 million gallons for testing of the LNG tanks; and
- 15 million gallons for soil compaction and ground improvements.

Figure 2.1.3-3 shows the proposed intake and discharge locations. No potable water intakes were identified within 3 miles downstream of the proposed LNG terminal, although several are located upstream. NorthernStar would obtain up to 60 million gallons of water from the Columbia River for hydrostatic testing of the LNG storage tanks. Testing of a single LNG storage tank would require 30 million gallons of water. NorthernStar plans to schedule construction activities to enable water used to

test the first tank to be reused to test the second tank, which would reduce the amount of water needed for hydrostatic testing of the tanks to 30 million gallons. However, if construction does not proceed as planned, the two tanks may need to be tested at different times, in which case, twice the amount of water would be needed. Hydrostatic testing of the LNG tanks is expected to take approximately 1 month per tank; however, the timing is dependent on the construction of the tanks themselves so a specific time that the activity would occur is not known yet. For additional information on water appropriations for construction of the LNG terminal, see sections 4.3.1.3 and 4.5.2.1.

River water used for hydrostatic testing of the tanks would be filtered before use to remove suspended solids and tested for bacteria. If bacteria concentrations are high enough to cause corrosion of the 9 percent nickel steel tanks and stainless steel surfaces within the tanks, then a sodium hypochlorite solution would be used to chlorinate the water before hydrostatic testing. After use, the hydrostatic test water from the tanks would be discharged to the Columbia River through a temporary outfall extending approximately 300 feet offshore. If the water has been chlorinated, it would be tested for chlorine residual before discharge. If chlorine residual exceeds applicable effluent limits, the spent hydrostatic test water would be dechlorinated using a sodium bisulfite solution before discharge. The sodium bisulfite dose rate would be established based on the level of chlorine residual. Sodium bisulfite solution would be introduced into the discharge pipeline close to the storage tanks, and the dechlorination reaction would be complete before discharging the water to the river.

It is expected that the hydrostatic test water from the tanks would not need treatment, other than possible dechlorination, before it is discharged to the river. However, all batches of hydrostatic test water would be sampled and analyzed before discharge to determine whether they contain any substances that would not meet Oregon's water quality standards. If such substances are detected, the hydrostatic test water would be treated as necessary to enable safe discharge to the river. Assuming that the hydrostatic test water does not need treatment beyond dechlorination, it is expected that it would meet Oregon's ambient water quality standards at the point of discharge.

Water used for hydrostatic testing of piping at the LNG terminal (approximately 1.5 million gallons) may be discharged to the Columbia River through a temporary outfall. Similar to water used to hydrostatically test the storage tanks, it is expected that the hydrostatic test water from the piping would not need to be treated before discharge to the river. However, all batches of water used for hydrostatic testing of piping would be sampled, analyzed, and treated, if necessary, to enable safe discharge to the river.

During construction, NorthernStar would also appropriate approximately 15 million gallons of water from the Columbia River for soil compaction and ground improvements. This work would occur over a period of 3 to 4 months and likely between the months of July and December. The water would not be discharged to surface waters, and is discussed further in section 4.3.1.3.

No water would be either appropriated from or discharged to Hunt Creek.

Stormwater Runoff

Stormwater runoff during construction of the LNG terminal could potentially affect water quality in both the Columbia River and Hunt Creek. To minimize these potential affects, NorthernStar has developed a terminal ESC Plan that contains BMPs for management of stormwater during construction. Additional information on NorthernStar's terminal ESC Plan is provided in section 4.3.1.3.

Electric Power Line

The proposed electric power line route and associated 100-foot-wide right-of-way would impact 0.6 acre of habitat within nine waterbodies. Based on the information provided by NorthernStar, these waterbodies are relatively narrow and occur in steep areas. In some cases, these waterbodies are intermittent and/or flow underground for portions of their length.

The impacts of power line construction on the minor intermittent and perennial streams along the route would generally be localized and short term. It is expected that the power line would span the tributaries so as to avoid impacts on surface waters. However, if required, clearing trees and vegetation adjacent to these waterbodies would have the greatest effect on water quality, including potential increases in water temperature. Sediments could be resuspended by in-stream construction activities or by erosion of cleared stream banks and riparian areas. Turbidity resulting from the resuspended sediments could reduce light penetration and the corresponding photosynthetic oxygen production. Resuspension of deposited organic material and inorganic sediments could cause an increase in consumption of biological and chemical oxygen, decreasing available dissolved oxygen. However, the potential impacts on surface waters would be minimized through the implementation of BMPs by PacifiCorp and the requirements of state and local permits and approvals.

Access Roads and Hunt Creek Bridge Replacement

To accommodate vehicle traffic associated with construction and operation of the project, Clifton Road would need to be paved and widened to 28 feet, including shoulders (based on engineering drawings submitted by NorthernStar). In addition, a drainage ditch would be constructed on the west side of the road. Impacts on Hunt Creek would be minimized through the implementation of NorthernStar's terminal ESC plan and our Plan and Procedures. To this end, NorthernStar has indicated that construction on the eastern side of the road (adjacent to Hunt Creek) would be completed in a manner that would not allow any sediment to wash into Hunt Creek. Because Hunt Creek has been designated as both EFH and critical habitat for federally listed salmonids, potential impacts on water quality due to construction of Clifton Road will be analyzed in additional detail in the revised BA and EFH Assessment.

As discussed in section 2.1.3.6, Bradwood Road enters the LNG terminal site from Clifton Road over a bridge that crosses Hunt Creek. Although most of the existing roadway is above the 100-year flood elevation (13.23 NAVD), the portions below the 100-year flood elevation would be raised. Following construction, the elevation of Bradwood Road would vary, but would generally exceed 14 NAVD. Bradwood Road would also need to be paved and widened to 24 feet for use during construction and operation of the proposed project. Similarly, the existing bridge over Hunt Creek is not adequate to withstand the anticipated loadings associated with construction-related traffic and would be replaced with a 24-foot-wide bridge.

The new Hunt Creek Bridge would be built from four pre-cast concrete deck bulb T-girders. These would be supported on 12-inch-diameter concrete-filled steel piles that would be placed above the mean higher high water (MHHW) elevation and then vibrated into place. The new Hunt Creek Bridge deck would be 2.4 feet above the 100-year flood elevation. Each side of the bridge would be curbed and have curb-mount rails. Cast-in-place concrete aprons would be added at the ends of the bridge to match the existing grade. The bridge would be sloped to one side, and an additional 25 feet of extruded concrete curb would be constructed beyond the concrete apron on the downslope side of the bridge from both the west and the east. This curb is designed to guide stormwater to vegetated roadside areas before draining to Hunt Creek.

Bridge demolition, activities below the OHWM, and construction of over-water portions of the bridge would occur during the in-water work period for Columbia River tributaries between Big Creek and St. Helens of July 1 – September 15. NorthernStar would implement its terminal ESC Plan to avoid or minimize impacts on water quality during construction of the Hunt Creek Bridge (see Attachment B-1). In addition, NorthernStar would apply the following bridge demolition and construction BMPs:

- Existing pilings would be left in place unless they interfere with the proposed bridge. In-water work would be very limited, consisting of cutting off existing bridge piers and piles that would interfere with the new bridge.
- Excavation required for the installation of the concrete abutments would be conducted from up-bank, and would be minimized to the amount necessary to place the structure. NorthernStar does not expect placement of the abutments to result in any measurable turbidity during construction.
- A temporary erosion and sediment control plan would be developed prior to beginning any construction work. The plan would include erosion control methods to prevent silt or toxic material-laden water generated from any land-disturbed areas or construction equipment servicing areas from entering Hunt Creek. These methods may include silt fences, filter fabric, straw bales, dust suppression, temporary sediment ponds, check dams of pea gravel-filled burlap bags or other material, diversion dams with flexible drainage pipe outfalls and pumps as necessary to divert flows, a controlled construction entrance, and mulching of exposed areas upon completion.
- Equipment servicing and fueling would be conducted a minimum of 100 feet upland from Hunt Creek. Any heavy equipment operating over (or within) Hunt Creek would be inspected for lubrication or fuel leaks. Any leaks detected would be corrected prior to commencing work.
- During bridge demolition and construction work, water quality monitoring would be conducted at a point 100 feet downstream from the bridge. A baseline observation for water clarity would be taken at a point upstream from the work area past the prominent meander loop. The final location of the sites would be determined as a condition of the 1200-C permit issued by the ODEQ. NorthernStar would use a turbidity meter to determine turbidity levels at both the background site and the downstream monitoring site.
- In the event that turbidity at the downstream monitoring site exceeds a level approximately 10 percent above turbidity at the background site, work would stop until either the turbidity was cleared or it could be ascertained that the difference in turbidity levels was not due to construction activities.⁷ During periods of low turbidity, fluctuations of 10 percent could occur naturally due to complex interactions between Hunt Creek and the Columbia River.
- The areas where the demolition activity would involve bank-side disturbances would be revegetated with native vegetation that is typical to the area. Revegetation is described in detail in section 4.4.2.2.

⁷ Note that short-term exceedance of the 10 percent turbidity threshold is allowed for construction if all available BMPs have been used and the potential for exceedance is recognized in the section 401 Water Quality Certification for the Joint Permit issued by the ODEQ.

- During activities associated with paving of the Hunt Creek Bridge deck, NorthernStar would employ the following additional BMPs developed by the ODEQ:
 - Selection and deployment of oil-absorbing materials and pads as well as a complete spill kit for use in response to accidental discharges and/or spills of petroleum or chemical products.
 - Prevention of stormwater pollution through the proper disposal of waste, control of stormwater run on, and minimization of stormwater runoff.
 - Elimination of discharge litter and/or other discarded debris by providing appropriate, labeled, and accessible containers for solid waste disposal.

Improvements to Bradwood Road and the Hunt Creek Bridge could potentially increase turbidity and suspended sediment levels within Hunt Creek. However, turbidity associated with bridge construction is expected to be of very short duration and would be associated primarily with removing the supports from the old bridge that interfere with construction of the new bridge. Any turbidity that would develop would be minimized by implementation of the BMPs described above, very localized (e.g., within 50 to 100 feet of the bridge), and expected to clear within a tidal cycle or sooner. If the supports are cut above the water line, turbidity associated with their removal would be negligible. However, in its May 11, 2007 letter to the FERC, the NMFS raised concerns regarding the level of monitoring proposed at Hunt Creek during demolition and construction, and specifically the absence of an upstream (as opposed to merely a background) monitoring point. Hunt Creek is tidally influenced and contains high-quality habitat for federally listed salmonids. Therefore, in addition to placing its baseline monitoring site upstream from the proposed bridge replacement, **we recommend that:**

- **NorthernStar should conduct water quality monitoring at points both 100 feet downstream and 100 feet upstream from the Hunt Creek Bridge during demolition or construction activities. In the event that water clarity exceeds a level approximately 10 percent above the baseline observation at either monitoring point, work would cease until either the turbidity was cleared or it could be ascertained that the difference in turbidity levels was not due to construction activities.**

Railroad Line Realignment

During construction, the existing railroad line would be rerouted and would parallel Hunt Creek for approximately 2,000 feet. For most of this length, the creek and the edge of the railroad right-of-way would be between 50 and 400 feet apart. Hunt Creek would not be directly affected by railroad construction; however, for about 50 feet, the edge of the railroad right-of-way and Hunt Creek would be less than 50 feet apart. The railroad tracks would occupy approximately 22 feet at the center of the 100-foot-wide railroad right-of-way, and would have approximately 5-foot-wide ditches maintained along both sides of the railroad tracks. To minimize potential impacts on Hunt Creek, a 2-foot-high berm of earth covered with native grass would be constructed between the Hunt Creek oxbow and the railroad tracks. The berm would extend for 100 feet centered on the apex of the oxbow. In addition, NorthernStar would use concrete railroad ties in place of treated railroad ties within 100 feet of any wetland or waterbody, including Hunt Creek. NorthernStar's terminal ESC Plan describes measures that would be taken to prevent railroad bed ballast, other construction materials, or eroded soil from entering Hunt Creek during construction.

Accidental Spills and/or Leaks of Hazardous Materials

Water quality in the Columbia River and Hunt Creek could also be adversely affected by a spill, leak, or other release of hazardous materials during construction activities. NorthernStar would minimize potential impacts associated with spills or leaks of hazardous materials during construction by implementing the spill prevention and response procedures in its terminal ESC Plan. Among these procedures are paving operation controls developed by the ODEQ that NorthernStar would implement during construction of the Hunt Creek Bridge. These include proper disposal of waste, controlling stormwater run on, and minimizing stormwater runoff.

The only area where uncured concrete would potentially come in contact with surface water is during construction of the wharf. During dock construction, expandable foam would be used to seal the forms and ensure that uncured concrete is fully contained. The forms used for concrete work would be built taller than the necessary height to ensure that uncured concrete (and any rainwater that collects on top) could not discharge to surface water. Any water generated as the result of concrete curing and/or rainwater collected in the concrete forms would be pumped to the terminal for treatment as necessary to meet water quality standards.

Operation Impacts and Mitigation

Operation of the LNG terminal could potentially impact water resources through stormwater runoff, maintenance dredging of the ship berth and maneuvering area, shoreline erosion, propeller wash from LNG carriers and tugs, water appropriations and discharges, and accidental spills or leaks of hazardous materials during operation of the LNG terminal.

Stormwater Runoff

During operation of the proposed project, there is potential for stormwater runoff to affect water quality in the Columbia River and Hunt Creek. As part of its Removal-Fill Permit application to the ODSL and COE, NorthernStar has developed a *Stormwater Management Plan for Removal/Fill Permit Applications* for the LNG terminal.⁸ Given the limited guidelines for stormwater facility design in Clatsop County, NorthernStar referenced the City of Portland's Stormwater Management Manual for calculating stormwater runoff volumes, flow rates, and for initial facility design (City of Portland, 2004). Current site and soil characteristics promote the use of infiltration for disposal of stormwater generated from impervious surfaces. Based on final grade elevation, NorthernStar divided the proposed LNG terminal facility into three primary drainage basins. The drainage basins would be maintained regularly to remove any accumulated debris and sediment that would reduce their effectiveness. Because stormwater would be managed on site via infiltration, there would be no overflow into either Hunt Creek or the Columbia River.

Relative to stormwater runoff from Clifton Road, the total existing impervious surface associated with Clifton Road is approximately 5.8 acres, assuming an average width of 20 feet along its 2.4-mile length. Widening of the paved roadway to 24 feet plus 2-foot-wide shoulders on either side (see section 2.4.1.1) is expected to result in an increase of approximately 2.3 acres of impervious surface. Additional culverts and drainage ditches would be installed to improve the drainage. Permanent erosion and sediment control for the road will be analyzed in additional detail in the revised BA and EFH Assessment.

⁸ NorthernStar included its *Stormwater Management Plan for Removal/Fill Permit Applications* as part of its JPA. NorthernStar filed its JPA with the FERC on November 22, 2006, and filed revisions to the JPA on April 5, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

Improvements to Bradwood Road and the Hunt Creek Bridge would result in slight increases to the total impervious surface. The existing site access road varies from 15 to 19.5 feet wide and the existing bridge ranges from 20 to 21.5 feet wide. The existing road is graveled, with an asphalt layer underneath approximately 75 percent of the roadway. The total impervious surface (including gravel area) associated with the existing road and bridge is about 0.4 acre. Current drainage from the existing roadway is directed onto adjacent heavily vegetated roadside areas (the site is relatively flat along Bradwood Road) and primarily infiltrates into the sandy substrate. The existing bridge discharges to Hunt Creek because the deck is made of timber members with gaps between them.

As described in section 2.4.1.1, the proposed roadway and bridge alignment generally follows the existing alignment, except immediately west of the Hunt Creek Bridge, where the road swings wider onto the old second bridge alignment. The proposed roadway and bridge would be surfaced in asphalt. The total impervious surface associated with the proposed modifications to Bradwood Road and the new Hunt Creek Bridge is approximately 0.6 acre.

Of the total modified roadway and new bridge area, approximately 0.3 acre would be area associated with the existing roadway and bridge alignment. Approximately 0.1 acre of area associated with the existing roadway and bridge alignment at the east end would be removed and revegetated as a result of the new, shorter proposed roadway and bridge alignment. Therefore, the total impervious surface associated with the proposed roadway and bridge alignment is 0.6 acre, where 0.3 acre is redeveloped impervious surface and 0.3 acre is new impervious surface. Accounting for the existing impervious surface that would be removed, the net new impervious surface is 0.2 acre.

Although the new Hunt Creek Bridge would increase the total impervious surface, it would have a solid surface decking and curbing that would prevent untreated stormwater from discharging directly into Hunt Creek. Existing topography and vegetation would be used for stormwater management as much as possible. Stormwater would discharge from the end of the curb extensions into small rock flow spreader structures before flowing through vegetation. On the east side of the bridge, the over-ground flow distance between the discharge site and Hunt Creek is about 45 feet, vegetation is dense, and the slope is relatively gentle. In addition, during site restoration, there would be an opportunity to add additional native vegetation next to the road edge to improve dissipation of stormwater. On the west side of the bridge, the curb would discharge to the former road bed, which has an over-ground flow distance to Hunt Creek of about 30 feet (see figure 2.1.3-2). This area would be revegetated with native species after construction. A bioswale placed on the west side of the bridge would be designed to increase this flow distance and provide storage necessary to promote infiltration. Any roadside swale used for erosion and sediment control during construction-phase activities could be retained to provide treatment via infiltration, and control overflow to the relatively steeper slope leading to Hunt Creek.

Based on the design parameters outlined in NorthernStar's SWMP, the discharge sites described above would be adequate to provide water quality treatment for at least the 2-year 24-hour storm. The impervious area that would drain to the curb ends is approximately 10,125 square feet, with half of this drainage going to each end. The 2-year 24-hour storm, approximately 3.8 inches, would produce about 1,600 cubic feet of precipitation over the bridge and adjacent curbed area. Assuming that 98 percent of that precipitation is runoff, and using a conservative (i.e., low) infiltration rate of 0.3 feet per hour, about 225 square feet would be required on each side of the bridge to fully infiltrate such a storm. However, as described by the NMFS (2003a), no detention is needed because flow in Hunt Creek discharges almost immediately into the Columbia River, which is large compared to the runoff expected from with the small amount of impervious surface area associated with the bridge. Sediment discharged from the road would not be expected to markedly alter infiltration rates, as it would not be enough to damage established woody vegetation.

The proposed roadway would continue to direct stormwater into heavily vegetated roadside areas where the sandy substrate would allow rapid infiltration. Existing contours indicate that the area associated with the extended portion of the roadway (which runs 170 feet farther east than the existing alignment) currently drains towards a ditch that eventually discharges to Hunt Creek. Drainage of the roadway extension is expected to follow the same flow patterns and discharge location as the existing bridge. In summary, no significant change in the drainage area discharging to Hunt Creek is expected as a result of the improvements to Bradwood Road and the Hunt Creek Bridge.

In its May 11, 2007 letter to the FERC, the NMFS inquired why inundation would not threaten bridge integrity. In response, NorthernStar filed additional information stating that the bridge design calls for the use of pre-cast concrete sections that cannot float. Therefore, regardless of water stage, the weight of the bridge would cause it to remain on the abutments. Debris at the site has been of negligible consequence for the existing bridge, which is many decades old, made of wood, has in-water supports, and experiences twice-daily inundation (the bottom of the deck gets wet) from Columbia River high tide backwater effects. This bridge survived the 1996-1997 floods with no such damage. Because the new bridge would have no in-water supports, it would be able to convey debris much more easily. The new bridge would also be higher than at least the existing 10-year flow water surface elevation. In addition, flow velocities in Hunt Creek during floods are typically very low, as the downstream portion of the creek is backwatered from high water on the Columbia River. Therefore, lateral forces from debris loads necessary to displace the bridge are highly unlikely to develop.

Maintenance Dredging of the Ship Berth and Maneuvering Area

NorthernStar estimates about 80,000 cubic yards of material would be removed from the ship berth and maneuvering area approximately every 2 to 4 years as part of maintenance dredging. Material from maintenance dredging would be deposited at the Wahkiakum County Sand Pit site located at the northern end of Puget Island or some other approved dredge disposal site. If placement is at the Wahkiakum County Sand Pit site, NorthernStar anticipates using a cutterhead section dredge with a 30-inch discharge pipe and a 4,950 HP pump, which would be consistent with the size used to complete the initial dredging of the ship berth and maneuvering area. NorthernStar is currently proposing to use the Port of Portland's dredge "Oregon" for maintenance dredging. The operation rate of this dredge is 1,500 cubic yards per hour (WEST, 2006). Therefore, with time for initiation and set up, it is expected that maintenance dredging would occur over a 2-week time frame. If a different dredge material disposal site is used, a clamshell/barge or hopper dredge would be necessary and the dredging time frame may vary depending on the disposal location.

A specific model has not been run to determine the anticipated turbidity levels resulting from placement of dredged materials at the Wahkiakum County Sand Pit site or other approved disposal site. However, given the coarse grain size of the sediments, the materials are expected to rapidly settle out of the water and water quality impacts would be similar to that at the LNG terminal site during dredging operations (see *Construction Impacts and Mitigation, Dredging of the Ship Berth and Maneuvering Area*). Therefore, water quality impacts are expected to be temporary and minor.

Water Appropriation and Discharge

As indicated in table 4.3.1-1, water would be appropriated from and discharged to the Columbia River for multiple uses during operation of the LNG terminal, including ballast water and ship engine cooling, testing of the fire suppression system, and condensate water from the SCVs. Potential impacts on water quality from these appropriations and discharges are discussed below.

Ballast Water and Ship Engine Cooling

LNG carriers unloading at the LNG terminal would appropriate water from the Columbia River for ballast and ship engine cooling. LNG carriers would not discharge any ballast or onboard wastewater during off-loading operations at the LNG terminal site. As described in section 2.1.1.5, NorthernStar has stated that it would construct and install a system capable of delivering filtered river water to the LNG carriers. This system would use a screened water intake located at the wharf (see figure 2.1.3-3) that would minimize the entrainment and impingement of juvenile fish. NorthernStar's design plans require that LNG carriers be retrofitted to utilize the system and to cycle engine cooling water into the ballast tanks to avoid the discharge of warm water to the Columbia River.

We recommended in the draft EIS that NorthernStar prepare a plan to ensure that only LNG carriers that have been retrofitted to use the screened water supply system at the wharf are allowed to unload cargo at the Bradwood Landing LNG terminal. The FERC received numerous comments on the draft EIS in support of the recommendation. We also received comments questioning the engineering feasibility of the screened water supply system to accommodate various ship designs, the engineering feasibility of the necessary retrofitting to allow LNG carriers to utilize the system, and the feasibility of enforcement. In filings to the FERC on March 24 and April 9, 2008, NorthernStar stated that it could not guarantee that all LNG carriers that arrive at the terminal would have the necessary retrofitting in place to allow the use of the screened water supply system. NorthernStar described that its proposed project could require the use of various types of shipping contracts, such that some LNG carriers calling on the LNG terminal would not use the terminal on a regular basis (e.g., spot market contracts, short term contracts, and the occasional use of replacement carriers for long-term contracts). Because LNG carriers could only be retrofitted to use the screened water supply system when in dry-dock (something that happens only twice over a five year period), or during new construction, NorthernStar stated that some carriers using the LNG terminal would not be retrofitted to use NorthernStar's screened water supply system.

NorthernStar has stated that it would continue to offer incentive-based contractual agreements for vessels to accommodate the screened water supply system, but that performance standards should be used to address regulatory gaps and bolster the mitigation potential of the LNG terminal's onsite water system. NorthernStar proposes to develop a performance standard for the temperature of all cooling water discharges at the wharf and a performance standard for entrainment of juvenile fish at the wharf. Both performance standards would have a monitoring component. To date, we have not been provided any information on these potential performance standards.

To minimize impacts on aquatic resources, we are recommending in section 4.5.2.1 that NorthernStar adhere to the condition requiring LNG carriers to be retrofitted, as recommended in the draft EIS, or develop an alternative system meeting the same standard that does not require vessel retrofitting. We recognize that an alternative system design may not eliminate cooling water discharge. Therefore, we have included a discussion below of potential impacts on water quality in the case that LNG carriers arriving at the LNG terminal have not been retrofitted to use the proposed screened water intake system and therefore, discharge cooling water in a traditional mode of ship operation.

NorthernStar estimates that LNG carriers unloading cargo at the terminal would appropriate between 20 and 50 million gallons of water for ballast and ship engine cooling, combined. NorthernStar has not provided a break down of the water requirements for engine cooling and ballast separately, which is necessary to determine the potential volume of water discharge from LNG carriers and the volume of water that would be removed from the system. Therefore, table 4.3.2-4 presents the typical intakes and discharges associated with LNG carrier ballast and engine cooling that were provided in the final EIS for the Broadwater LNG Project (FERC, 2008). The estimates are for 145,000 m³ and 250,000 m³ capacity LNG carriers, and thus represent an approximation since NorthernStar expects that LNG carriers ranging

in capacity from 100,000 m³ to 200,000 m³ would service its terminal. We note that the Coast Guard would restrict the size of the LNG carriers operating on the Columbia River to a maximum cargo size of 148,000 m³ until additional risk analyses addressing larger vessels have been completed.

TABLE 4.3.2-4		
LNG Carrier Intakes and Discharges while Berthed at the LNG Terminal Wharf		
Type of Intake or Discharge	Volume of Intake (million gallons)	Volume of Discharge (million gallons)
Ballast Water		
145,000 m ³ LNG carrier (steam powered)	13.2	Not expected
250,000 m ³ LNG carrier (diesel powered)	25.6	Not expected
Cooling Water		
145,000 m ³ LNG carrier (steam powered)	57.2	57.2
250,000 m ³ LNG carrier (diesel powered)	18.6	18.6

As with other large cargo ships, LNG carriers would take on ballast water to maintain stability and trim as cargo is off-loaded. The amount of ballast water required varies according to vessel size, weather conditions, cargo load, water salinity, sea state, and the ship master's discretion. A typical 145,000 m³ LNG carrier would require approximately 13.2 million gallons of ballast water, which also would support routine operational needs such as generation of freshwater and fire suppression systems. This is comparable to ballast requirements of the average large oil tanker operating on the lower Columbia River, which may take on between 8.3 and 13.8 million gallons of water for ballast while at port. In the future, larger diesel powered LNG carriers (250,000 m³ capacity) would require nearly twice as much ballast water (25.6 million gallons) as the smaller steam powered LNG carriers. There are currently 218 LNG carriers operating world-wide, ranging in capacity from 1,100 m³ to 154,000 m³, and nearly all of them are steam powered. Approximately 15 percent of LNG carriers under construction will be diesel powered.

Ballast water obtained from the Columbia River is transported out of the river when the carrier departs. Based on the normal flow rate used by WEST in the Hydrodynamic and Sediment Transport Assessment (210,000 cfs), about 136 billion gallons of water per day would pass the LNG terminal. Thus, the amount of water removed by a typical LNG carrier for ballast would be less than 0.01 percent of the total volume of water present at any given time. The impact of removing this water volume from the lower Columbia River system would be minor. Furthermore, we do not expect the reduction in flow to significantly affect aquatic habitats, discussed further in section 4.5.2.1.

In addition to ballast water, LNG carriers would appropriate and discharge water for ship engine cooling while docked at the wharf. Based on the estimates provided in the final EIS for the Broadwater, LNG Project (FERC, 2008), a steam powered LNG carrier would intake and discharge a total of about 57.2 million gallons of water while berthed at the proposed LNG terminal (less than 24 hours). The next generation of LNG carriers (larger and diesel powered) are estimated to require approximately 18.6 million gallons of cooling water while berthed at the proposed LNG terminal, about one-third of the cooling water needed for steam powered carriers. Because none of these diesel powered LNG carriers have been constructed, all information regarding water use is an approximation.

LNG carriers would discharge cooling water throughout the transit route from the territorial seas to the proposed LNG terminal location. Although various types of LNG carriers could offload at the proposed site, the greatest cooling water discharge would be associated with steam powered carriers. Based on the estimates provided in the final EIS for the Broadwater LNG Project (FERC, 2008), the cooling water discharged from a 150,000 m³ steam powered LNG carrier could initially be 19.4 °F higher than ambient water temperatures. Because the cooling water intake would be at ambient temperature,

which is seasonally dependent (ranging between 42 °F and 68 °F in Astoria, Oregon), the water discharge temperature would be expected to range between about 61 °F and 87 °F at the immediate discharge location. Impacts associated with cooling water discharge from the larger diesel powered LNG carriers would be expected to be comparable to or less than those described above for steam powered LNG carriers.

As described above (see *Oregon Water Quality, Section 303(d) List* and *Washington Water Quality, Section 303(d) List*), the Columbia River is currently listed as impaired for water temperature. LNG carriers that have not been retrofitted to use the screened water intake system could temporarily exacerbate elevated water temperatures in the immediate vicinity of the wharf. NorthernStar has indicated that it would develop a performance standard for the temperature of all cooling water discharges at the wharf, which would have a monitoring component. The impacts of LNG carrier water discharges at the terminal would be mitigated to a less than significant level after detailed modeling and the establishment of appropriate performance standards and a detailed set of operating procedures that would reasonably assure that the standards could be met.

The cooling water for the LNG carriers may be injected with a low dose of biocide (expected to be sodium hypochlorite for LNG carriers). This is standard practice in the shipping industry to prevent the growth of marine organisms. This residual chlorine concentration is not expected to significantly affect water quality, due to the low concentration of sodium hypochlorite that may be present in the discharge. Mixing upon discharge would occur rapidly due to the volume of water in Columbia River and mixing by the tides and currents.

LNG carrier operations and any resulting impacts on water quality would be comparable to typical shipping traffic, and would need to comply with international and U.S. shipping regulations. Impacts on water quality from current and future LNG carriers would be minor, but a recurring and incremental impact on the water resources of the lower Columbia River. The potential impacts on aquatic resources as a result of LNG carrier water intakes and discharges are discussed further in section 4.5.2.1. To ensure development of performance standards that minimize impacts on water quality from LNG carrier water withdrawals and discharges at the wharf, **we recommend that:**

- **Within 30 days after the issuance of the final EIS, NorthernStar should develop the following performance standards for water discharges at the Bradwood Landing terminal wharf:**
 - a. **standards for water temperature impacts due to discharging cooling water from LNG carriers into the Columbia River that should include modeling to determine the temporal and spatial extent of impacts on water quality and salmonids; and**
 - b. **standards for impacts from biocide use that should include specific forms and concentrations of biocide that would be used, the anticipated concentration of biocide at the discharge location, and modeling to determine the temporal and spatial extent of toxicity to aquatic resources.**

Testing of the Fire Suppression System

About 13.7 million gallons of water would be withdrawn from the Columbia River every year to test the fire suppression system at the LNG terminal. Although the fire suppression system would only be used in emergencies, water would be required weekly for system testing. After completion of the weekly test, the test water would be returned directly to the Columbia River without any other use. The quality of the water discharged from the fire suppression system would be essentially the same as the quality of

water withdrawn from the river. Fire suppression water would be obtained from the Columbia River at a rate of 4,400 gpm for 1 hour each week using the permanent water intake and pump station on the dock as shown on figure 2.1.3-3. It would be returned to the Columbia River at rate up to 4,400 gpm via outlets on the fire suppression system piping on the north end of the dock approximately 300 feet from the shoreline. The return of fire suppression water to the Columbia River would have no adverse effects on water quality and would meet ambient water quality standards at the point of discharge. Because the discharge outlets would be located over 300 feet from the shoreline in an area with an approximate water depth of 42 feet, the potential for scour would be negligible and diffusers would not be necessary.

Condensate Water from the SCVs

Water is produced as a by-product in the LNG vaporization process proposed by NorthernStar. Under the proposed design, the SCVs would generate up to 160 gpm (0.23 mgd) of condensate water. Because this water condensate is typically acidic, it must be neutralized with alkaline chemicals before discharge. Table 4.3.2-5 shows the results of chemical analysis of neutralized condensate from two existing LNG terminals. Condensate from the proposed terminal would be expected to have similar characteristics. NorthernStar proposes to discharge the excess SCV water directly to the Columbia River under an NPDES permit following pH adjustment. Sampling and analysis of the SCV discharge would be carried out in accordance with the requirements of the NPDES permit issued by the ODEQ. The ODEQ began the NPDES permit process on October 18, 2007 when the COE published its Public Notice for Permit Application associated with the JPA and JARPA, which included the ODEQ's 401 Water Quality Certification Public Notice.

The SCV condensate water would be discharged using an outfall/diffuser system mounted about 15 feet below the water surface in water approximately 25 feet deep (MLLW), with its main alignment parallel to shore at a distance of about 150 feet from shore on the main pipe trestle. This location would take advantage of better water circulation in the mainstem of the Columbia River. The proposed diffuser would be 40 feet long, 31/32 inch in diameter, and would have nine ports. The outfall/diffuser system would be designed to rapidly mix the discharged condensate with river water.

The pH of the water bath in an SCV is typically maintained at 5.6 standard units and the temperature of the discharge water would be 68 °F. Before discharge, the pH of the SCV discharge water would be increased in a neutralization tank. An allowable discharge pH would be established during the NPDES permit review process. The average water temperature in the Columbia River measured in Astoria between December 2005 and 2006 was 54.4 °F, ranging between 42 °F and 68 °F, depending on the season (NOAA National Oceanographic Data Center, 2006). On average, the SCV discharge water would generally be warmer than the ambient water temperatures but would not exceed a maximum of 68 °F, which is the ODEQ's lower Columbia River water quality criterion for temperature (Coast & Harbor Engineering, Inc. (CHE), 2007). Furthermore, the Columbia River flows at a rate of more than 45,000,000 gpm more than 95 percent of the time. Given the volume of discharge (160 gpm) in relation to the volume of flow, we anticipate that water temperatures near the outfall would rapidly return to ambient conditions.

In its May 11, 2007 letter to the FERC, the NMFS questioned whether LNG could be used to cool the SCV condensate water to more closely approximate the temperature of the Columbia River water. In response, NorthernStar explained that such a heat exchange process, while theoretically possible, would not be economically feasible or practicable due to the extreme temperature difference between the LNG (at -260 °F) and the condensate (at 68 °F).

TABLE 4.3.2-5		
Constituent Data for Vaporizer Condensate		
Parameter	Sample Site 1 Concentration (mg/L unless specified)	Sample Site 2 Concentration (mg/L unless specified)

As part of the NPDES permit application process, CHE modeled the mixing zone created by the SCV discharge using the CORMIX computer model (Jirka et al., 1996). The results were provided in a technical memorandum titled *Mixing Zone Analysis for Bradwood Landing Point Source Discharges – NorthernStar Natural Gas*, which was submitted by NorthernStar in response to our recommendation in the draft EIS.⁹ The goal of the analysis was to provide the approximate lateral extents of the acute and chronic mixing zones within which discharge concentrations and temperatures may be above the State of Oregon acute and chronic water quality criteria. The modeling was based on conservative assumptions (i.e., very low flow conditions with an ambient current velocity of 0.0 ft/s and maximum rather than average constituent concentrations).

Prior to mixing, the SCV condensate discharge would meet the acute and chronic water quality criteria for temperature and all modeled constituents except chromium VI, copper, and silver. Of these, the highest level of acute mixing would be required for chromium VI (16.9 times) and the highest level of chronic mixing would be required for silver (150 times). Therefore, these constituents determine the size of the acute and chronic mixing zones, which were calculated by the model to extend 2 feet and 100 feet

⁹ NorthernStar filed its *Mixing Zone Analysis for Bradwood Landing Point Source Discharges – NorthernStar Natural Gas* with the FERC on October 15, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

from the discharge, respectively. In other words, for some constituents under the conservative conditions modeled, concentrations within 2 feet of the discharge would be above acute water quality standards and concentrations within 100 feet of the discharge would be above chronic water standards. Total chromium data from an existing LNG facility was used for the mixing zone analysis but was conservatively assumed to be chromium VI, although chromium VI was not specifically detected. Also it is important to note that the input data used for the silver was based on a laboratory detection limit, because no silver was actually detected in the SCV discharge.

Accidental Spills or Leaks of Hazardous Materials

Spills, leaks, or other releases of hazardous materials during operation of the proposed project could also adversely affect surface water quality. As discussed above, a 5-foot-high perimeter berm would surround the portion of the LNG terminal containing the LNG storage tanks and vaporization units. The berm would provide containment in the unlikely event of a tank rupture. Within the bermed area, any equipment that has the potential to leak oil and grease would be isolated from the rest of the site with curbing so any leakage can be contained and cleaned up. In the unlikely event that LNG is spilled into the water from the terminal, the cryogenic liquid would vaporize rapidly upon contact with the warm air and water. Being less dense than water, LNG would float on the surface before vaporizing. Because LNG is not soluble in water and would completely vaporize shortly after being spilled, the LNG could not mix with or contaminate the water.

4.3.2.4 Pipeline Facilities

Existing Surface Water Resources

The proposed pipeline route would impact 94 waterbodies in Oregon and Washington. Of these, 65 are located in Oregon and 28 are located in Washington; the remaining waterbody is the Columbia River, which is located in both states. These waterbodies and their proposed crossing methods are listed in table 4.3.2-6. In addition, levees are located adjacent to several waterbodies in Oregon.

Between MPs 0.0 and 19.4, the proposed pipeline would be located in the State of Oregon. Based on information from the ODEQ, there are currently no state waters listed as ORWs as defined under the anti-degradation statutes of the State of Oregon. Any waters that meet or exceed all the listed beneficial uses for that waterbody are considered High Quality Waters. Thus, any waterbodies along the Oregon portion of the pipeline route that are not listed as impaired waters are High Quality Waters. Also, waterbodies containing federally listed threatened and endangered species or their designated critical habitat can be qualified as sensitive surface waters (see section 4.6.2.3). Along the portion of the proposed pipeline route in Oregon, four waterbodies qualify as sensitive surface waters, including the Westport Slough (MP 5.2), Westport Slough/Midland Canal (MP 10.0), Clatskanie River (MP 13.2), and Columbia River (MP 19.0). NorthernStar would use the HDD construction method at each of these crossings to avoid impacts on waterbody banks and beds. These waterbodies, and the federally listed species occurring in them, are discussed in section 4.6.2.3.

TABLE 4.3.2-6

Waterbodies Impacted by the Bradwood Landing Project

^a Protected substrates describe areas that have been protected from flooding, often referring to agricultural areas.

^b NMFS, Northwest Fisheries Science Center, 2005

F Fishbearing.

N Nonfish-bearing streams, may be perennial or intermittent.

WDNR, 2006

S Shoreline, fish-bearing streams.

F Waters that have a high fish, wildlife, or human use, and are not classified as Type S.

N Nonfish-bearing streams, may be perennial or intermittent.

U Undetermined.

^c Approximate width.

^d Not crossed by proposed centerline. No crossing method proposed.

^e Tributary 5 to Coal Creek is designated as a nonfish-bearing stream by the WDNR; however, this waterbody is known to contain coho salmon.

Between MPs 19.4 and 36.3, the proposed pipeline would be located in Cowlitz County, Washington. No ORWs are currently listed in Cowlitz County. Waterbodies that contain threatened and endangered species or their designated critical habitat can also be qualified as sensitive surface waters. Nine sensitive surface waters occur along the portion of the proposed route in Washington, including: Columbia River (MP 19.6), Cameron Creek (MP 20.6), Abernathy Creek (MP 21.1), Germany Creek (MP 22.4), Tributary 5 to Coal Creek (MP 27.5), Coal Creek (MP 28.0), Cowlitz River (MP 34.3), Tributary 1 to Ostrander Creek (MP 35.0), and Ostrander Creek (MP 36.2). As is the case in sensitive waterbodies in Oregon, NorthernStar would use the HDD or bore method to cross each of these sensitive surface waters. These waterbodies and the federally listed species known to occur in them are further discussed in section 4.6.2.3.

Source Water Assessment reports and maps from the ODEQ show that there are five drinking water protection areas (DWPA) in the general vicinity of the Oregon portion of the pipeline route. The Westport Water Association, the City of Clatskanie, and the Midland Water Association DWPAs are all upstream from the pipeline route and would not be affected by the project construction or operation. However, the proposed pipeline route would cross the Wauna Mill and PGE Beaver Power Plant DWPAs.

Wauna Mill has a water intake on the Columbia River. This water supply serves the mill and about 750 citizens with public water. The intake on the Columbia River is within 3 miles of the proposed pipeline route but more than 10 miles downstream of the proposed crossing of the Columbia River. The DWPA for this water intake stretches along the Columbia River east from Wauna to Port Westward. The pipeline route would also cross Driscoll and Westport Sloughs, whose confluences with the Columbia River are each less than 3 miles upstream from the Wauna Mill intake. Because NorthernStar plans to cross these waterbodies using the HDD method, construction of the proposed pipeline would not be expected to affect this DWPA.

The Beaver Power Plant also has a water intake on the Columbia River. The proposed pipeline route would cross the Columbia River just downstream of the intake structure, but the proposed right-of-way would pass through a small portion of the Beaver Power Plant DWPA along the Columbia River. The construction and operation of the pipeline should not affect the DWPA.

Impacts and Mitigation

Activities associated with the proposed pipeline route that could affect surface water resources include waterbody crossings, water appropriation and discharge associated with hydrostatic testing, stormwater runoff, accidental spills or leaks of hazardous materials, and operation and maintenance of the pipeline. These activities and their potential impacts on surface waters are discussed below.

Waterbody and Levee Crossings

To minimize impacts on surface waters, NorthernStar would adhere to the protective measures specified in its *Waterbody and Wetland Construction and Mitigation Procedures Plan*, pipeline ESC Plan for construction in Oregon and SWPPP for construction in Washington, and our Procedures. The method used for installing the pipeline across waterbodies is determined, at least in part, by the size of the waterbody (i.e., minor, intermediate, or major) and on the condition of each waterbody at the time of crossing. Minor waterbodies include all waterbodies with a width less than or equal to 10 feet at the water's edge at the time of crossing, intermediate waterbodies include all waterbodies with a width greater than 10 feet but less than or equal to 100 feet at the water's edge at the time of crossing, and major waterbodies include all waterbodies with a width greater than 100 feet at the water's edge at the time of crossing.

Several waterbody crossings would also include levees that are located adjacent to the waterbody. Levees are owned and managed by local levee districts that are recognized by the state. If construction activities occur within the levee district's easement, the district will review the construction plans and send them to the COE for a structural integrity review. The COE has technical guidance in place regarding the construction of pipelines under levees that would be taken into account in its structural integrity permit. NorthernStar would complete construction of its pipeline across levees in accordance with the local levee district's construction easement and the COE's technical guidance.

All waterbody crossings that involve open trenching would occur during established in-water work windows. HDD or conventional bores may be performed outside of the in-water work times as they do not involve construction below the OHWM or MHHW.

In general, NorthernStar intends to segregate and store topsoil separately during pipeline construction, except in saturated wetlands. However, topsoil segregation takes up more construction right-of-way and, near a waterbody, it may require clearing more riparian vegetation or driving back and forth in a riparian area. To avoid these additional adverse impacts, NorthernStar may not segregate topsoil within 50 feet of waterbody crossings, depending on the vegetation and land use present.

NorthernStar proposes to install the pipeline across up to 18 waterbodies using the HDD method (see table 4.3.2-3). As shown on figure 2.4.2-4, the HDD method eliminates the need to excavate a trench through the stream or river channel, and would minimize or eliminate the impacts associated with sedimentation and turbidity from the standard wet open-cut methods of pipeline construction. NorthernStar has agreed to follow our Procedures, which require submittal of a plan prior to construction containing site-specific construction diagrams showing the location of mud pits, pipe assembly areas, and all areas to be disturbed or cleared for construction. In addition, the Procedures require a contingency plan for an alternative crossing method at each HDD location in the event that the HDD method is unsuccessful. Such alternative methods may require permits and approvals, which would be needed in advance to avoid significant construction delays. NorthernStar has indicated in its *HDD Contingency Plan* that it would have approved alternative crossing methods for implementation in the event of HDD borehole failure.¹⁰

A loss of drilling mud to the waterbody during the HDD procedure (referred to as a "frac-out") would introduce sediment into the waterbody. Frac-outs occur when the path of least resistance for the drilling mud is to the surface, rather than back along the borehole to the entry or exit pits. This may happen if a fault or fracture zone is encountered, or if the driller fails to keep the borehole clear of cuttings. Drilling mud, which is composed of approximately 5 percent bentonite clay and 95 percent water, may frac-out to the ground surface or into the waterbody being crossed. The highest potential for a frac-out typically occurs at the beginning or the end of the HDD where the separation between the borehole and ground surface is the least. NorthernStar's *HDD Contingency Plan* provides procedures and measures to be taken during an inadvertent release of drilling mud. NorthernStar would station the necessary equipment and supplies to respond to a release of drilling mud upon discovery of loss of drilling fluid. At the time of a release of drilling mud, NorthernStar would stop drilling immediately, contain drilling fluids, and notify appropriate agencies. Appropriate resource experts, such as fisheries biologists and wetland scientists would be on site to monitor resources and effects of the release.

In its December 19, 2007 letter providing comments on the draft EIS, the EPA recommended that the *HDD Contingency Plan* include mitigation measures for frac-outs to water, marsh, and uplands.

¹⁰ NorthernStar included its revised *HDD Contingency Plan* (Frac-out Plan) as Attachment B of its *Waterbody and Wetland Construction and Mitigation Procedures Plan*. NorthernStar filed this plan with the FERC on December 21, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

Although NorthernStar's *HDD Contingency Plan* provides mitigation measures for frac-outs to waterbodies and wetlands, mitigation measures for frac-outs to uplands are not addressed. To assure that adequate protection is provided to uplands in the event of a frac-out, **we recommend that:**

- **NorthernStar should revise its *HDD Contingency Plan* to include mitigation measures for frac-outs to uplands. Prior to pipeline construction, the revised *HDD Contingency Plan* should be filed with the Secretary for the review and written approval of the Director of OEP.**

Geotechnical investigations were conducted at 13 proposed HDD waterbody crossing locations (URS, 2006b). The results indicated that the assessed HDD alignments were generally feasible from a geologic standpoint and presented little risk of frac-out. URS recommended additional investigation after project approval to refine the subsurface conditions beneath difficult geometries and/or sensitive watersheds prior to final HDD design. Also see our recommendation in section 4.1.4.3 regarding additional site-specific geotechnical studies that would be required.

NorthernStar is also proposing to use the conventional bore method for up to eight waterbody crossings (see table 4.3.2-3). The bore method is similar to the HDD method in that the pipeline is installed beneath a waterbody without disturbing the bed and bank of the waterbody. Boring requires the excavation of pits on each side of the feature. Potential impacts on water quality resulting from boring operations would be due to the relatively large work areas and continuous pumping in order to manage groundwater during pipeline installation. NorthernStar would implement the FERC staff's Procedures in order to minimize impacts on water quality. In addition, trench boxes or sheet piling may be used to support the pit walls and to help cut off groundwater inflows. Dewatering systems using deep wells or well points are frequently employed. The specific type of bore (e.g., jack and bore, slick bore, hammer bore) that would be utilized in a given area depends on the construction site characteristics, the type of soils present, and the contractor's familiarity with available methods.

In addition to using the HDD or bore methods for crossing waterbodies, NorthernStar also would use an open-cut technique for waterbody crossings. Clearing and grading of streambanks, in-stream trenching, backfilling, and trench dewatering could affect surface water quality through increased sedimentation, increased turbidity, decreased dissolved oxygen concentrations, and stream warming. Open-cut crossings would use a standard dry-trench method including either the dam and pump or flume method. As described in section 2.4.2.2, the dam and pump method is a dry-crossing technique that uses pumps to isolate water from the construction work area, thereby avoiding in-stream activities (see figure 2.4.2-3). The flume method is similar to the dam and pump method except that dams and flumes are used instead of pumps to move water across the construction work area (see figure 2.4.2-2). Use of these waterbody crossing methods in flowing streams would reduce exposure of waterbodies to erosion and sedimentation, and thus reduce the overall impact on the waterbody.

The impacts of the open-cut construction method on the minor intermittent and perennial streams along the pipeline routes would generally be localized and short term. Clearing, grading, and trenching within and adjacent to these streams would have the greatest effect on water quality. Clearing of trees, vegetation, and large woody debris (LWD) in and around streams could lead to an increase in water temperature. Sediments would be resuspended by in-stream construction activities or by erosion of cleared stream banks and riparian areas. Turbidity resulting from the resuspended sediments could reduce light penetration and the corresponding photosynthetic oxygen production. Resuspension of deposited organic material and inorganic sediments could cause an increase in consumption of biological and chemical oxygen, decreasing available dissolved oxygen. To minimize impacts on surface waters, NorthernStar would implement its *Waterbody and Wetland Construction and Mitigation Procedures Plan*, pipeline ESC Plan for Oregon and SWPPP for Washington, and our Procedures. The stream bed

substrate would be conserved at each crossing and restored. If additional material is needed, matching material would be used. Most in-stream work within minor waterbodies would be completed within 24 hours, and stabilization and restoration of the stream banks would begin within 24 hours of construction, or before returning flow to the waterbody for dry crossings. However, due to the importance of numerous waterbodies along the proposed route for federally listed species, **we recommend that:**

- **NorthernStar should continue to consult with the COE, NMFS, FWS, and other appropriate federal and state agencies to finalize its *Waterbody and Wetland Construction and Mitigation Procedures Plan*. The final plan should include the following:**
 - a. **a description of the specific methods of in-water habitat mitigation to be conducted;**
 - b. **measures to prevent the spread of invasive species due to construction activities within waterbodies and wetlands; and**
 - c. **procedures for monitoring the success of the revegetation and weed control efforts.**

The plan, including agency comments on the plan, should be filed with the Secretary for review and written approval by the Director of OEP prior to pipeline construction.

With the implementation of the proposed measures, impacts on water quality would be temporary and would be expected to return to preconstruction levels soon after the stream crossing is completed.

The seven waterbodies impacted in Cowlitz County designated as shorelines of the state would be crossed using either the HDD or bore method. As previously discussed, utilities including gas pipelines are permitted within the Conservancy, Urban, and Rural Districts (Cowlitz County, 1977); however, typically the county places the following restrictions on utilities in these districts:

- All utility systems shall be underground unless such undergrounding would not be feasible;
- Where utility systems occupy shoreline areas, clearing necessary for installation or maintenance shall be kept to the minimum width necessary to prevent interference by trees and other vegetation with the proposed transmission facilities; and
- Upon completion of installation of such utility systems or of any maintenance project that disrupts the environment, the disturbed area shall be regraded to compatibility with the natural terrain and replanted to prevent erosion and provide an attractive, harmonious vegetation cover.

NorthernStar's proposed pipeline facilities within shoreline areas in Cowlitz County would be located underground. At some waterbodies, use of the HDD or bore method (with bore pads set back from the OHWM and associated wetlands by at least 200 feet) would minimize vegetation clearing (see section 4.4.2.3). To reduce impacts on vegetation within the construction and permanent rights-of-way and improve revegetation potential for open-cut waterbody crossings, NorthernStar would implement its SWPPP and *Waterbody and Wetland Construction and Mitigation Procedures Plan* in Washington. Following construction, all work areas would be restored, seeded with conservation grasses (a mixture of grasses, legumes, and forbs), native plant species, or other standard erosion control/cover species, where

required, and allowed to naturally revegetate to preconstruction conditions. Additional information on operation and maintenance of the pipeline is provided below. For these reasons, it appears that the proposed pipeline segment through Cowlitz County would be consistent with the substantial development and conditional use provisions of the SMP.

Water Appropriation and Discharge Associated with Hydrostatic Testing

Following backfilling of the trench, the pipeline would be hydrostatically tested to ensure it is capable of safely operating at the design pressures. As indicated in table 4.3.1-1, approximately 9 million gallons of water would be required for hydrostatic testing of the proposed pipeline. In order to account for any water losses and make-up water, NorthernStar obtained a Limited Use License from the ODWR for approximately 9.5 million gallons of water. The water would be supplied via temporary piping connections or transported by tanker truck. Water temperature in the Columbia River would not be impacted from this diversion of water.

Water for project use would be acquired from the Columbia River at the location where the pipeline construction right-of-way meets the river on the Oregon side of the project. The method of diversion would be a single diesel-fired pump via an 8-inch-diameter intake hose equipped with a fish screen that complies with the NMFS screen design requirements. The maximum rate at which water would be diverted from the Columbia River for hydrostatic testing of the pipeline is 2,000 gpm.

NorthernStar anticipates that the completed pipeline would be tested in multiple segments, reusing the test water, including separate tests for each HDD pull section before and after being pulled into the borehole. Following each HDD hydrostatic test, the water would be collected and reused as water for the drilling mud or subsequent HDD hydrostatic test sites. Make-up water would be trucked from the Columbia River. At the completion of the last HDD testing cycle, which would probably be the Columbia River HDD, the final test water would be discharged to the ground at an upland site. Discharge rates may be up to 1,000 gpm and would be through a straw bale enclosure designed to reduce the discharge velocity in order to prevent erosion, and to filter the water to reduce turbidity. The discharge would have no direct overland contact with any waterbody. The water would be discharged at an upland location near the point of diversion to ensure a cross-watershed disposal would not occur. A general design for the straw bale enclosure is shown on figure 4.3.2-1. This design would be modified as appropriate to fit conditions specific to the discharge site.

Testing would not be required for the pipeline hydrostatic test water discharge as no contaminants (e.g., oil, grease, solvents,) are used in the construction procedures for the pipeline. The only addition to the water would be dirt and some scale from the pipe, which would be filtered out of the discharged water by the straw bale enclosure.

Stormwater Runoff

Stormwater runoff during construction of the proposed pipeline could affect surface water quality in the vicinity of the project. To minimize these potential effects, NorthernStar has developed a *Waterbody and Wetland Construction and Mitigation Procedures Plan*, a pipeline ESC Plan for Oregon, and SWPPP for Washington.

NOTE:
STAKES SECURING SILT FENCE BETWEEN
HAY BALES ARE NOT SHOWN FOR CLARITY

NOTES:

1. STRUCTURE SHALL BE PLACED ON A LEVEL WELL VEGETATED SITE SUCH THAT WATER WILL FLOW AWAY FROM STRUCTURE AND ANY WORK AREAS.
2. FLOW RATES THROUGH DISCHARGE AND DIFFUSER PIPE SHALL BE SUCH THAT STRUCTURE WILL NOT OVERFLOW.
3. A 30' x 30' RECTANGULAR STRUCTURE MAY BE SUBSTITUTED FOR THE CIRCULAR CONFIGURATION SHOWN.
4. DIMENSIONS SHOWN ARE THE MINIMUM ACCEPTABLE AND MAY BE VARIED DEPENDING UPON SPECIFIC LOCATION.

Figure 4.3.2-1
Bradwood Landing Project
Straw Bale Enclosure General Design

Accidental Spills or Leaks of Hazardous Materials

Surface water quality could also be adversely affected by a spill, leak, or other releases of hazardous materials during construction activities. NorthernStar would minimize potential impacts associated with spills or leaks of hazardous materials during construction by implementing spill avoidance and response procedures included in its pipeline ESC Plan, SWPPP, and *Waterbody and Wetland Construction and Mitigation Procedures Plan*.

Operation and Maintenance of the Pipeline

The proposed pipeline would be operated and continuously monitored by a remote control center to be located at the LNG terminal. Operational activities with the potential to impact water quality would be limited to maintenance of the permanent right-of-way and repair of the pipeline. To minimize impacts on water quality and riparian vegetation, NorthernStar would allow a riparian buffer at least 25 feet wide, as measured from the waterbody's MHW mark, to permanently revegetate with native plant species across the entire right-of-way after construction is completed. However, trees greater than 15 feet tall, or deep-rooted shrubs that could damage the pipeline's protective coating, obscure periodic surveillance, or interfere with potential repairs, would not be allowed to grow within 15 feet of the pipeline. The frequency of the vegetation maintenance would depend upon the vegetation growth rate. This ongoing maintenance may have a discountable effect on stream temperature where large trees are not allowed to establish, and may reduce localized cover.

Periodic inspections by pipeline personnel may identify soil erosion that may expose the pipe, stressed vegetation that may indicate a leak in the line, or other conditions that require preventive maintenance or repairs. Impacts on water quality due to pipeline maintenance would be similar to those described above for waterbody crossings and would be subject to additional state and federal permitting.

4.4 WETLANDS AND TERRESTRIAL VEGETATION

4.4.1 Wetlands

Wetlands are defined by the COE and the EPA as areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and under normal circumstances do support, a prevalence of wetland vegetation typically adapted for life in saturated soil conditions (Environmental Laboratory, 1987). Wetlands can be a source of substantial biodiversity and serve a variety of functions that include providing wildlife habitat, recreational opportunities, and flood control, as well as naturally improving water quality.

Wetlands in the project area are regulated at the federal, state, and local levels. On the federal level, the COE has authority under section 404 of the CWA to review and issue permits for activities that would result in the discharge of dredged or fill material into waters of the United States, including wetlands. Wetlands are also regulated at the state level by the ODSL and WDE, and at the local level by counties and some cities. For example, wetlands are considered critical areas and included in the Critical Areas Ordinance of Cowlitz County. Section 404 of the CWA requires that proposed dredge and fill activities be issued section 401 Water Quality Certification by the designated state agency, in this case the ODSL or WDE. The WDE also has authority to regulate wetlands under two state laws, the State Water Pollution Control Act and the Shoreline Management Act. The ODSL has authority to regulate wetlands under the Oregon Removal-Fill Law.

Wetlands within the project area were classified according to the Cowardin et al. (1979) system which classifies wetlands based on specific shared characteristics. Cowardin defines five systems: 1) the marine system includes open ocean and its associated high energy coastline; 2) the estuarine system includes semi-enclosed salt and brackish marshes, non-vegetated tidal shores, and brackish waters of coastal rivers and embayments; 3) the riverine system includes freshwater rivers and streams with flowing water; 4) the lacustrine system includes large open water fresh lakes and ponds; and 5) the palustrine system includes freshwater marshes, bogs, swamps, and shallow ponds. In the Cowardin system, wetlands are further defined by cover type. Emergent wetlands are characterized by erect, rooted, herbaceous hydrophytes. Emergent wetlands are often associated with waterbodies, such as lakes or rivers, and are characterized by intermittent and seasonal inundation. Scrub-shrub wetlands are dominated by woody vegetation, including shrubs and small trees generally less than 20 feet tall. Forested wetlands are dominated by woody vegetation that is at least 20 feet tall. Unconsolidated shores and bottoms are characterized by areas with less than 30 percent vegetative cover and at least 25 percent cover of particles smaller than stones.

4.4.1.1 Waterway for LNG Marine Traffic

Wetlands located along the waterway to the LNG terminal are shown on the maps included in Appendix C and wetlands within the Zones of Concern are shown on figure 4.4.1-1. Major aquatic habitat types in the upper estuary section of the Columbia River include estuarine tidal scrub-shrub and emergent wetlands, shallow water/flats, medium depth water, and deep water (LCFRB, 2004). Tidal scrub-shrub and emergent wetlands in this portion of the river typically occur between MHW and the line of non-aquatic vegetation. Tidal scrub-shrub consists of dense forest and shrub thickets, while emergent wetlands are most often found on floodplain margins and in backwater sloughs. Shallow water/flats are defined as being between elevations slightly above the MLLW to 6 feet below MLLW (LCFRB, 2004). Shallow water/flats often contain emergent vegetation where water levels are shallow and submerged aquatic vegetation such as Canadian waterweed (*Elodea canadensis*) in areas of deeper water. Medium depth water is between 6 and 18 feet below MLLW, while deep water is defined as 18 feet and deeper. Emergent vegetation is absent in medium and deep open water areas, with the river bottom providing rocky, sandy, or occasionally submerged aquatic vegetative habitats.

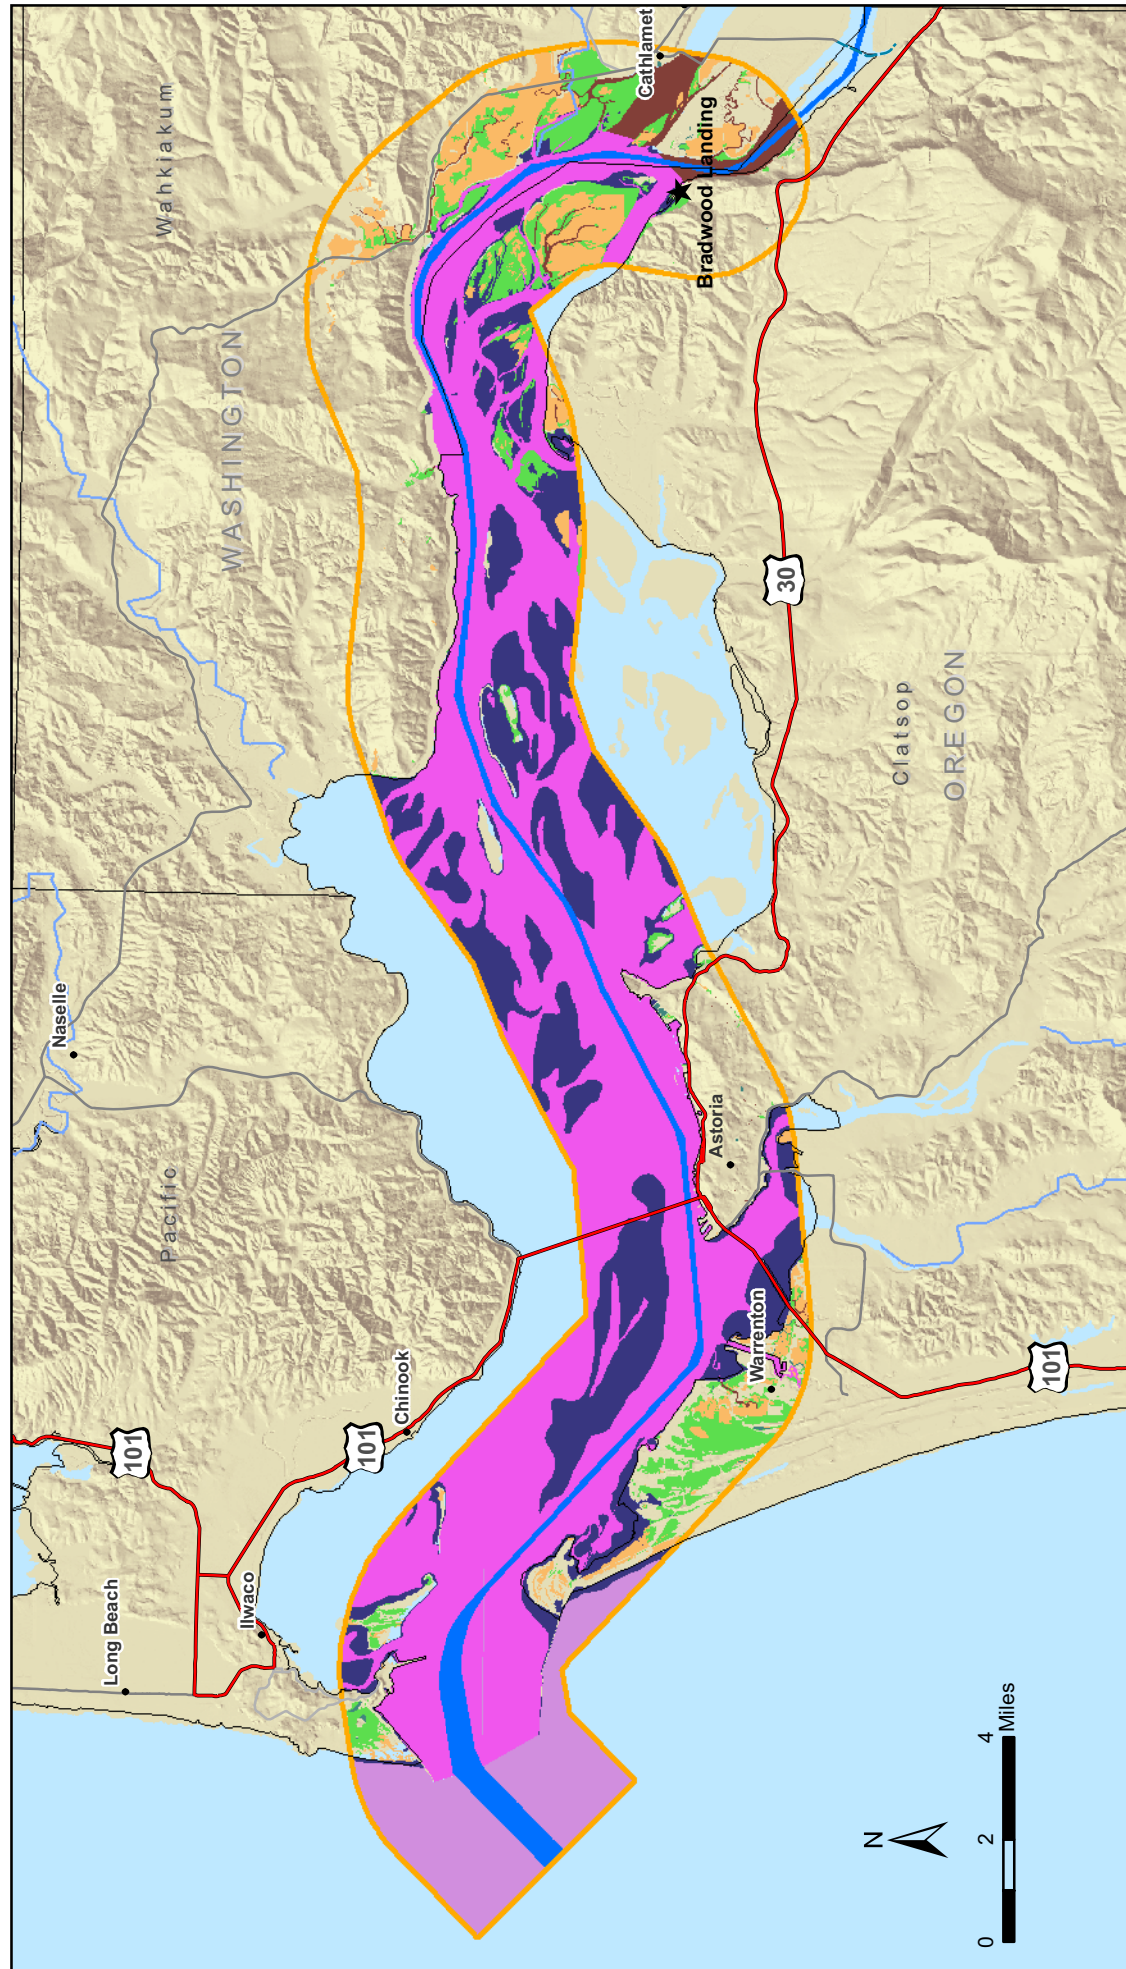

Figure 4.4.1-1
Bradwood Landing Project
 Wetland Areas in Zones of Concern

Data Source:
 Wetlands: U.S. Fish & Wildlife Service, National Wetlands
 Inventory/Date: Ranges from Oct. 1981 to present;

Estuarine scrub-shrub, estuarine emergent, palustrine scrub-shrub, and palustrine emergent wetlands are present along the waterway. Estuarine scrub-shrub wetlands are characterized by wetland-associated shrubs, including red-osier dogwood (*Cornus stolonifera*), Sitka willow (*Salix sitchensis*), and rose spiraea (*Spiraea douglasii*). Estuarine emergent wetlands are characterized by mudflats and shallow water areas that support emergent vegetation. Dominant vegetation includes Canadian waterweed and non-natives reed canary-grass (*Phalaris arundinacea*) and Himalayan blackberry (*Rubus discolor*). Palustrine scrub-shrub wetlands are primarily comprised of red-osier dogwood and Sitka willow. Palustrine emergent wetlands are of relatively low quality, with dominant vegetation consisting of reed canary-grass and other nonnative weedy species.

The wetlands located nearer to the navigation channel have some potential to be affected by vessel transit, although not measurably above baseline conditions due to the altered nature of much of the shoreline. That is, the depth of the navigation channel prevents wetland formation immediately adjacent to it and much of the steeper shoreline areas are armored, diked, or otherwise hardened. Furthermore, because of the sheer size of the Columbia estuary area (i.e., the width of the channel in the lower river), wave energy dissipates more before reaching shoreline areas. The wetlands are created and maintained by dynamic riverine and geomorphic processes and are more influenced by changes in river flow affecting water levels and adjacent land use practices than they are by industrial river traffic. Many, if not most, of the wetlands are located adjacent to very shallow water side channels and sloughs and around islands in the estuary, such that any vessel with steering problems would run aground of these shallows and sand shoals long before encountering fringe wetlands. There are a few exceptions where the deeper navigation channel is closer to upland areas with wetlands inside well-maintained dike and levy systems, but again the wetlands are protected by the dikes and isolated to some extent from the river. However, limited impacts on wetland habitats attributed to shoreline erosion may occur as a result of the proposed project. As described in section 4.1.2.3, FERC staff continues to study this issue and additional analysis regarding shoreline erosion will be included in the revised BA and EFH Assessment. If applicable, mitigation for impacts on wetlands along the waterway would be included in NorthernStar's final Compensatory Mitigation Plan. Because NorthernStar's Compensatory Mitigation Plan has not been finalized, we recommended in section 2.1.5 that NorthernStar continue to consult with the COE, NMFS, FWS, ODFW, ODSL, WDE, and other appropriate agencies to finalize its Compensatory Mitigation Plan.

During transit to the LNG terminal, the potential exists for an accidental or intentional breach of an LNG carrier resulting in a release of LNG. However, LNG is less dense than freshwater or saltwater so it would float on the surface. Immediately upon contact with any warmer substance such as water or air, it would begin to evaporate. Because LNG is not soluble in water and the LNG would completely vaporize shortly after being spilled, there would be no liquid left that could mix with and/or contaminate the water or sediments. As the LNG vaporizes, a vapor cloud may form that is initially heavier than air and may be dispersed by wind. An LNG vapor cloud cannot explode in the open atmosphere, but can burn. If the LNG vapor cloud were to burn, wetland vegetation along the Columbia River could be damaged. However, the area of effect of an LNG release and any resulting fire would be fairly limited and short-lived, unless conditions were such that a forest fire was triggered (see section 4.4.2.1). Affected areas would likely revegetate naturally except in the immediate vicinity of the breach. With implementation of the mitigation measures described in the Coast Guard's WSR (Appendix G), a release would be highly unlikely, and therefore, the potential impacts on wetlands would be less than significant.

4.4.1.2 LNG Terminal

Wetlands within the proposed LNG terminal area were delineated in accordance with the 1987 COE Wetland Delineation Manual (Environmental Laboratory, 1987) and Oregon State Wetland Delineation Report Guidance (ODSL, 2000). Wetland delineations were conducted at the proposed terminal site by the Columbia River Estuary Study Taskforce (CREST) in July, 2003. Wetland

boundaries delineated by the CREST were subsequently approved by the ODSL in July 2005. Additional field surveys were conducted by Rhea Environmental Consulting, LLC (Rhea) and URS in 2005 to include expanded areas outside the original survey area. In September 2006, all wetlands previously delineated by the CREST within the study area were verified and, in many cases, expanded by URS. The 2006 URS delineation reclassified the estuarine wetlands at the LNG terminal site as palustrine. An explanation was not provided for the change.

Common wetland vegetation identified during the field surveys of the proposed LNG terminal site is presented in table 4.4.1-1.

TABLE 4.4.1-1			
Common Wetland Species Identified in Delineations Within the Bradwood Landing LNG Terminal Site			
Common Name	Scientific Name	Common Name	Scientific Name
Red alder	<i>Alnus rubra</i>	Reed canary-grass	<i>Phalaris arundinacea</i>
Slough sedge	<i>Carex obnupta</i>	Creeping buttercup	<i>Ranunculus repens</i>
Giant horsetail	<i>Equisetum arvense</i>	Himalayan blackberry	<i>Rubus discolor</i>
Common velvetgrass	<i>Holcus lanatus</i>	Sitka willow	<i>Salix sitchensis</i>
Paleyellow iris	<i>Iris Pseudacorus</i>	Small-fruited bulrush	<i>Scirpus microcarpus</i>
Common rush	<i>Juncus effuses</i>	Rose spiraea	<i>Spiraea douglasii</i>
Purple loosestrife	<i>Lythrum salicaria</i>	Skunk cabbage	<i>Symplocarpus foetidus</i>
Water parsely	<i>Oenanthe sarmentosa</i>	Cattail	<i>Typha latifolia</i>

Impacts and Mitigation

A total of 13 wetlands were identified within the proposed LNG terminal site, including forested, scrub-shrub, and emergent wetlands as well as unconsolidated shores and bottoms. In addition, 3,000 feet of unconsolidated shore along the Columbia River would also be affected by the proposed project. Construction of the LNG terminal facilities would result in temporary impacts on 14.8 acres of wetlands. Permanent wetland impacts at the LNG terminal would include: 2.7 acres of scrub-shrub wetlands, 5.7 acres of emergent wetlands, and 4.5 acres of area that includes multiple wetland types. The majority of these wetlands have been previously disturbed by industrial activities, including the installation of a railroad, site grading, excavation, and road construction.

Since the issuance of the draft EIS, NorthernStar has proposed modifications to Bradwood and Clifton Roads and has stated that a parking lot would be provided for construction workers southeast of the Taylorville interchange at Highway 30. NorthernStar has not submitted information to the FERC regarding vegetation or other resource impacts at these locations. Therefore we recommended in section 4.2.2.1 that NorthernStar quantify and file impacts on wetlands associated with the modifications to Bradwood and Clifton Roads as well as the new proposed construction worker parking lot prior to construction.

Table 4.4.1-2 summarizes the potential impacts on wetlands associated with the construction and operation of the proposed LNG terminal. Figure 4.4.1-2 depicts the wetlands delineated within the proposed LNG terminal site.

^a Cowardin Classification System: PEM = Palustrine emergent PSS = Palustrine scrub-shrub PFO = Palustrine forested wetland ^b Construction impacts include temporary disturbances related to construction of the LNG terminal and associated facilities. ^c Operational impacts include the permanent loss of wetlands within the footprint of the facility. ^d Sum of addends may not equal total due to rounding.			

Nonjurisdictional facilities associated with the proposed LNG terminal include a 1.5-mile-long power line and three lateral pipelines. As discussed in section 2.2.2, the lateral pipelines would be constructed by entities other than NorthernStar and are tentative at this time. The power line would require a 100-foot-wide right-of-way for construction and operation. A 400-foot-wide corridor centered over the proposed route was examined to allow for some flexibility in the final routing of the power line. Approximately 2.2 acres of wetlands were identified within the 400-foot-wide corridor, including 1.7 acres of forested wetlands, 0.3 acre of scrub-shrub wetlands, and 0.2 acre of emergent wetlands. Table 4.4.1-3 lists the wetlands identified within the 400-foot-wide corridor.

The impacts of project-related construction and operation activities on wetlands would vary depending on the timing of construction, construction techniques used, the sensitivity of the resources disturbed, and the length of time required for wetlands to be restored. Soil disturbance and removal of wetland vegetation within the project area could temporarily affect the capacity of wetlands to buffer flood flows and could increase the potential for erosion. Removal of wetland vegetation could also deprive wildlife of a valuable habitat component and encourage the recruitment of less desirable invasive species. Rutting of soils from construction equipment could result in soil mixing and a disruption of surface water flow, which could also affect the success of post-construction restoration. Uncontrolled surface runoff from adjacent disturbed upland areas could transfer sediment into off-site wetlands. Accidental spills and leaks from construction equipment could also result in wetland contamination and some loss of wetland values/functions as wildlife habitat could be diminished during construction.

The majority of impacts related to the operation of the LNG terminal would be permanent and result in the conversion of wetlands to commercial/industrial uses. NorthernStar would mitigate construction-related impacts by implementing its terminal ESC Plan and our Procedures, and by complying with the COE's section 404 and ODSL's section 401 permit conditions.

In order for the COE to determine whether practicable alternatives have been taken, NorthernStar is required to avoid impacts on wetlands to the maximum extent possible. NorthernStar must also demonstrate that it has taken appropriate and practicable steps to minimize wetland impacts in compliance with the COE's section 404(b)(1) guidelines that restrict discharges of dredged or fill material where a less environmentally damaging alternative exists. When unavoidable wetland impacts are proposed, the COE and ODSL would require that all practicable actions be taken to mitigate those impacts. This is consistent with the CEQ's Regulations for Implementing the Procedural Provisions of the NEPA (40 CFR 1508.20), which defines mitigation to include the following criteria:

- avoiding the impact altogether by not taking a certain action or parts of an action;
- minimizing impacts by limiting the degree or magnitude of the action and its implementation;

- rectifying the impact by repairing, rehabilitating, or restoring the affected environment;
- reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action; and
- compensating for the impact by replacing or providing substitute resources or environments.

For any large construction project, there is the potential for spills or leaks of fuels or hazardous materials from storage containers, equipment working in or near wetlands, and fuel transfers to adversely affect wetlands. NorthernStar would minimize the potential for spills by implementing its terminal ESC Plan. Specifically, NorthernStar would limit the refueling of equipment within 100 feet of wetlands, inspect all equipment and vehicles for leaks before entering wetlands, and wash all equipment and vehicles to remove any residual petroleum material before construction within wetlands.

Along the Columbia River shoreline, NorthernStar would implement its *Terminal Site Conceptual Revegetation Plan* that identifies specific revegetation practices within four vegetative zones (i.e., emergent zone, riparian low-shrub zone, riparian shrub zone, and upland herbaceous zone). Shoreline revegetation would include using potted plants, emergent plugs, and broadcast seed mixes to establish native herbaceous and woody species within these zones. The width of the zones would be variable, depending on the distance between the berm and the shoreline. The emergent zone would be located just below the MHHW line where daily tidal inundation occurs and would be planted with low-growing emergent vegetation with mature heights not exceeding 3 feet. The riparian low-shrub zone is located where the berm is nearest the shoreline, near the southern edge of the property. The area between the MHHW line and the toe of the berm would be planted with typical low-growing riparian shrub species, including Columbia River willow and red-osier dogwood, with mature heights of about 10 feet and 16 feet, respectively. The riparian shrub zone would be installed from the MHHW line upslope to approximately 2 feet above the MHHW line. Species planted would consist of typical forested riparian trees and shrubs with mature heights 16 feet and greater. The upland herbaceous zone would be located between the riparian zone and the toe of the berm and would vary in width depending on the distance from the berm to the shoreline. This zone would consist of low-growing native herbaceous species, including lupine species and native grass species with mature heights less than 5 feet. Additional information on the *Terminal Site Conceptual Revegetation Plan* as it relates to upland vegetative communities is included in section 4.4.2.2.

Compensatory Mitigation

NorthernStar has made a commitment that the proposed project would provide an overall significant net benefit to the environment of the lower Columbia River ecosystem. As described in its Compensatory Mitigation Plan, NorthernStar would approach wetland mitigation first through impact avoidance, then minimization, and finally through compensation (i.e., protection, restoration, creation, and enhancement).

Following temporary wetland impacts resulting from construction of the proposed project facilities, habitat and ecosystem function would be restored in place. Permanent impacts on wetlands would be mitigated by restoring habitat with similar ecological function. Mitigation would occur in areas substantially larger than that lost to permanent impacts, and would be restored to a higher level of ecosystem function.

Construction of the proposed LNG terminal would result in permanent and temporary wetland impacts. Temporary impacts within the proposed LNG terminal site would include shoreline impacts

resulting from the construction of the 5-foot containment berm that would surround the perimeter of the facility. Shoreline restoration would occur following construction of the berm and would be maintained until the revegetation areas meet performance standards. Vegetation would be planted during its dormant period to avoid mortality due to heat stress or drought.

Following construction of the LNG terminal, permanent impacts on wetlands would be mitigated through the implementation of NorthernStar's Compensatory Mitigation Plan. The Svensen Island Mitigation Sites would be the primary wetland mitigation sites in Oregon and are located about 14 miles downstream of the proposed Bradwood Landing LNG terminal in Clatsop County, Oregon (see figure 2.1.5-1). In addition, the Hunt Creek Mitigation Site would include preservation of wetland habitats adjacent to the LNG terminal site. This mitigation site is summarized below and discussed in detail in section 4.5.2.1.

The Svensen Island Mitigation Sites must succeed on several levels in order to offset resource impacts resulting from construction of the proposed LNG terminal. Generally, success would be determined by the applicant's ability to establish estuarine wetland conditions that would result in the capacity and opportunity to provide wetland functions at or greater than the capacity that would be lost at the impact site. The successful mitigation sites would restore, create, and/or enhance aquatic and terrestrial habitat; promote native species richness; and preserve existing high quality wetland areas. Factors that could limit the success of the mitigation sites include inaccurate water budget modeling, inaccurate grading elevations, barriers to fish passage, inaccurate plant species selections for the relevant hydrologic regimes, poor water quality, failure to obtain conservation easements or deed restrictions, failed plantings, and/or competition with non-native invasive plant species. A biologist would be present during construction of the mitigation sites to ensure that the sites are built without impacting adjacent fish habitat, to monitor grading activities, and to advise on construction procedures in order to ensure that the sites are constructed to plan. All seed mixes would be certified weed free.

In order to provide mitigation that is recognized as robust relative to the typical regulatory requirements, NorthernStar is proposing preservation and maintenance of an additional wetland area, the Hunt Creek Mitigation Site (see section 4.5.2.1 for a description of this site). This area would qualify as "Conservation in lieu" sites under Oregon DSL's CWM requirements because the site supports substantial populations of federally listed salmonids. Under the CWM program, there is no established ratio of conservation area relative to impact area.

The FERC received numerous comments stating that the mitigation proposed by NorthernStar does not adequately compensate for wetland impacts associated with the project. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. Because NorthernStar's Compensatory Mitigation Plan has not been finalized, we recommended in section 2.1.5 that NorthernStar continue to consult with the COE, NMFS, FWS, ODFW, ODSL, WDE, and other appropriate agencies to finalize its Compensatory Mitigation Plan.

4.4.1.3 Pipeline Facilities

Wetlands within the pipeline project area were delineated in accordance with the 1987 COE Wetland Delineation Manual (Environmental Laboratory, 1987), Oregon State Wetland Delineation Report Guidance (ODSL, 2000), and the Washington State Wetlands Identification and Delineation Manual (WDE, 1997). Between March and June 2006, URS conducted field surveys, where access was allowed, along a 200-foot-wide survey corridor centered over the proposed pipeline to identify wetlands in the project area. In areas where access was not granted, field personnel relied on NWI maps, county soil surveys, and digital topographic maps with a stream overlay to identify wetlands.

Common wetland vegetation identified during the field surveys of the proposed pipeline facilities is presented in table 4.4.1-4.

TABLE 4.4.1-4			
Common Wetland Species Identified in Delineations Within the Bradwood Landing Pipeline Area			
Common Name	Scientific Name	Common Name	Scientific Name
Emergent Wetlands			
Colonial bentgrass	<i>Agrostis capillaries</i>	Perennial ryegrass	<i>Lolium perenne</i>
Ladyfern	<i>Athyrium filix-femina</i>	Bird's-foot trefoil	<i>Lotus corniculatus</i>
Slough sedge	<i>Carex obnupta</i>	Water primrose	<i>Ludwigia palustris</i>
Coontail	<i>Ceratophyllum demersum</i>	Field mint	<i>Mentha arvensis</i>
Ovate spike-rush	<i>Eleocharis ovata</i>	Reed canary-grass	<i>Phalaris arundinacea</i>
Giant horsetail	<i>Equisetum arvense</i>	Kentucky bluegrass	<i>Poa pratensis</i>
Tall fescue	<i>Festuca arundinacea</i>	Water smartweed	<i>Polygonum amphibium</i>
Common velvetgrass	<i>Holcus lanatus</i>	Waterpepper	<i>Polygonum hydropiperoides</i>
Marsh pennywort	<i>Hydrocotyl ranunculoides</i>	Pondweed	<i>Potamogeton natens</i>
Jewel weed	<i>Impatiens noli-tangere</i>	Clasping-leaved pondweed	<i>Potamogeton richardsonii</i>
Common rush	<i>Juncus effuses</i>	Creeping buttercup	<i>Ranunculus repens</i>
Common duckweed	<i>Lemna minor</i>	White clover	<i>Trifolium repens</i>
Scrub-Shrub Wetlands			
Common rush	<i>Juncus effuses</i>	Black cottonwood	<i>Populus balsamifera</i>
Dagger-leaf rush	<i>Juncus ensifolius</i>	Cattail	<i>Typha</i> spp.
Bird's-foot trefoil	<i>Lotus corniculatus</i>	Red huckleberry	<i>Vaccinium parvifolium</i>
Forested Wetlands			
Vine maple	<i>Acer circinatum</i>	Jewel weed	<i>Impatiens noli-tangere</i>
Bigleaf maple	<i>Acer macrophyllum</i>	Common rush	<i>Juncus effuses</i>
Colonial bentgrass	<i>Agrostis capillaries</i>	Water parsely	<i>Oenanthe sarmentosa</i>
Red alder	<i>Alnus rubra</i>	Reed canary-grass	<i>Phalaris arundinacea</i>
Ladyfern	<i>Athyrium filix-femina</i>	Black cottonwood	<i>Populus balsamifera</i>
Slough sedge	<i>Carex obnupta</i>	Himalayan blackberry	<i>Rubus discolor</i>
Red-osier dogwood	<i>Cornus stolonifera</i>	Salmonberry	<i>Rubus spectabilis</i>
Scouring-rush	<i>Equisetum hyemale</i>	Sitka willow	<i>Salix sitchensis</i>
Tall fescue	<i>Festuca arundinacea</i>	Rose spiraea	<i>Spiraea douglasii</i>
Oregon ash	<i>Fraxinus latifolia</i>	Skunk cabbage	<i>Symplocarpus foetidus</i>
Common velvetgrass	<i>Holcus lanatus</i>	Youth-on-age	<i>Tolmiea menziesii</i>

Impacts and Mitigation

A detailed list of wetlands affected by the proposed pipeline facilities is provided in table 4.4.1-5. Table 4.4.1-6 summarizes the impacts associated with the construction and operation of the proposed pipeline facilities on wetlands. Construction of the pipeline facilities would temporarily affect approximately 97.9 acres of wetlands including about 5.0 acres of forested wetlands, 0.4 acre of scrub-shrub wetlands, 49.2 acres of emergent wetlands, and 43.3 acres of area that include multiple wetland types. Operation of the pipeline facilities would permanently affect approximately 14.7 acres of wetlands. Emergent and scrub-shrub wetlands would be allowed to revert to preconstruction conditions following construction. Therefore, operational impacts would consist of the permanent conversion of forested wetlands to other wetland types.

Cowlitz, Washington	1.7	0.5	0.4	--	3.5	--	0.3	0.1
Total	5.0	1.8	0.4	--	49.2	--	43.3	12.9
^a	Construction impacts for the pipeline are based on an 85- to 100-foot-wide right-of-way and additional temporary workspaces.							
^b	Operational impacts are based on the crossing length of the pipeline in all wetlands containing forested wetland areas and a 30-foot-wide maintained right-of-way. This includes a 10-foot-wide strip (centered over the pipeline) that would be permanently maintained as herbaceous wetland during operation of the project. In addition, trees within 15 feet of the pipeline greater than 15 feet in height may be selectively cut and removed from the permanent right-of-way.							
^c	Operational impacts on scrub-shrub and emergent wetlands would be avoided because herbaceous and scrub-shrub wetland vegetation in the pipeline right-of-way is generally not mowed or otherwise maintained.							

Although our Procedures require that additional temporary workspaces be located at least 50 feet from waterbodies and wetland boundaries, NorthernStar identified 22 locations where additional temporary workspace is proposed to be located entirely or partially within wetlands or within 50 feet of a wetland. The wetland impacts resulting from these workspaces are included in the acreages presented in table 4.4.1-5.

None of the aboveground facilities associated with the proposed pipeline would be located in wetlands. Similarly, the pipe storage and contractor yard in Oregon would not be located in wetlands. However, the pipe and contractor yard in Washington at Longview has a drainage ditch adjacent to the southwestern side of the yard and another ditch runs through the southwestern corner of the property. The yard is an existing industrial site. However, NorthernStar has not filed either wetland delineations for the site or a statement that impacts on the wetlands depicted on figure 2.3.3-2 would be avoided. Therefore, **we recommend that:**

- **Prior to activities within the pipe storage and contractor yard in Washington, wetlands potentially affected by activities within the yard should be fenced. Construction activities should not occur within 50 feet of any wetland without prior review and written approval by the Director of OEP.**

NorthernStar would use existing access roads which would not require modification or improvement and would, therefore, not represent any additional impacts on wetlands.

NorthernStar would cross 21 wetlands along the proposed pipeline route using the HDD method. Clearing within areas crossed using the HDD method would be limited to hand trimming associated with the temporary deployment of HDD guidance (telemetry) cables (see section 4.3.2.4). If a frac-out were to occur, NorthernStar would implement its *HDD Contingency Plan*, which describes procedures and measures to be taken in the event of a frac-out. NorthernStar would station the necessary equipment and supplies to respond to a frac-out upon discovery of loss of drilling fluid at each HDD site. At the time of a frac-out, NorthernStar would stop drilling immediately, contain drilling fluids, and notify appropriate agencies. Appropriate resource experts (e.g., fisheries biologists and wetland scientists) would be on site

to monitor resources and effects of the release. To avoid wetland impacts at these locations during pipeline operation, NorthernStar would not maintain the right-of-way between the HDD entrance and exit locations. However, some of the additional temporary workspaces needed for HDD entry and exit points and pipe stringing could result in temporary impacts on wetlands.

The push-pull construction method is generally used in large wetland areas with suitable hydrology and topography (i.e., flooded or saturated soils and minimal local relief). In push-pull construction, the equipment required to place the pipeline in the trench is generally positioned at either end of the wetland crossing, and the pipeline is “floated” into position using a system of floats and rollers. Push-pull construction generally requires a narrower right-of-way and minimizes the operation of construction equipment within wetlands. As such, this method offers environmental advantages over conventional wetland construction approaches. Because of the potential environmental advantages of the push-pull construction method, this method should be used where sufficient water is present in the trench and other site conditions allow. NorthernStar would utilize the push-pull method where appropriate site-specific conditions are present at the time of construction. However, wetland conditions may preclude the use of the push-pull method.

As discussed in section 4.4.1.2, the impacts of project-related construction and operation activities on wetlands would vary depending on the timing of construction, construction techniques used, the sensitivity of the resources disturbed, and the length of time required for wetlands to be restored. The primary impact of pipeline construction and right-of-way maintenance activities on wetlands would be the temporary and permanent alteration of wetland vegetation. These effects would be greatest during and immediately following construction. In general, wetland impacts would be minimized by avoidance, mitigation of impacts, and compensation in accordance with federal, state, and local regulations. Typical pipeline construction methods when in wetlands are described in section 2.4.2.2. NorthernStar would mitigate construction-related impacts by implementing its *Waterbody and Wetland Construction and Mitigation Procedures Plan*, pipeline ESC Plan and SWPPP, and our Procedures. In addition, NorthernStar would comply with the COE's section 404 and ODSL's and WDE's section 401 permit conditions. As discussed in section 4.4.1.2, NorthernStar is required to avoid impacts on wetlands to the maximum extent possible and must demonstrate that it has taken appropriate and practicable steps to minimize wetland impacts in compliance with the COE's section 404(b)(1) guidelines that restrict discharges of dredged or fill material where a less environmentally damaging alternative exists. This is consistent with the CEQ's Regulations for Implementing the Procedural Provisions of the NEPA (40 CFR 1508.20), as further described in section 4.4.1.2. All necessary federal, state, and local permits described in table 1.3-1 would be obtained prior to the commencement of construction activities.

For any large construction project, there is the potential for spills or leaks of fuels or other hazardous materials from storage containers, equipment working in or near wetlands, and fuel transfers. The introduction of fuels or other hazardous materials as a result of spills or leaking equipment could also adversely affect these wetlands. NorthernStar would minimize the potential for spills by implementing its pipeline ESC Plan, SWPPP, and *Waterbody and Wetland Construction and Mitigation Procedures Plan* as well as our Procedures. Specifically, NorthernStar would limit the refueling of equipment within 100 feet of wetlands, inspect all equipment and vehicles for leaks before entering wetlands, and wash all equipment and vehicles to remove any residual petroleum material before construction within wetlands.

Wetlands temporarily affected by installation of the pipeline would be restored immediately following construction by grading sites back to their original contours with the topsoil replaced above the subsoil. Surface and sub-surface hydrology characteristics, including impermeable soil layers, within the trench would be identified and restored using native on-site material, imported clay, or bentonite during backfilling. To facilitate the restoration of perennial native vegetation in unsaturated wetlands, most vegetation would be replaced by seeding with conservation grasses, legumes, native herbaceous species,

or other standard erosion control/cover species, where required. Saturated wetlands would typically be re-vegetated by salvaging and maintaining appropriate specimens prior to construction for transplanting back into the wetland after construction is complete. The specimens would be maintained at the edge of the construction corridor or in a nearby staging area and kept viable by shading, watering, and mulching during pipeline construction. Upon restoring grade over the new pipeline, the salvaged wetland vegetation would be replanted in appropriate locations. If rare or unusual species are observed within the construction corridor, these would be salvaged and transplanted to restore the natural biodiversity of the impacted wetlands.

Generally, wetland communities would eventually transition back into a community with functionality similar to that of the wetland before construction. The herbaceous vegetation in emergent wetlands would regenerate quickly (typically within 1 to 3 years). Following revegetation, there would be little permanent impact on emergent wetland vegetation in the maintained right-of-way because these areas naturally consist of and would remain as an open and herbaceous community. Herbaceous wetland vegetation in the pipeline right-of-way is not generally mowed or otherwise maintained, although the FERC staff's Procedures allow annual maintenance of a 10-foot-wide strip centered over the pipeline.

Scrub-shrub wetlands could take several years to reach functionality similar to preconstruction conditions, depending on the age and complexity of the system. Forested wetlands would be replanted with in-kind wetland tree specimens (post-construction species composition would be similar to pre-construction composition), with the exception of the portion of the right-of-way within 5 feet of the pipeline (10 feet total), thereby minimizing the extent of disturbance. However, trees planted between 5 and 15 feet from the pipeline would be limited to a maximum height of 15 feet to allow for aerial inspection of the pipeline. NorthernStar's proposed tree planting exceeds the revegetation requirements of the FERC staff's Procedures. The corridor centered on the pipeline would be planted with a native grass seed mix and maintained in an herbaceous state to facilitate maintenance and inspection. Nearly complete canopy coverage over the pipeline would be expected to develop in most areas within approximately 20 years.

FERC Staff's Procedures

To avoid or minimize impacts on wetlands, NorthernStar would implement measures outlined in our Procedures during the construction and operation of the proposed LNG terminal and pipeline facilities. Our Procedures include, but are not limited to, the following requirements:

- Construction equipment operating within the right-of-way would be limited to that equipment necessary for clearing, excavation, pipe installation, backfilling, and restoration activities. All nonessential equipment would use upland access roads to the maximum extent practicable.
- Equipment operating within saturated wetlands would be low-ground-weight equipment or would operate from prefabricated construction mats.
- Temporary erosion and sedimentation control measures would be installed immediately after the initial disturbance of wetland soils and would be inspected and maintained regularly until final stabilization.
- Sedimentation controls would be installed across the construction right-of-way within wetlands to contain trench spoil, as needed.
- Grading and pulling of tree stumps would be limited to the area directly over the trenchline unless additional grading or stump removal is required for worker safety.

- In unsaturated wetlands, the uppermost 12 inches of topsoil along the pipeline trench would be segregated from the underlying subsoil.
- The appropriate land management or state agency should be consulted to develop a project-specific wetland restoration plan. The restoration plan should include measures for re-establishing herbaceous and/or woody species, controlling the invasion and spread of undesirable exotic species, and monitoring the success of revegetation and weed control efforts.

NorthernStar has stated that monitoring of wetlands would be conducted for a minimum of 3 years post-construction to ensure the success of wetland revegetation, if revegetation is not successful after 3 years, a remedial revegetation plan would be developed and implemented. However, comments were received on the draft EIS stating that the proposed duration of wetland monitoring is not adequate to ensure the success of revegetation along the right-of-way. Therefore, to ensure compliance with our Procedures, we have recommended in section 4.3.2.4 that NorthernStar continue to consult with the COE, NMFS, FWS, and appropriate federal and state agencies to finalize its *Waterbody and Wetland Construction and Mitigation Procedures Plan*, including procedures for monitoring the success of the revegetation.

Requested Modifications to the FERC's Staff's Procedures

NorthernStar's ESC Plans, SWPPP, and *Waterbody and Wetland Construction and Mitigation Procedures Plan* integrate the FERC staff's Procedures, with certain exceptions. The intent of the FERC staff's Procedures is to assist applicants by identifying baseline mitigation measures for minimizing the extent and duration of disturbances to soils, wetlands, and waterbodies associated with projects under the FERC's jurisdiction throughout the country. Included below is a description of NorthernStar's proposal to modify certain baseline mitigation measures included in our Procedures.

Construction Right-of-way Width in Wetlands

Item VI.A.3 of our Procedures requires that the construction right-of-way width in wetlands be limited to 75 feet. NorthernStar proposes to use an 85-foot-wide construction right-of-way within all wetlands where the crossing length is less than 100 feet and a 100-foot construction right-of-way where the crossing length is greater than 100 feet. NorthernStar's justification for the wider right-of-way is based on the following site-specific conditions:

- A minimum of 4 inches of concrete coating would be required to maintain negative buoyancy of the 36-inch-diameter pipe in wetlands. When combined with the natural weight of the steel pipe, this poses a challenge even for large side booms (Caterpillar 589s), which would require matting in wetland areas to achieve adequate load bearing capacity.
- Ditch depth would be a minimum of 7 to 7.5 feet to accommodate the pipeline dimensions, including the concrete coating, and minimum soil cover requirements.
- The soils in the project area would naturally slump to a 1:2 or flatter slope, resulting in excessive ditch widths. Once excavated, the soils would have a fluid consistency, resulting in the need for additional workspace to contain the spoil piles.
- Except in saturated wetlands, topsoil would be segregated and stored separately, as required by the Procedures. At least 2 feet of separation between the segregated topsoil and the trench spoil would be required to prevent intermingling.

- The volume of the excavated spoil material is expected to swell 30 percent upon excavation.
- To prevent sloughing of the excavated material back into the trench, excavated materials would be placed at least 4 feet from the edge of the trench, pipe would be strung no closer than 4 feet from the trench, and equipment operation would not occur within 6 feet of the excavated trench for safety.
- Excavated materials would be placed a minimum of 2 feet inside the sediment barriers, which in turn would be placed a minimum of 1 foot inside the construction right-of-way, in an effort to prevent any off right-of-way disturbance.

Based on the information provided by NorthernStar, the proposed 85-foot and 100-foot-wide right-of-way is necessary and justified to allow for safe and efficient construction of the pipeline in wetlands.

Additional Temporary Workspaces within 50 Feet of Wetland Boundaries

Item VI.B.1.a of our Procedures requires that all additional temporary workspaces such as staging areas and additional spoil storage areas be located at least 50 feet from wetland boundaries except where the adjacent upland consists of cropland. However, we have identified 5 additional temporary workspaces that would be within 50 feet of wetland boundaries and 17 additional temporary workspaces that are proposed to be located entirely or partially within wetlands.

Consistent with our Procedures, additional temporary workspaces should be located at least 50 feet outside of wetland boundaries where topographic conditions permit. However, we recognize that certain site-specific conditions may require placing additional temporary workspaces within wetlands or within 50 feet of a wetland boundary. We have reviewed the locations where additional temporary workspaces have been sited in or within 50 feet of a wetland, and our conclusions are provided in table 4.4.1-7. During the comment period on the draft EIS, NorthernStar provided additional information on the temporary workspaces within 50 feet of wetlands that the FERC staff previously did not find acceptable. In review of that new information, the FERC staff found that for all but three remaining locations, NorthernStar had justified why it should be allowed to place the temporary extra workspace within 50 feet of a wetland. However, based on the revised locations provided by NorthernStar in its December 21, 2007 submittal, in three cases the FERC staff was not satisfied, and therefore we recommend that:

- **During construction, NorthernStar should implement the following measures at the three temporary extra workspaces listed below and in table 4.4.1-7 that would be within 50 feet of wetlands.**
 - a. **B0505 – Wetland should be fenced and avoided regardless of the presence of saturated conditions during construction activities.**
 - b. **EST-3 – The pull string section for the Abernathy Creek HDD should avoid this wetland and the waterbody located within the wetland boundaries.**
 - c. **AA0424 – The extra workspace should be relocated and centered on the upland area approximately 250 feet west of the current location.**

TABLE 4.4.1-7

NorthernStar's Request to Locate Additional Temporary Workspaces Within 50 feet of a Wetland			
MP	Wetland ID	Rationale for Additional Temporary Workspace	Conclusion and Approval Status
Additional Temporary Workspace within 50 feet of Wetlands			
3.8	B0511	HDD pipe pull string laydown	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
4.8	B0505	HDD entry pit – Westport Slough	FERC staff recommends additional revisions.
4.9	C0505	HDD entry pit – Westport Slough	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
19.0	DD0523	HDD exit pit – Columbia River	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
36.2	AA0426	Meter Station – End of route	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
Additional Temporary Workspace Located within Wetlands			
5.4	B0608	HDD exit pit – Westport Slough	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
5.5	A0608	HDD pipe pull string laydown – Westport Slough	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
8.4	AA0508	HDD entry pit – Kelli Slough and Woodson Road	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
8.7	EST-1	HDD exit pit and pipe pull string laydown – Kelli Slough and Woodson Road	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
8.9	BB0512	HDD pipe pull string laydown – Kelli Slough and Woodson Road	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
9.9	AA0511	HDD entry pit – Midland Canal	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
10.2	EST-3	HDD exit pit and pipe pull string laydown – Midland Canal	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
13.1	EST-6	HDD entry pit – Clatskanie River	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
18.1	AA0523	HDD pipe string laydown – Columbia River	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
18.1	BB0523	HDD pipe string laydown – Columbia River	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
18.8	CC0523	HDD pipe string laydown – Columbia River	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
18.8	CC0523	Entry Pit – Road bore	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
21.4	EST-3	HDD pipe pull string laydown	FERC staff recommends additional revisions.
28.0	AA0424	Coal Creek Road and Coal Creek crossing	FERC staff recommends additional revisions.
34.2	A0504	HDD entry pit – Cowlitz River and Highway 411	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
34.8	A0517	HDD pipe pull string laydown and HDD exit pit – Interstate 5	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.
35.4	DD0426	HDD entry pit – Interstate 5	Given site-specific construction constraints, the location of this workspace is acceptable to the FERC staff.

Compensatory Mitigation

NorthernStar has made a commitment that the proposed project would provide an overall significant net benefit to the environment of the lower Columbia River ecosystem. As described in its Compensatory Mitigation Plan, NorthernStar would approach wetland mitigation first through impact avoidance, then minimization, and finally through compensation (i.e., protection, restoration, creation, and enhancement).

Following construction of the proposed pipeline, habitat and ecosystem function would be restored in place. Permanent impacts on wetlands would be mitigated by preserving or restoring habitat in the general project area with similar ecological function. Mitigation would occur in areas substantially larger than those lost to permanent impacts, and would be restored to a higher level of ecosystem function. Due to the separate regulatory jurisdictions, wetland impacts would be mitigated separately in Oregon and Washington.

As described in section 4.4.1.2, within Oregon, the Svensen Island Mitigation Sites would be the primary wetland mitigation sites, although the Hunt Creek Mitigation Site would be preserved and also contains wetland habitats. NorthernStar has identified the Delameter Creek Mitigation Site as the primary mitigation site for wetland impacts in Washington.

The FERC received numerous comments stating that the mitigation proposed by NorthernStar does not adequately compensate for wetland impacts associated with the project. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. Because NorthernStar's Compensatory Mitigation Plan has not been finalized, we have recommended that NorthernStar continue to consult with the COE, NMFS, FWS, ODFW, ODSL, WDE, and other appropriate agencies to finalize its Compensatory Mitigation Plan.

4.4.2 Upland Vegetation

The Bradwood Landing Project would be located in the northwestern portion of Oregon and the southwestern portion of Washington. This area falls within portions of three ecoregions, including the Coast Range, Puget Lowland Forest, and Cascades ecoregions (Thorson et al., 2003). The climate in these regions is marine influenced and abundant precipitation occurs during the fall, winter, and spring months. Historically, Sitka spruce (*Picea sitchensis*) and coastal redwood (*Sequoia sempervirens*) forests dominated coastal areas, while a mosaic of western red cedar (*Thuja plicata*), western hemlock (*Tsuga heterophylla*), and seral Douglas-fir (*Pseudotsuga menziesii*) were found in inland areas. Today, Douglas-fir plantations are prevalent on the intensively logged and managed landscape (Thorson et al., 2003). Within these ecoregions, 10 distinct upland vegetative communities have been identified that occur within the project area. These upland communities include the following: coniferous forest, deciduous forest, mixed forest, early seral forest, riparian forest, scrub-shrub, riparian scrub-shrub, agricultural and rangeland, dredged materials and bare ground, and developed areas.

Coniferous forest is comprised primarily of mid-successional (typical) conifer-dominated forest with trees aged between 20 and 80 years that have been planted for commercial timber, and to a lesser extent, late-successional (high-quality) remnant native coniferous forest with mature trees aged greater than 80 years. These forests are comprised of dense, even-aged stands of Douglas-fir, with a few occurrences of other species, including red alder (*Alnus rubra*) and western hemlock. Commercial timberland is present throughout both Oregon and Washington along the lower Columbia River, including the Zones of Concern.

Deciduous forest is comprised of mature cottonwoods (*Populus* spp.), willows (*Salix* spp.), red-osier dogwood, young red alder, and bigleaf maple (*Acer macrophyllum*). Understory species include salmonberry (*Rubus spectabilis*), swordfern (*Polystichum munitum*), vine maple (*Acer circinatum*), beaked hazelnut (*Corylus cornuta*), youth-on-age (*Tomiea menziesii*), and the invasive Himalayan blackberry.

Mixed forests are comprised of both deciduous and coniferous trees, but the dominant species are usually deciduous. Typical species include big-leaf maple, red alder, Douglas-fir, and western red cedar

in the canopy layer with shrubs such as vine maple, beaked hazelnut, and salal (*Gaultheria shallon*) in the understory.

Early seral forest is characterized by clearcut areas that have begun to regenerate with a mixture of native Douglas-fir and red alder seedlings and saplings with a sometimes dense growth of nonnative, weedy species such as Himalayan blackberry. With age, this habitat develops into even-aged stands of Douglas-fir.

Dominant species found within riparian forest communities in the project area include cottonwood, red alder, and big-leaf maple. Typical understory species include vine maple, salmonberry, elderberry (*Sambucus* spp.), swordfern, ladyfern (*Athyrium filix-femina*), oxalis (*Oxalis* spp.), stinging nettle (*Urtica dioica*), and skunk cabbage (*Lysichiton americanum*).

Scrub-shrub communities are often the result of logging or fire and may be composed of native shrubs such as red huckleberry (*Vaccinium parvifolium*) and elderberry, with non-natives like Himalayan blackberry and Scotch broom (*Cytisus scoparius*) often being the dominant species.

Riparian scrub-shrub communities are comprised of cottonwood, Sitka spruce, red-osier dogwood, Sitka willow, and rose spiraea. Other common species include bulrush (*Scirpus* spp.), slough sedge (*Carex obnupta*), skunk cabbage, and cattail (*Typha* spp.).

Agricultural land, including pastures, orchards, and poplar plantations, are low-quality intensively managed areas that occur primarily as open pastures, fallow fields, and commercial poplar plantations. Because they lack vegetative diversity and structural complexity, they generally provide habitat for few species other than those that are edge-adapted.

Dredged spoils and bare ground are noted for their nearly complete lack of vegetation and exposed soils. Shallower areas of dredged sands may support limited vegetation, including nonnative Scotch broom and other weedy species.

Developed areas include buildings, roads, utility corridors, and other developed sites. These areas are usually devoid of vegetation and food resources and lack structural complexity.

4.4.2.1 Waterway for LNG Marine Traffic

Existing Upland Vegetation

The waterway for LNG marine traffic would be located within the Coast Range ecoregion. This ecoregion consists of highly productive, rain-drenched coniferous forests that cover the low mountains of the Coast Range. Timber lands in the area have generally been logged at least once, along with disturbance associated with agricultural and rural residential development. There are limited riparian conservation areas, and what vegetated riparian areas remain are dominated by hardwoods rather than more complex conifer forests, especially the once common “spruce swamp” or old-growth Sitka spruce-dominated wetlands.

Upland vegetative communities along the waterway and within the Zones of Concern include coniferous, deciduous, mixed, and early seral forests; upland and riparian scrub-shrub; agricultural; dredged spoils and bare ground; and developed areas. Typical species composition within these vegetative communities is described in section 4.4.2.

The WDFW has identified and mapped 18 Priority Habitats, which are defined as habitats that exhibit one or more of the following attributes: comparatively high fish and wildlife density or species diversity; important fish and wildlife breeding habitat, seasonal ranges, or movement corridors; limited availability; high vulnerability to habitat alteration; and/or unique or dependent species. Based on WDFW definitions, Priority Habitats include the Columbia River itself as well as estuarine areas between the mouth of the Columbia River and the LNG terminal. Maps detailing sensitive environmental features and habitats along the LNG carrier transit route are depicted in Appendix C.

General Impacts and Mitigation

The addition of 125 LNG carriers per year on the Columbia River would represent a 7 percent increase in commercial ship traffic and 25 percent increase in deep-draft vessel traffic. The wakes produced by an LNG carrier are only slightly larger than those of the large vessels currently using the Columbia River. However, as described in section 4.5.1.1, additional analysis of the potential for increased shoreline erosion due to LNG carrier wakes will be included in the revised BA and EFH Assessment. To minimize the potential for increased shoreline erosion due to LNG carrier transit, we recommended that NorthernStar coordinate with the NMFS to determine appropriate LNG carrier speed, or other applicable measures, to avoid or minimize shoreline erosion.

In the event of a collision or allision of sufficient magnitude to rupture an LNG cargo tank, it is likely that sparks or flames would ignite the flammable vapors at the spill site. In the unlikely event that ignition did not occur, an LNG spill would rapidly vaporize on water and form a potentially flammable cloud. If the flammable vapor cloud encountered an ignition source, the cloud would burn back to the spill site, rather than outward towards shoreline habitats. In the unlikely event of an LNG spill on water, ignition of the LNG vapors could contribute to a forest fire in areas where the Columbia River navigation channel is adjacent to forested areas (e.g., between Altoona and Skamokawa). Given the relatively high precipitation in the region, large forest fires in the area are infrequent, but they can be severe when they do occur. The intensity and extent of a potential forest fire would be highly dependent on a number of variables including available fuel (e.g., woody material), moisture and temperature, fuel composition, wind, and topography. However, as discussed in section 4.11.5, the risk of a release of LNG due to an accident or intentional breach during transit of the LNG carriers is very small and can be managed with safety and security measures described in the WSR (Appendix G). Therefore, the potential impacts on upland vegetative communities would be less than significant.

4.4.2.2 LNG Terminal

Existing Upland Vegetation

Table 4.4.2-1 lists the upland vegetative communities present within the proposed LNG terminal site as well as along of the proposed pipeline route. Based on categories described in the ODFW's HMP, essential deciduous forest, riparian forest, and riparian scrub-shrub habitats occur within the proposed LNG terminal site. Deciduous forests occur along the southern portion of the LNG terminal site as a narrow band between a large dredged material placement area and a patch of palustrine scrub-shrub wetland. Riparian forest occurs in two isolated patches along the Columbia River on the eastern edge of the site, and riparian scrub-shrub communities are limited to the areas adjacent to Hunt Creek.

TABLE 4.4.2-1						
Acres of Upland Vegetative Communities Affected by the Bradwood Landing Project						
Vegetative Community	LNG Terminal Facilities ^{a, b}		Pipeline Facilities ^{c, d}		Total	
	Construction	Operation	Construction	Operation	Construction	Operation
Coniferous forest	8.6	2.4	76.2	22.9	84.8	25.3
Deciduous forest	7.8	3.5	32.1	9.6	39.9	13.1
Mixed forest	0.0	0.0	52.2	15.7	52.2	15.7
Early seral forest	9.1	1.6	16.3	4.9	29.9	6.5
Riparian forest	0.7	0.5	2.9	0.9	3.6	1.4
Scrub-shrub	12.8	2.1	6.9	3.0	19.7	5.1
Riparian scrub-shrub	<0.1	<0.1	0.0	0.0	<0.1	<0.1
Agricultural and rangeland	0.0	0.0	98.6	41.6	98.6	41.6
Dredged materials and bare ground	21.3	19.3	0.6	0.4	21.9	19.7
Developed areas	4.6	3.5	42.7	8.5	47.8	12.0
Total	64.9	32.9	328.5	107.5	398.4	140.4
<p>Note: The totals shown in this table may not equal the sum of addends due to rounding.</p> <p>^a LNG terminal facilities include the Hunt Creek Bridge replacement, reroute of the railroad, and power line.</p> <p>^b Since the issuance of the draft EIS, modifications have been proposed to Clifton and Bradwood Roads and the construction worker parking area. Information quantifying these impacts on vegetative communities has not been provided.</p> <p>^c Acres impacted by construction based on the typical width of the temporary right-of-way being 100 feet and the typical permanent right-of-way width of 50 feet, except when crossing forested communities and most wetlands and streams as described in sections 4.4.2.3, 4.4.1.3, and 4.3.2.4, respectively.</p> <p>^d Estimated impacts on vegetative communities affected by construction and operation of the proposed pipeline do not include areas that would be crossed using the HDD method or existing access roads, as impacts on these areas would be avoided.</p>						

Impacts and Mitigation

Construction of the proposed LNG terminal facilities would affect about 64.9 acres of upland vegetation (see table 4.4.2-1). Specifically, this includes about 47.1 acres of upland vegetation for the LNG terminal and about 17.8 acres for the power line. The upland vegetative communities present on the LNG terminal site are categorized as deciduous and riparian forest, scrub-shrub, riparian scrub-shrub, dredged materials, and developed areas. Also present at the LNG terminal site are about 14.8 acres of wetlands and 63.5 acres of open water, which are discussed in sections 4.4.1.2 and 4.3.2.3, respectively.

LNG Terminal

As described above, 47.1 acres of upland vegetation would be impacted during construction of the LNG terminal. Following construction, 27.9 acres of uplands would be permanently converted to industrial use for operation of the LNG terminal. Currently, this area includes about 19.3 acres of dredged materials, 3.5 acres of developed areas, 2.5 acres of deciduous forest, 2.1 acres of scrub-shrub, 0.5 acre of riparian forest, and less than 0.1 acre of riparian scrub-shrub communities. As discussed above, the dredged material and developed areas include only limited vegetation; therefore, impacts would not be considered significant. Impacts on deciduous forest and scrub-shrub communities would not be significant on a regional scale because areas with similar vegetation characteristics are found on surrounding lands.

The greatest potential impacts on upland vegetation resulting from construction and operation of the LNG terminal would be on riparian forest communities due to their high productivity, species diversity, and contribution to both aquatic and upland ecosystem function (Knutson and Naef, 1997).

Based on concerns raised by the NMFS in its May 11, 2007 letter to the FERC, biologists from NorthernStar and URS surveyed the LNG terminal site in June 2007 to assess the number of cottonwood trees that would be removed within the riparian zone, which is the area within 300 feet of the Columbia River shoreline and adjacent Hunt Creek estuary up to the existing railroad alignment. Cottonwood trees over 20 feet in height were counted within seven discreet patches at the LNG terminal site. All trees less than 20 feet in height were not assessed because they are considered to be riparian scrub-shrub vegetation. Approximately 650 cottonwood trees were counted within the riparian zone. Of these, about 380 trees would be removed during construction of the LNG terminal. The remaining 270 trees would be preserved. Other tree species (i.e., Sitka spruce, red alder, Oregon ash, and bigleaf maple) occur within riparian forested areas at the LNG terminal site; however, they are not abundant (about 65 trees). The majority of the trees to be removed are located along the Hunt Creek estuary, along the northern edge of the proposed construction site boundary. Based on current design plans, NorthernStar proposes to preserve most trees along the Columbia River shoreline. However, trees that occur within 25 feet of the proposed fenceline would be removed for security reasons or topped below 25 feet and left with roots intact in order to provide habitat value (e.g., snags, perches).

The remaining 19.2 acres of uplands, which include 10.6 acres of scrub-shrub communities, 3.5 acres of early seral forest, 2.0 acres of dredged materials, 1.8 acres of deciduous forests, 1.1 acres of developed areas, and 0.2 acre of riparian forest areas would be restored after construction is completed. Restoration at the proposed LNG terminal site would be in accordance with NorthernStar's *Terminal Site Conceptual Revegetation Plan*.¹¹ In addition, NorthernStar would implement additional measures along the shorelines of the Columbia River and Hunt Creek as well as along the railroad right-of-way, as discussed below.

Along the Columbia River shoreline, NorthernStar would implement its *Terminal Site Conceptual Revegetation Plan* that identifies specific revegetation practices within four vegetative zones (i.e., emergent zone, riparian low-shrub zone, riparian shrub zone, and upland herbaceous zone). Shoreline revegetation would include using potted plants, emergent plugs, and broadcast seed mixes to establish native herbaceous and woody species within these zones. The width of the zones would be variable, depending on the distance between the berm and the shoreline. The emergent zone would be located just below the MHHW line where daily tidal inundation occurs and would be planted with low-growing emergent vegetation with mature heights not exceeding 3 feet. The riparian low-shrub zone is located where the berm is nearest the shoreline, near the southern edge of the property. The area between the MHHW line and the toe of the berm would be planted with typical low-growing riparian shrub species, including Columbia River willow and red-osier dogwood, with mature heights of about 10 feet and 16 feet, respectively. The riparian shrub zone would be installed from the MHHW line upslope to approximately 2 feet above the MHHW line. Species planted would consist of typical forested riparian trees and shrubs with mature heights 16 feet and greater. The upland herbaceous zone would be located between the riparian zone and the toe of the berm and would vary in width depending on the distance from the berm to the shoreline. This zone would consist of low-growing native herbaceous species, including lupine species and native grass species with mature heights less than 5 feet.

As described above, federal safety standards require that no trees taller than 25 feet be located within 25 feet of the security fence (located atop the perimeter berm). Therefore, along the northern portion of the shoreline, shrub and tree species with mature heights of less than 15 to 20 feet would be planted (or maintained where possible in areas that would not be cleared) within 25 feet of the security

¹¹ NorthernStar included its *Terminal Site Conceptual Revegetation Plan* as part of its JPA. NorthernStar filed its JPA with the FERC on November 22, 2006, and filed revisions to the JPA on April 5, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

fence. Along the southern portion of the shoreline, where the berm would be closest to the Columbia River, low-growing riparian shrub species would be installed within 25 feet of the security fence.

Adjacent to Hunt Creek, a riparian buffer at least 30 feet wide, as measured from the MHW mark, would be allowed to permanently revegetate in order to retain riparian function. NorthernStar would replace cleared trees at a 5:1 ratio within the LNG terminal site, resulting in about 1,895 trees being planted following construction. The majority of the replacement trees (e.g., cottonwood, Sitka spruce, red alder, Pacific willow, and other native species) would be installed within a 100-foot buffer along the northern edge of the proposed construction boundary. This area would serve as a forested buffer from the terminal site to the adjacent Hunt Creek estuary. The area is currently vegetated with a narrow band of cottonwood trees (part of which is proposed for removal) as well as scrub-shrub and emergent wetland vegetation. Installation of trees within this buffer would provide a visual screen from the terminal site to the adjacent Hunt Creek estuary and would provide habitat for fish and wildlife species.

Following construction, NorthernStar's railroad right-of-way revegetation plan would result in the installation of native vegetation within the realigned railroad right-of-way. The right-of-way would consist of a 100-foot corridor centered on the tracks. A 30- to 40-foot wide strip, centered on the tracks, would be left unvegetated to allow for visibility. The portion of the right-of-way on the north side of the tracks would consist of a concrete facility berm and would not be revegetated. Along the southern side of the tracks, vegetation would be installed in a 30- to 35-foot-wide planting zone which would extend the length of the proposed rail alignment. NorthernStar's railroad right-of-way revegetation plan consists of two vegetative zones. The width of the zones would be variable, depending on the distance from the railroad tracks to Hunt Creek. The majority of the planting zone would be vegetated with low-growing herbaceous species in order to maximize visibility and minimize fire fuel. Low-growing herbaceous species, including lupine species and native grass species, would have a mature height less than 5 feet. Where the railroad right-of-way approaches Hunt Creek, near the center of the rail realignment, upland shrubs would be installed. Upland shrubs would have a mature height of 10 feet and greater. NorthernStar intends to salvage and temporarily replant appropriate native plant species (along with native topsoil) prior to construction for site restoration and landscaping purposes after construction. NorthernStar does not anticipate that vegetative management would be required in the 30- to 35-foot area along the southern portion of the railroad right-of-way.

Maintenance throughout the LNG terminal site would consist of monitoring, removal of tree saplings within 25 feet of the security fence, and noxious weed removal. Monitoring of the site would consist of a walk-through assessment that would be scheduled to occur annually but may be conducted at any time. Additional maintenance and monitoring would be done to ensure survival and to verify that success criteria are met in areas planted for site restoration and compensatory mitigation. NorthernStar's Compensatory Mitigation Plan contains additional details regarding success criteria within mitigation sites.

As described above, NorthernStar would plant shrub and tree species with mature heights of less than 15 to 20 feet within 25 feet of the security fence; therefore, maintenance clearing in revegetated areas is not anticipated. However, in areas not cleared during construction, new tree saplings taller than 25 feet may occur within 25 feet of the security fence. These trees would be flagged for removal and would be topped, rather than grubbed, to allow for development of snags.

With the exception of areas within 25 feet of the security fence, riparian areas outside of the berm would be allowed to permanently revegetate in order to retain riparian function. Areas in need of noxious or invasive species removal would be flagged or marked. Noxious or invasive species would be removed in order to ensure that success criteria of installed native plant communities are met. Populations of noxious weeds and invasive non-native vegetation determined to significantly affect the installed

vegetation would be removed by hand, ensuring that native vegetation is not disturbed. The most effective method for managing some invasive species is manual removal of the entire plant, including its root mass. Removal would occur as soon as possible, before the invasive species goes to seed or develops a substantial root mass, which could increase the effort necessary to remove the plants. NorthernStar has committed to bagging invasive species in plastic and disposing them off site at a permitted landfill. Noxious weeds and other invasive plant species are discussed in detail in section 4.4.2.3.

Since the issuance of the draft EIS, NorthernStar has proposed modifications to Bradwood and Clifton Roads and has revised the proposed location for a construction worker parking lot. NorthernStar has not submitted information to the FERC regarding vegetation or other resource impacts at these locations. Therefore we recommended in section 4.2.2.1 that NorthernStar quantify and file impacts on vegetative communities associated with the modifications to Bradwood and Clifton Roads as well as the new proposed construction worker parking lot prior to construction.

Electric Power Line

Additional impacts on vegetation would occur as a result of construction of the electric power line. Clearing within the 100-foot-wide right-of-way would impact about 17.8 acres of vegetation. Included in this would be 8.6 acres of coniferous forest, 5.6 acres of early seral forest, 3.5 acres of deciduous forest, and 0.1 acre of scrub-shrub. Following construction, the affected area would be replanted with native trees and shrubs and allowed to revegetate. A 15-foot-wide area adjacent to either side of the transmission line would be maintained by PacifiCorp in a grassland/herbaceous cover type, which would result in the permanent conversion of 5.0 acres of forested land (2.4 acres of coniferous forest, 1.6 acres of early seral forest, and 1.0 acre of deciduous forest) to a grassland/herbaceous cover type. As part of their scheduled maintenance, PacifiCorp would also remove trees from within the 100-foot-wide permanent right-of-way that are dead, dying, diseased, deformed, or unstable and that have a high probability of falling.

4.4.2.3 Pipeline Facilities

Existing Upland Vegetation

Table 4.4.2-1 lists the upland vegetative communities present along the proposed pipeline route. Dominant and understory species composition within each of these communities is provided in section 4.4.2. Agriculture and coniferous forests are the most common vegetative communities along the proposed pipeline route, comprising 98.6 acres and 76.2 acres of land affected, respectively. Agricultural vegetative communities occur throughout the areas crossed by the proposed pipeline route and are often characterized by regular landscape patterns and straight borders due to ownership boundaries and multiple crops within a region. This community is diverse and includes several cover types ranging from low-stature annual grasses and row crops less than 3 feet tall at maturity to mature tree farms greater than 60 feet in height. Structural diversity within each cover type (crop) is low. Depending upon management intensity or cultivation method, agricultural communities may vary substantially in structure on an annual basis. Herbaceous agricultural fields and pastures are found scattered along the proposed pipeline route and are closely associated with roads, residential developments, and sometimes industrial developments. Deciduous cottonwood/poplar (*Populus* spp.) farms and coniferous Douglas-fir tree farms are also found along the pipeline route, usually in less-developed areas.

Coniferous forests also occur throughout the proposed pipeline route. The majority of coniferous forests are comprised primarily of trees between 20 and 80 years old that have been planted for commercial timber. However, a narrow band of old-growth coniferous forest occurs parallel to the

Columbia River within the far western portion of the pipeline route near the LNG terminal. These stands are characterized by mature Douglas-fir, with lesser amounts of mature western hemlock and western red cedar. The canopy is fairly open in places due to the presence of large snags as well as a steep basalt bluff that separates the forest from the Columbia River below. Dominant or co-dominant understory species in coniferous forest typically include hemlock and cedar saplings, vine maple, salal, dwarf Oregon grape (*Mahonia nervosa*), elderberry, swordfern, and the invasive Himalayan blackberry. Other forbs and ferns that frequently dominate the understory are bracken fern (*Pteridium aquilinum*), ladyfern, youth-on-age, and stinging nettle.

General Impacts and Mitigation

Pipeline Right-of-way

The primary impact from the pipeline and associated aboveground facilities on vegetative communities would be the cutting, clearing, and/or removal of existing vegetation within the construction work area. The degree of impact would depend on the type and amount of vegetation affected, the rate at which the vegetation would regenerate after construction, and the frequency of vegetation maintenance conducted during operation of the project. The swath of vegetation that would be disturbed during construction would be either 100 or 120 feet wide in upland areas, depending on whether topsoil segregation is required, with the exception of areas crossed using the HDD method. Absent unforeseen events such as inadvertent returns of drilling mud (see section 4.3.2.4), the only potential disturbance in areas crossed using the HDD method would be minor trimming of vegetation using hand tools directly over the pipeline. This minor clearing is required to facilitate the temporary deployment of HDD guidance (telemetry) cables along the ground during construction and to perform a leakage survey after installation and commissioning.

Secondary effects associated with disturbances to upland vegetation could include increased soil erosion (see section 4.2.3.2), increased potential for the introduction and establishment of invasive weedy species (see *Noxious Weeds and Other Invasive Plant Species* below), and a local reduction in available wildlife habitat (see section 4.5.3.3).

To reduce impacts on vegetation within the construction and permanent rights-of-way and improve revegetation potential, NorthernStar would implement its pipeline ESC Plan in Oregon and SWPPP in Washington as well as our Procedures. Following construction, all work areas would be restored, seeded with conservation grasses, legumes, native plant species, or other standard erosion control/cover species, where required, and allowed to naturally revegetate to preconstruction conditions, with the exception of upland forested communities which would be replanted in-kind with trees. The permanent right-of-way would generally be maintained in an herbaceous state following construction. NorthernStar would monitor the success of revegetation efforts and employ reseeding, fertilizing, and other measures until herbaceous vegetative cover and density are similar to the adjacent areas not disturbed by construction. If there are excessive noxious weeds after the first or second growing season, an agronomist would determine the need for additional restoration measures that NorthernStar would implement, as necessary.

NorthernStar's proposed construction right-of-way, temporary extra work areas, and access roads associated with the pipeline would disturb a total of about 328.5 acres of upland vegetation. As described above, NorthernStar would avoid impacts on about 178 acres of upland vegetation by using the HDD method to install the pipeline underneath old-growth coniferous forest and some roads. As described in table 4.4.2-1, the most common vegetative communities occurring along the proposed route are agricultural (98.6 acres), coniferous forest (76.2 acres), and mixed forest (52.2 acres), which account for nearly 70 percent of the vegetation that would be cleared or affected by construction. The next most

common cover types that would be affected are developed areas (42.7 acres) and deciduous forest (32.1 acres).

Agricultural communities would typically regenerate quickly after cleanup and reseeded of the right-of-way. Cultivated areas are regularly disturbed, generally receive ample water through irrigation if necessary, and would quickly reestablish on the right-of-way following replanting by the landowners; however, a small portion of the agricultural cover type (about 4.2 acres) also includes perennial crops associated with orchards, vineyards, tree plantations, and plant nurseries. Impacts on these perennial crops would be long term because of the time needed to establish the crops and, in some cases (i.e., orchards and tree plantations), the impacts would be permanent if the crop is restricted from being grown over the permanent easement. Vegetation would be replanted within the temporary construction right-of-way immediately after construction as part of site-specific plans and agreements with landowners, except large trees and shrubs, which, due to availability, may not be replaceable with specimens of comparable size. Additional information about impacts on and potential mitigation measures for residential areas, including landscaping, is presented in section 4.7.3.3.

Longer-term impacts would occur on upland scrub-shrub communities because these areas would be reseeded only with conservation grasses, legumes, native herbaceous species, or other standard erosion control/cover species, where required, and the shrub species that would recolonize the right-of-way from adjacent areas would require several years to reestablish their woody canopy. Permanent impacts would occur on the scrub-shrub community that is currently present within the permanent easement because the species would not be allowed to regenerate the woody canopy present before construction due to periodic right-of-way maintenance activities. Maintenance of the entire right-of-way would occur no more than once every 3 years. However, to facilitate maintenance and inspection, NorthernStar may clear a 10-foot-wide corridor centered on the pipeline annually.

Similar to scrub-shrub communities, impacts on forested communities (i.e., coniferous, deciduous, mixed, early seral, and riparian forests) would be considered long term because of the time required to restore the woody vegetation to its preconstruction condition. Impacts associated with construction and operation would be greatest on these cover types due to the change in structure and environment caused by the removal of the large tree canopy over the width of the construction right-of-way. The clearing of trees from the construction right-of-way could also affect the remaining trees along the edge of the right-of-way. Trees located on the edge of the right-of-way may be subject to mechanical damage to trunks and branches and root impacts from soil disturbance and compaction, all of which may result in the decreased health and viability of the remaining edge trees. Edge trees that were located within a dense stand of trees before construction may lack stability following removal of adjacent supporting trees, which may result in increased tree failures.

During construction, woody vegetation that has been cleared from the construction workspace would remain within the right-of-way until restoration commences. Woody vegetation would generally be ground in a tub grinder and spread onto the right-of-way as mulch. In areas where timber would be harvested, the trees would be cut and stacked for commercial sale. The logs would be hauled to market and the proceeds of the sale collected by the property owner. NorthernStar has made an agreement with the WDFW regarding the use of certain trees cut down during pipeline construction in Washington. Based on a protocol provided by the WDFW, certain trees would be hauled to a storage area to be utilized as the start of a LWD bank for the State of Washington. Other trees would be used to meet mitigation requirements. No trees, slash, or woody vegetation would be burned during construction of this project.

In upland forested areas, permanent impacts would be greatest over the maintained portion of the right-of-way, totaling about 54 acres. Upland forested communities would be replanted in-kind with trees, with the exception of the portion of the right-of-way within 15 feet of the pipeline (30 feet total),

thereby minimizing the extent of disturbance. NorthernStar's proposed tree planting exceeds the revegetation requirements of the FERC staff's Plan and Procedures. The 30-foot-wide corridor centered on the pipeline would be planted with a native grass seed mix and maintained in an herbaceous state to facilitate maintenance and inspection. As described above for upland scrub-shrub communities, annual clearing for maintenance of the pipeline in forested communities would be limited to the 10-foot corridor centered on the pipeline. Nearly complete canopy coverage over the pipeline would be expected to develop in most areas within approximately 20 years.

Adjacent to waterbodies, a riparian strip at least 25 feet wide, as measured from the waterbody's MHW mark, would be allowed to permanently revegetate with native plant species across the entire right-of-way. As described above, trees greater than 15 feet tall, or deep-rooted shrubs that could damage the pipeline's protective coating, obscure periodic surveillance, or interfere with potential repairs, would not be allowed to grow within 15 feet (30 feet total) of the pipeline.

Vegetation Communities of Special Concern or Value

As described above, the WDFW has identified and mapped 18 Priority Habitats. Vegetation communities of special concern were not specifically identified in Oregon. However, NorthernStar would mitigate for impacts on habitats of varying quality by complying with ODFW's HMP (see section 4.5.2.4).

About 1.8 acres of riparian Priority Habitat would be affected by construction of the Bradwood Landing pipeline in Washington. Of this, about 0.9 acre would be permanently maintained in an herbaceous state. Similar to other forested cover types, impacts on riparian forest would be considered long term because of the time required to restore the habitat to its preconstruction condition. To reduce impacts on riparian vegetation within the construction and permanent rights-of-way, NorthernStar would implement the measures included in its pipeline ESC Plan and SWPPP, as well as utilize the HDD or bore methods at up to 23 waterbody crossings (see section 4.3.2.4). NorthernStar would reduce the size of waterbody crossing staging areas and place these staging areas at least 50 feet from the water's edge whenever topographic conditions permit. Additionally, NorthernStar would allow a riparian buffer at least 25 feet wide, as measured from the waterbody's MHHW mark, to permanently revegetate with native woody plant species across the entire right-of-way; however trees greater than 15 feet tall, or deep-rooted shrubs that could damage the pipeline's protective coating, obscure periodic surveillance, or interfere with potential repairs, would not be allowed to grow within 15 feet (30 feet total) of the pipeline.

Noxious Weeds and Other Invasive Plant Species

Noxious weeds and other invasive plant species are non-native, undesirable native, or introduced species that are able to exclude and out-compete desirable native species, and thereby decrease overall species diversity. Noxious weeds often invade and persist in areas after the vegetation and ground have been disturbed and can hinder restoration.

The Oregon Department of Agriculture has developed the Noxious Weed Control Program. A part of the program's goals are to rate and classify weeds at the state level; to prevent the establishment and spread of noxious weeds; and to encourage and implement the control, containment, or eradication of infestations of designated weed species. The Noxious Weed Control Program places weeds on either "A" or "B" lists in order to prioritize and implement noxious weed control projects. "A" designated weeds either occur in the state in small enough infestations to make eradication or containment possible or are not known to occur, but their presence in neighboring states make future occurrence in Oregon seem imminent. The Oregon Department of Agriculture recommends eradication or intensive control when and where these weeds are found. "B" designated weeds are regionally abundant but may have limited

distribution in some counties. The Oregon Department of Agriculture recommends limited to intensive control at the state, county, or regional level as determined on a case-by-case basis. In addition, the Oregon Department of Agriculture annually develops a target list of weed species that will be the focus for prevention and control by the Noxious Weed Control Program, sanctioned by the Oregon State Weed Board. These weeds are “T” designated and are species selected from either the “A” or “B” lists.

Similarly, Washington has noxious weed laws that require counties and/or local weed districts to develop and oversee local weed management programs to control the spread of noxious weeds according to state laws. The Washington State Noxious Weed Control Board determines which plants are placed on the Washington State Noxious Weed List. Noxious weeds in Washington are placed into one of three categories. Class A weeds are non-native species with a limited distribution in the state and require eradication by state law. Class B weeds are species established in some regions of Washington but are of limited distribution or not present in other regions of the state, and treatment requirements vary between the different regions. Class C weeds are species already widely established in Washington or are of special interest to the state's agricultural industry. Control of Class C weeds may be required if desired by the county.

Biologists conducting field surveys for NorthernStar identified several species of noxious weeds occurring within the project area, including Scotch broom, Himalayan blackberry, reed canary-grass, and purple loosestrife. NorthernStar would consult with the Oregon and Washington Departments of Agriculture and other appropriate agencies to determine the location of other noxious weeds and whether soil-borne plant diseases of significance to agricultural productivity have been identified in the project area. To prevent and mitigate for the distribution of noxious weeds during construction and control noxious weeds that develop after construction, NorthernStar has agreed to implement the following measures, as described in its *Noxious Weeds and Soil-borne Plant Disease Control Plan*:¹²

- Contractors would be required to thoroughly clean each unit of construction equipment with high-pressure washing before the initial move of those units of construction equipment to the general construction site.
- Reasonable efforts would be made to obtain straw bales for erosion control and straw for mulch that are free of noxious and nuisance weed contamination.
- Where additional soil is necessary to restore the original soil contours as a result of the removal of excess rock from the trench backfill, imported soil would be used. NorthernStar would make reasonable efforts to obtain imported soil that is free of noxious weeds.
- When available, Oregon or Washington certified seed or equivalent would be used for revegetation.
- NorthernStar would monitor the revegetation of non-cultivated areas the first and second year after construction. Non-cultivated areas where seedling establishment has failed would be reseeded during the next appropriate seeding period. The revegetation of the construction area would be considered successful when, based on visual observation, the density or cover of well established, herbaceous, non-nuisance vegetation in the construction area is similar to the density or cover of herbaceous vegetation in adjacent

¹² NorthernStar included its *Noxious Weeds and Soil-borne Plant Disease Control Plan* as part of its JPA. NorthernStar filed its JPA with the FERC on November 22, 2006, and filed revisions to the JPA on April 5, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

areas not disturbed by construction. If the herbaceous vegetative cover or density in the construction area is not similar to that in adjacent areas not disturbed by construction, or if there are excessive noxious weeds after the first or second growing season, an agronomist would determine the need for additional restoration measures. NorthernStar would implement additional restoration or mitigation measures, as necessary.

On permanent right-of-way areas where NorthernStar has control of the surface use of the land such as aboveground valve sites and metering stations, weed control would be conducted in a manner that would prevent the spread of weeds to adjacent lands used for agriculture. Herbicide application on such areas would be conducted by an applicator licensed by the State of Oregon or Washington in accordance with our Procedures. Generally, herbicides would only be applied in the space directly over the pipeline and would target only the woody species, leaving the grasses intact to provide stability to the soils, and are applied during the dry part of the growing season when leaves are fully emerged. Herbicide application and other vegetation control near streams would be performed with hand tools. In accordance with our Procedures, herbicides would not be applied within 100 feet of any waterbody, including waterbodies containing federally listed species, designated critical habitat, or EFH.

The FERC received numerous comments relating to the adequacy of NorthernStar's *Noxious Weeds and Soil-borne Plant Disease Control Plan*. In its December 19, 2007 letter, the EPA stated that weed control methods proposed by NorthernStar should be identified. In its December 21, 2007 letter, the U.S. Department of the Interior recommended that all construction equipment be power-washed at a self-contained site before being transported to and/or from the construction right-of-way. Commentors also recommended that clean straw bales and fill be required for erosion control and that Oregon or Washington certified seed or equivalent be required for all revegetation. In addition, the NMFS has requested that specific information on the methods proposed and timing of noxious weed control be submitted as part of the revised BA and EFH Assessment. Therefore, **we recommend that:**

- **NorthernStar should continue to consult with the COE, FWS, NMFS, Oregon and Washington Departments of Agriculture, and other appropriate resource agencies to revise its *Noxious Weeds and Soil-borne Plant Disease Control Plan*. NorthernStar should file the final *Noxious Weeds and Soil-borne Disease Control Plan* along with agency comments on the plan with the Secretary within 30 days after the issuance of the final EIS.**

4.5 WILDLIFE AND AQUATIC RESOURCES

4.5.1 Waterway for LNG Marine Traffic

4.5.1.1 Aquatic Resources

The Columbia River is a highly productive biological environment that is influenced by a variety of complex physical processes. The major short-term processes affecting the area include tides and, secondly, local winds and currents. River flow also has a major seasonal impact, the extent of which depends on the volume of water from snow melt.

Existing Aquatic Resources

Marine Fish

The Columbia River, the estuary, and the offshore waters of the Pacific Ocean provide habitat for a variety of anadromous and resident fish species. Anadromous fish are present in the river throughout the year as adults migrating upstream to spawn, as juveniles rearing in the river and its tributaries, and as juveniles migrating downstream to the ocean. Anadromous salmonids occurring within or near the proposed project area include: Chinook, coho, sockeye, and chum salmon; steelhead; and coastal cutthroat trout. Of these, 13 ESU/DPSs are federally listed and are discussed in sections 4.6.1.1 and 4.6.2. In addition, EFH has been designated for Chinook and coho salmon along the waterway as discussed in section 4.5.1.2. Other anadromous and marine species include green and white sturgeon, eulachon, shad, striped bass, starry flounder, three spine sticklebacks, pea mouth, and Pacific and river lampreys.

Marine fish are present both in the Pacific Ocean and in the estuary of the Columbia River. Estuaries are protected nearshore areas such as bays, sounds, inlets, and river mouths, influenced by both ocean and freshwater. Because of tidal cycles and freshwater runoff, salinity varies within estuaries and results in great diversity, offering freshwater, brackish, and marine habitats within close proximity. Estuaries tend to be shallow, protected, nutrient rich, and are biologically productive, providing important habitat for marine organisms. As discussed in detail in section 4.5.1.2., EFH is defined as those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity and has been designated within the Zones of Concern for more than 90 species of groundfish, 5 species of coastal pelagic species, 2 species of salmon, and 13 highly migratory species.

Larval and juvenile marine fish comprise a significant portion of the offshore planktonic communities. Smelt, tomcod, right-eye flounder, and anchovy are commonly found in the offshore communities during the winter and spring. Marine species that enter the estuary are generally confined to the deeper channels where salinity is high. Some species, in particular juveniles of these species, are more tolerant of lower salinity and can be found farther upriver and in the shallower areas associated with the bays. Bays are generally more productive than channel areas and provide feeding and rearing habitat for many marine species. Demersal fish (living near the bottom) are attracted to the bays for this reason. However, demersal fish can also be attracted to channel areas during seasonal periods with abundant benthic and epibenthic species. Pelagic fish (living in surface water to middle depths) are most likely to be found in areas rich in plankton. Fish most often found in the deeper channels of the estuary are white sturgeon, Pacific herring, shad, and surf smelt. Some marine species, such as Pacific herring, use the estuary as a spawning area (COE, 1999).

The estuary also serves as a nursery and rearing area for some species of marine fish, including Pacific tomcod, surfperch, rockfish, sanddabs, smelt, and starry flounder. These species are generally confined to the lower estuary where salinity is higher. However, English sole and Pacific staghorn

sculpin are somewhat tolerant of freshwater and occur as far upriver as Tongue Point. Similarly, starry flounder are known to occur as far upriver as Portland.

The lower Columbia River population of white sturgeon is the largest in the species range, due primarily to access to marine areas, abundant food resources, and consistently favorable hydrologic conditions during the spawning period (DeVore et al., 1995). White sturgeon occur throughout the lower estuary and river during all life history stages. Spawning occurs primarily in the deeper areas just below Bonneville Dam, though spawning is also known to occur in deepwater areas of the lower river. Spawning lasts for 38 to 48 days from late April or early May through June or July. Growth is rapid during the first summer, with young-of-the-year reaching a length of 7 inches by the end of September. Young-of-the-year and juvenile sturgeon are usually found in water deeper than 36 feet (McCabe and Tracy, 1994).

Freshwater Fish

Resident freshwater fish within the lower Columbia River include both coldwater (trout) and warmwater (bass, crappie, and bluegill) species. Fies (1971) conducted gill net surveys within the sloughs of the lower Columbia River to assess the stock of warmwater game fishes. The data from his study indicates that there are at least 16 non-salmonid species commonly occurring within the slough and lower floodplain reaches of streams within the subbasin. Five of these 16 species are native fish and the others are exotic or introduced species.

Several of the exotic fishes are predators of small fish and pose a threat to migrating juvenile salmonids. Northern pikeminnows (a native fish of the Columbia River), white crappie, black crappie, and largemouth bass are all predators and found within the sloughs and floodplain habitats of the Lower Columbia River Subbasin (Fies, 1971).

Fies (1971) found yellow bullhead to be abundant. Other exotic fish may compete with native fish for habitat or food, reducing growth rates of native fish and potentially decreasing survival. A few representative non-ESA listed species, known to occupy the basins and waterbodies containing federally listed salmonids in the project area are discussed in *Commercial and Recreational Fisheries*.

Marine Mammals

Thirty-one species of marine mammals have been recorded within the Northeastern Pacific Ocean, including 7 species of baleen whales; 17 species of toothed whales, dolphins, and porpoises; 5 species of pinnipeds (seals and sea lions); and sea otters (Carretta et al., 2006). Large numbers of Steller sea lions, California sea lions, and Pacific harbor seals can be found utilizing haulout sites along the lower Columbia River. Maps depicting the locations of haulout sites used by Steller sea lions and seals are included in Appendix C. Steller sea lions are federally and state-listed and are discussed in sections 4.6.1.1 and 4.6.2. Eight species of federally and state-listed whales potentially occur off the coasts of Oregon and Washington and are discussed in sections 4.6.1.1 and 4.6.1.2. The remaining marine mammals are protected under the MMPA and are discussed in detail in sections 4.6.1.3, 4.6.2.1, and 4.6.2.2.

Sea Turtles

Four species of sea turtles have been documented off the coasts of Oregon and Washington. These include the green, olive ridley, leatherback, and loggerhead sea turtles. Sea turtles occurring off the coasts of Oregon and Washington are protected under the ESA and are discussed in sections 4.6.1.1 and 4.6.2.1.

Commercial and Recreational Fisheries

The Columbia River, estuary, and Pacific Ocean support a number of valuable commercial fisheries. Major fisheries include Dungeness crab, salmon, steelhead, white and green sturgeon, eulachon, and bottom fish. However, fishing for salmon and bottom fish has declined in the last several years because of declining stocks of these species. As a result, there has been a shift to other fisheries including crab, tuna, and halibut. Recreational fisheries occur throughout the river for salmon, steelhead, sturgeon, and a variety of warmwater game fish.

Commercial salmon fishing is done by gill net in the lower river and occurs in stages: from mid-February to early March and sometimes in May (Chinook salmon), late June (sockeye salmon), June through August (Chinook salmon), and from mid-September to mid-November (Chinook and coho salmon). Commercial fishing for steelhead is done exclusively under treaty rights by Native Americans.

Commercial sturgeon fishing was originally a by-product of the salmon gill net fishery, but has become a major fishery in its own right due to the decline of the salmon fishery. Commercial fishing for sturgeon is done by gill net in the lower Columbia River. The lower Columbia River commercial white sturgeon harvest for 2005 was 8,152 fish (ODFW and WDFW, 2005). Most of the harvest occurs in the fall, although fishing also occurs in the winter, spring, and summer months. Some sturgeon are also caught during the terminal fishery for salmon in Youngs Bay (Norman and King, 1997).

Eulachon fished commercially are used for bait in recreational sturgeon fisheries, but they are also fished commercially and recreationally as food. Mainstem river fishing is done primarily by gill net and to a lesser extent by otter trawl. Fishing in the tributaries is done with dip nets as regulated by the States of Oregon and Washington. Total eulachon landings for the mainstem Columbia River for 2006 were estimated at 13,221 pounds, significantly higher than 2005, which had the lowest annual landings on record (208 pounds) (WDFW, 2006b). Eulachon are currently a candidate for listing in Washington and are discussed further in sections 4.6.1.3 and 4.6.2.

Terminal fisheries for salmon occur in Youngs Bay and Deep River (tributary to Grays Bay) and at several locations in Cathlamet Bay in the lower river. Terminal fisheries involve rearing juvenile salmon in pens and then releasing them to the ocean. When the fish return to the pen area, fishing is allowed in the immediate area to target only returning individuals. This type of fishery was developed to provide fishing opportunities without impacting wild runs.

Recreational fishing for eulachon, sturgeon, and salmon also occurs in the lower Columbia River. Recreational fishing (or dipping) for eulachon occurs in the tributaries using a dip net. Eulachon are used both as food and as sturgeon bait. Recreational harvest records are not kept but can be as high as the commercial landings during periods of high eulachon abundance. A large sturgeon fishery occurs in the estuary in the summer when sturgeon feed on bait fish that move into the estuary. Recreational fisheries for salmon also occur in the ocean and estuary, although this fishery has declined in recent years due to declining stocks. In addition, a fishery for rock and bottom fish occurs off some jetties and piers.

Fisheries of Special Concern

Fisheries resources of special concern occurring along the LNG marine transit route include: 1) fisheries protected by tribal treaty rights; 2) federally designated EFH for coho and Chinook salmon, coastal pelagic species, groundfish, and highly migratory species; 3) species listed federally as threatened, endangered, or candidates under the ESA and their designated or proposed critical habitat; and 4) species listed as threatened or endangered by the States of Oregon or Washington. Potential impacts on tribal fisheries as a result of the proposed project are discussed in section 4.8.2.4. Potential impacts on EFH

along the marine vessel route are discussed in section 4.5.1.2. Potential impacts on listed salmonids and their critical habitat, as well as state-listed threatened and endangered species, are discussed in section 4.6.2.1.

Impacts on Aquatic Resources

LNG marine traffic during operation of the Bradwood Landing Project has the potential to impact aquatic species through fish strandings, increased shoreline erosion, introduction of exotic species, vessel strikes, and releases of LNG. Much of the impact discussion included below applies to fish protected under the ESA, which are described in detail in section 4.6.1.1 and 4.6.2.1, and to EFH designated under the MSA, which is discussed further in section 4.5.1.2. In addition, marine mammals and sea turtles occurring along the waterway for LNG marine traffic are protected under the ESA and/or the MMPA and are described in sections 4.6.1.1 and 4.6.1.3.

Fish Strandings

A series of studies conducted on the lower Columbia River suggest that under certain conditions, deep-draft vessels can produce wakes that strand juvenile fish (Bauersfeld, 1977; Hinton and Emmett, 1994; Ackerman, 2002; Pearson et al., 2006; Entrix, 2008). Stranding can occur when fish become caught in a vessel's wake. The fish are then deposited on shore by the wave generated by the vessel wake. Stranding typically results in mortality unless another wave carries the fish back into the water. The most recent and comprehensive study on wake strandings on the lower Columbia River prepared by Pearson et al. (2006) suggests that the specific mechanisms of strandings are still not completely understood. It appears that no single factor controls fish strandings. Rather, a series of interlinked factors act together to produce stranding during a ship passage. These factors include:

- River-surface elevation – low tides are generally more likely to result in strandings than high tides.
- Beach slope – low-gradient beaches are generally more likely stranding locations than high-gradient ones.
- Wake characteristics – ship wakes that result in both the greatest drawn-down and run-up on the beach are generally most likely to result in strandings. Wake characteristics are influenced by a number of dynamics including vessel size and hull form (“short and fat” vessels have a greater displacement effect and generate larger wakes than “long and thin” vessels); vessel draught (the smaller the under-keel clearance, the larger the wakes; thus, loaded vessels are more likely to result in strandings than unloaded vessels); vessel speed (fast moving vessels generate larger wakes than slow vessels); the distance between the passing vessel and the beach (strandings are generally more likely at beaches close to the shipping channel than more distant beaches). Fish strandings were observed as a result of four types of vessel passages including: oil tankers, container ships, car carriers, and bulk carriers (in order of the vessels observed to cause the highest to lowest stranding frequency).
- Various biological factors – for example, the larger number of sub-yearling salmon that are present near the shoreline, the more fish that are likely to be stranded; salmon that are larger and relatively strong swimmers are generally less prone to stranding.

All of these factors can vary simultaneously, making it difficult to predict the location and to what degree strandings may occur. It is important to note that not all ship wakes strand fish. The Pearson

et al. (2006) study examined the statistical probability of strandings associated with deep-draft vessels transiting the lower Columbia River as part of the review of the Columbia River Channel Improvement Project. Pearson et al. (2006) specifically chose beaches along the lower Columbia River based on the following characteristics:

- all sites are known to have previously had juvenile salmon stranding (Bauersfeld, 1977);
- all sites have a gently sloping beach (previous work indicated that these beaches are prone to fish strandings);
- all beaches are exposed to ship wakes from the navigation channel; and
- all sites have evidence of fairly stable beach morphology.

The study looked at 126 vessel passages in three locations (County Line Park at CRM 51, Barlow Point at CRM 62, and Sauvie Island at CRM 97).

The three sites chosen for the Pearson et al. (2006) study are located upstream of Bradwood and the portion of the river LNG carriers would transit to the proposed LNG terminal. Reported strandings are greater upriver of the proposed LNG terminal compared to down river. Stranding events occurred in 46 of the 126 vessel passages observed. Of the fish that were stranded, the smaller fish of a cohort group tended to strand at a greater rate than larger fish from the same cohort group (Ackerman, 2002; Pearson et al., 2006). There is only one record of wake stranding (on Tenasillahe Island at about CRM 37) in the portion of the river downstream of the proposed LNG terminal site. There appear to be important differences in the lowermost 38 miles of the Columbia River compared with the portions of the river above the proposed LNG terminal site. The lower part of the river is broader and distances from the navigation channel to beaches are generally greater than in the upriver segment. The sampled densities of juvenile salmon are lower in the lower Columbia River shallows. Further, the effects of tides, currents, and winds may be more variable in the lower Columbia River.

Recognizing the limitations of the Pearson et al. (2006) stranding model for estimating stranding at sites other than the three beaches where the model was calibrated, Entrix (2008) developed a process model to identify regionally significant risk factors for stranding. Entrix (2008) then used bathymetric, aerial photographic, and other data sources to determine which beaches have the necessary risk factors.

Six risk factors for wake stranding were identified by the Entrix (2008) study:

- A confined channel – The type of long-period waves that have been observed to strand fish do not develop in unconfined channels.
- Distance from sailing line – Stranding has previously been encountered along the lower Columbia River on beaches up to 853 feet from the edge of the ship channel.
- Shielding features – Stranding is not observed on beaches that lack a “line of sight” to the navigational channel, so such beaches are presumably not at risk for stranding. Stranding risk is assumed to be low if a “line of sight” exists, but an intervening sand bar or the flows of a major tributary stream would disrupt the passage of a ship wake.
- Beach slope – Stranding is most often observed on beaches that have a very low slope. Stranding risk was assessed as high on beaches with a slope less than 2.5 percent, moderate on beaches with a 2.5 to 5 percent slope, low on beaches with a 5 to 10 percent slope, and minimal on beaches with a steeper slope.

- Presence of a berm – A berm is a break in bottom slope such that a shallow-water shelf exists offshore of the beach. Ship wakes propagate very effectively where there is a berm in water less than 18 feet deep, so much so that the presence of a berm is nearly a prerequisite for stranding to occur. Stranding risk increases as the berm becomes shallower; a high risk exists for berms less than 6 feet deep (CRD), a moderate risk exists for berms 6 to 12 feet deep, and a low risk exists for berms 12 to 18 feet deep.
- Fine-scale beach features – Certain beach features, such as riprap or vegetation, affect stranding risk. Aerial photography was reviewed to identify the occurrence of such features.

LNG carriers transiting the lower Columbia River over the operation life of the LNG terminal are likely to result in the stranding of some sub-yearling fish. Based on reasonably available information, we are not able to predict the level of fish strandings that would be directly associated with the Bradwood Landing Project. The quantitative results on the level of fish strandings from the stranding studies conducted to date cannot be extrapolated to other areas on the Columbia River because of the study designs and the varying forces that affect the important variables from one location to another. The FERC staff continues to study this issue in consultation with the NMFS, ODFW, and WDFW. The process model developed by Entrix (2008) will be expanded upon by conducting field analysis to groundtruth berms associated with beaches designated as high risk or greater. Additionally, a model will be developed to generate estimates of the number of fish expected to be impacted by LNG carrier activities. The new model will build from the Entrix (2008) process model described above by incorporating potential stranding risk, LNG carrier frequency and timing, juvenile salmonid run timing, and juvenile salmonid densities. These additional analyses regarding wake stranding effects on fish will be included in the revised BA and EFH Assessment.

Shoreline Erosion and Prop Wash

Prop wash from LNG carriers associated with the project, as well as ship wakes breaking on shore could cause increased erosion along the shoreline and resuspend the eroded material within the water column. Increased erosion and suspended sediment levels can adversely affect fish eggs and fish survival, benthic community diversity and health, and spawning habitat. At high concentrations, suspended sediments can affect oxygen exchange over the gills, resulting in weakened individuals or mortality.

Numerous comments were received on the draft EIS regarding the potential impacts on aquatic resources due to increased erosion and suspended sediment levels within the Columbia River. As described in section 4.1.2.3, LNG carrier wakes and tug propeller wash could impact shorelines along the route and contribute to erosion at a number of locations where the channel is narrow relative to vessel size, vessel speed remains high, shorelines are in close proximity to the sailing line, and banks already have suffered erosion from similar causes. Additional analysis of the potential impacts on salmonids from increased shoreline erosion due to LNG carrier wakes will be included in the revised BA and EFH Assessment. To minimize the potential for impacts on aquatic resources due to LNG carrier transit, **we recommend that:**

- **NorthernStar should coordinate with the NMFS to determine appropriate LNG carrier speed, or other applicable measures, to avoid or minimize impacts on juvenile fish from wake stranding and shoreline erosion due to LNG carrier transit along the waterway. Results of modeling and coordination, including any specific measures to be implemented, should be filed with the Secretary, within 30 days after issuance of the final EIS.**

Introduction of Exotic Species

LNG carriers in transit to and from the LNG terminal could import exotic species on their hulls and exterior equipment. The LNG carriers would come from the other side of the Pacific Ocean on a voyage taking approximately 3 weeks. Operators of commercial vessels have a significant economic interest in maintaining underwater body hull platings in a clean condition. Fouling of bottom platings would result in increased fuel costs for voyages and could also reduce the vessel's maximum transit speed. To prevent fouling and the associated economic costs, operators aggressively and conscientiously apply hull plating preservation and maintenance programs. Furthermore, failure to preserve and maintain hull plating not only raises short-term operation costs but also sets the stage for increased long-term hull maintenance costs. There is a particular sensitivity to this engineering and economic reality regarding commercial vessels operating at the higher end of the sailing rates schedule, as is the case for LNG carriers.

In addition to the antifouling program measures, fluid dynamics plays a practical role as a barrier to the introduction of invasive species in the manner described. The amount of water that passes over the hull and through the seachest is a massively large volume. The velocity of the seawater, abrasive by nature, along the hull would be expected to "waterblast" off anything that is not affixed to the hull (e.g., a barnacle). Normal ballast exchange requires only three changes of water through the ballast tanks to purge out any loading port organisms before arrival at the unloading port. These exchanges are done at sea and the exchanges occur at relatively low velocity. By contrast, the hull and seachest would have the equivalent of untold multiples of seawater exchange such that an organism on the hull or in the seachest would be flushed off with much more velocity and volume of water than the accepted international ballast exchange procedure.

The Coast Guard has developed responses to exotic/invasive organisms associated with foreign vessels. The Coast Guard Office of Operating and Environmental Standards developed *Mandatory Practices for All Vessels with Ballast Tanks on All Waters of the United States*. The mandatory practices include requirements to rinse anchors and anchor chains during retrieval to remove organisms and sediments at their place of origin and remove fouling organisms from hull, piping, and tanks on a regular basis and dispose of any removed substances in accordance with local, state, and federal regulations.

In addition, ships must have onboard and adhere to a Ballast Water Management Plan and must maintain a Ballast Water Record Book to record the intake and discharge of ballast water (IMO, 2004). As part of the International Convention for the Control and Management of Ships' Ballast Water and Sediments, the IMO may institute more stringent requirements for the control of invasive organisms in ballast water, provided the convention is ratified by at least 30 member states (only 8 have currently ratified it). Under the 2004 convention, all ships with ballast water capacity more than 5,000 m³ (which would include all LNG carriers) would be required to follow Ballast Water Exchange and/or Performance Standards, which include testing to demonstrate that potentially harmful organisms either are not present or are present in very small quantities. On September 2006, a federal district court ruled that by September 30, 2008, the EPA needs to take specific action to ensure that shipping companies comply with the intent of the CWA and restrict the discharge of ballast water into United States waters (Buck, 2006). While EPA has not developed specific actions, operation of the proposed project would be required to comply with any future EPA discharge requirements.

Based on above descriptions of hull plating surface treatments, the fluid dynamics along the LNG carrier's underwater body, and mandatory practices required by the Coast Guard and IMO, LNG carriers would not likely introduce exotic or invasive species into the lower Columbia River system.

Vessel Strikes

The addition of 125 vessel trips per year on the Columbia River and off the coasts of Oregon and Washington has the potential to result in collisions between LNG carriers and sea turtles and/or marine mammals. Although sea turtles and whales would not likely occur in the immediate vicinity of the LNG terminal, they could be affected by vessels transiting from areas located throughout the Pacific Basin. The potential for vessel strikes to affect sea turtles and/or marine mammals is discussed in detail in section 4.6.2.1. The potential also exists for vessel strikes to pinnipeds, as further discussed in section 4.6.2.1.

Release of LNG or Fuel

The potential exists for an LNG spill and associated fire during transit of the LNG carriers to the LNG terminal that could affect aquatic species occurring in the immediate vicinity of the spill. As described in section 4.11.5.3, the released LNG would vaporize rapidly upon contact with the air and water. Because LNG is not soluble in water and the LNG would completely vaporize shortly after being spilled, there would be no liquid left that could mix and/or contaminate the water. However, the greatest threat to aquatic species from an LNG spill would be thermal stress from the rapid change in water temperature due to contact with the cryogenic liquid (before the LNG vaporizes) or the fire associated with the ignited vapors. Any aquatic species in the immediate vicinity of the LNG or the fire would probably experience a sudden thermal shock that would be lethal. Aquatic species in the general area of a spill would most likely detect the temperature change and avoid the area. With implementation of the mitigation measures described in the Coast Guard's WSR (Appendix G), an LNG release would be highly unlikely, and therefore, the potential impacts on aquatic resources would be less than significant.

Fuel (e.g., diesel) used for vessel propulsion or auxiliary/emergency generators could potentially spill or leak. However, fuel on each ship is protected by the vessel's double hull. Furthermore, each LNG carrier would maintain a SOPEP which would contain measures to be implemented in the event of a petroleum release (see section 4.3.2.2).

4.5.1.2 Essential Fish Habitat

The MSA (Public Law 94-265 as amended through October 11, 1996) was established, along with other goals, to promote the protection of EFH in the review of projects conducted under federal permits, licenses, or other authorities that affect or have the potential to affect such habitat. EFH is defined in the MSA as those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity.

Federal agencies that authorize, fund, or undertake activities that may adversely impact EFH must consult with the NMFS. Although absolute criteria have not been established for conducting EFH consultations, the NMFS recommends consolidated EFH consultations with interagency coordination procedures required by other statutes, such as NEPA, the Fish and Wildlife Coordination Act, the ESA, and the Federal Power Act in order to reduce duplication and improve efficiency (50 CFR 600.920(e)). Generally, the EFH consultation process includes the following steps:

- 1) Notification – The action agency should clearly state the process being used for EFH consultations (e.g., incorporating EFH consultation into an EIS, section 10 permit).
- 2) EFH Assessment – The action agency should prepare an EFH Assessment that includes both identification of affected EFH and an assessment of impacts. Specifically, the EFH should include:

- a description of the proposed action;
 - an analysis of the effects (including cumulative effects) of the proposed action on EFH, the managed fish species, and major prey species;
 - the federal agency's views regarding the effects of the action on EFH; and
 - proposed mitigation, if applicable.
- 3) EFH Conservation Recommendations – After reviewing the EFH Assessment, the NMFS should provide recommendations to the action agency regarding measures that can be taken by that agency to conserve EFH.
 - 4) Agency Response – Within 30 days of receiving the recommendations, the action agency must respond to the NMFS. The action agency may notify the NMFS that a full response to the conservation recommendations will be provided by a specified completion date agreeable to all parties. The response must include a description of measures proposed by the agency to avoid, mitigate, or offset the impact of the activity on EFH.

We consolidated EFH consultations for the Bradwood Landing Project with the consultations required under the ESA. As such, we have prepared a BA and EFH Assessment for the Bradwood Landing Project and submitted it to the FWS and NMFS with a request to initiate the formal consultation process. The BA and EFH Assessment details the environmental baseline for EFH, federally listed species, and critical habitat; direct, indirect, interdependent and interrelated, and cumulative effects; proposed conservation measures; and determinations of effect. Based on comments from the FWS and NMFS, the FERC staff is currently revising the BA and EFH Assessment; upon completion, the BA and EFH Assessment will be resubmitted to the agencies with a request to initiate consultation.

Identification of Essential Fish Habitat along the Waterway for LNG Marine Traffic

EFH potentially affected by the proposed project was identified through written communication with the NMFS Portland Office (NMFS, 2006a). LNG carriers would transit from the proposed LNG terminal along the mainstem Columbia River to the mouth of the Columbia River and out to the edge of the EEZ. EFH in the Zones of Concern is shown on figure 4.5.1-1 and includes habitat for more than 90 species of groundfish, 5 species of coastal pelagic species, 2 species of salmon, and 13 highly migratory species.

Groundfish EFH

Based on the current *Fishery Management Plan* (FMP) for groundfish at the time of this writing, the overall extent of groundfish EFH for all fishery management unit species is identified as: 1) all waters and substrate within waters less than or equal to about 11,500 feet in relation to MHHW, or the upriver extent of saltwater intrusion (near Harrington Point at CRM 23); 2) seamounts in depths greater than about 11,500 feet as mapped in the EFH Assessment; and 3) areas designated as habitat areas of particular concern that are not already identified by the above criteria (PFMC, 2006a). However, the PFMC notes that these EFH designations are precautionary because they are based on the currently known maximum depth distribution of all life stages of groundfish (PFMC, 2006a).

The Pacific Coast groundfish FMP manages more than 90 species over a large and ecologically diverse area. Of these, spiny dogfish, big skate, Pacific herring, Pacific hake, black rockfish, kelp greenling, lingcod, cabezon, Pacific sanddab, butter sole, English sole, starry flounder, and sand sole are known to occur within the Columbia River estuary.

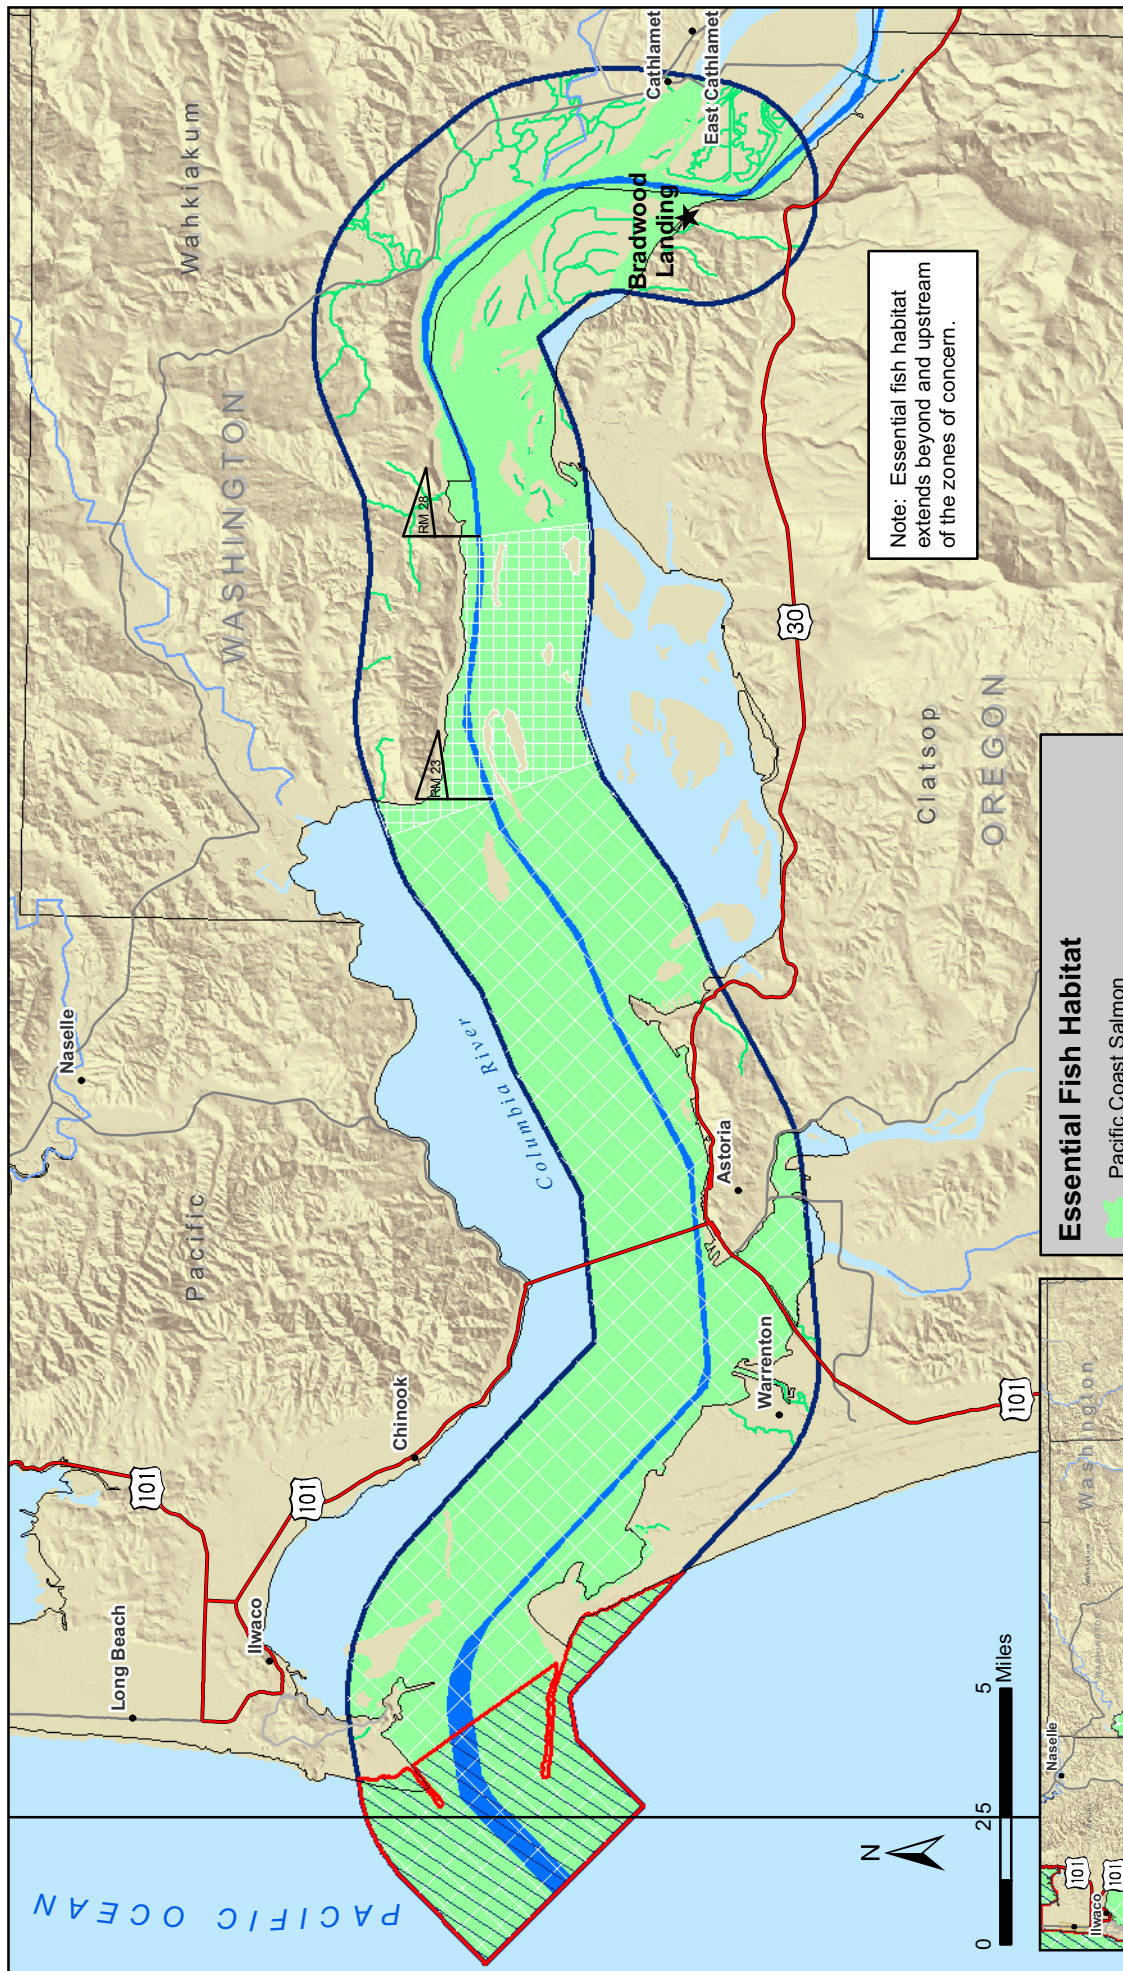

Figure 4.5.1-1
Bradwood Landing Project
Essential Fish Habitat
in Zones of Concern

Coastal Pelagic Species EFH

The EFH for coastal pelagics is defined by the species' temperature and geographic range during all life stages in the past, present, and where they could occur in the future. In addition to all marine and estuarine waters off the Pacific Coast to the limits of the EEZ, EFH for coastal pelagic species also includes portions of the water column where sea surface temperatures range between 50 °F (near the United States/Mexico maritime boundary) and 79 °F (seasonally and annually variable) (PFMC, 2006b).

The coastal pelagic species FMP includes five species: Northern anchovy, Pacific sardine, Pacific (chub) mackerel, jack mackerel, and market squid. Of these, two species (market squid and Pacific sardine) are known to occur in estuaries (PFMC, 1998).

Pacific Coast Salmon EFH

Pacific coast salmon EFH includes those waters and substrate necessary for salmon production needed to support a long-term sustainable salmon fishery and salmon contributions to a healthy ecosystem. In addition to all marine and estuarine waters off the Pacific coast to the limits of the EEZ, EFH for the Pacific coast salmon fishery includes all streams, lakes, ponds, wetlands, and other currently viable waterbodies and most habitat historically accessible to salmon. Excluded are some areas upstream of certain impassable man-made barriers (e.g., dams as identified by the PFMC in Appendix A of *Amendment 14 to the Pacific Coast Salmon Plan*), and longstanding, naturally impassable barriers (e.g., natural waterfalls in existence for several hundred years) (PFMC, 2000).

Based on available life history information, freshwater EFH for Pacific coast salmon consists of four major components:

- spawning and incubation habitats;
- juvenile rearing habitat;
- juvenile migration corridors; and
- adult migration corridors and holding habitat (Roni et al., 1999).

Important features of habitat for spawning, rearing, and migration include:

- substrate composition;
- water quality (i.e., dissolved oxygen, nutrients, temperature);
- water quantity, depth, and velocity;
- channel gradient and stability;
- food availability;
- cover and habitat complexity (e.g., LWD, pools, channel complexity, aquatic vegetation);
- space (habitat area);
- access and passage; and
- floodplain and habitat complexity.

Highly Migratory Species EFH

The EFH for highly migratory species is defined by the species' temperature and geographic range during all life stages in the past, present, and where they could occur in the future. In addition to all marine and estuarine waters off the Pacific coast to the limits of the EEZ, EFH has been designated for individual species due to their highly variable life histories. In general, species are found in temperate

waters with varying distributions and abundance based on oceanic environmental conditions including water temperature, current patterns, and the availability of prey (PFMC, 2003).

The highly migratory species FMP includes five species of tuna (north Pacific albacore, yellowfin, bigeye, skipjack, and northern bluefin), five species of shark (common thresher, pelagic thresher, bigeye thresher, shortfin mako, and blue), two billfish/swordfish (striped marlin and Pacific swordfish), and dorado (also known as dolphinfish and mahi-mahi). Five additional species (great white shark, megamouth shark, basking shark, Pacific halibut, and Pacific salmon) are included in the highly migratory species FMP for monitoring. Highly migratory species are pelagic and generally occur in the open ocean. Although they may spend part of their life cycle in nearshore waters, these species are not associated with estuaries (PFMC, 2003; PFMC, 2007).

Impacts on EFH

The PFMC (2000) identified potential sources of impacts on salmon EFH from non-fishing related activities. These include habitat modification or loss by actions that involve dredging, placement of fill, bank stabilization, removal of shoreline vegetation, waterway crossings for pipelines and conduits, removal of riparian vegetation, channel realignment, and the construction of docks and piers. In addition, construction adjacent to EFH could increase run-off of sediment, excess nutrients, chemicals, and petroleum products, all of which can adversely affect EFH (PFMC, 2006b). Potential adverse impacts on groundfish, coastal pelagic species, salmon, and highly migratory species are listed in table 4.5.1-1 and are discussed below.

TABLE 4.5.1-1 Potential Impacts on EFH Due to LNG Marine Traffic			
EFH	Description of EFH	Project Action with Potential Impacts on EFH	Determination of Effect
Coastal Pelagic Species	All marine and estuarine waters from the coast to the limits of the EEZ and above the thermocline where sea surface temperatures range between 50 °F and 79 °F.	Accidental spill or leak of hazardous materials.	Minimal adverse effect or less than substantial adverse effect on EFH (see section 4.5.1.1 for a discussion of mitigation measures).
Groundfish	Aquatic habitat from the extent of saltwater intrusion in river mouths to the boundary of the EEZ.	Accidental spill or leak of hazardous materials.	Minimal adverse effect or less than substantial adverse effect on groundfish EFH (see section 4.5.1.1 for a discussion of mitigation measures).
Pacific Coast Salmon	All streams, lakes, ponds, wetlands, and other waterbodies currently and historically accessible to salmon.	Accidental spill or leak of hazardous materials.	Substantial adverse effect on Pacific Coast salmon EFH (see section 4.5.1.1 for a discussion of mitigation measures).
Highly Migratory Species	All marine waters from the coast to the limits of the EEZ.	Accidental spill or leak of hazardous materials.	Minimal adverse effect or less than substantial adverse effect on EFH (see section 4.5.1.1 for a discussion of mitigation measures).

Source: Pacific Fishery Management Council, 2006b.

Aspects of LNG marine traffic with the potential to adversely affect designated EFH along the LNG carrier transit route would be limited to accidental spills or leaks of hazardous materials. A discussion of measures that would be implemented to avoid or minimize impacts on aquatic resources (which includes EFH) due to an accidental spill or leak of hazardous materials is presented in section 4.5.1.1. As noted previously, the FERC staff is currently revising its BA and EFH Assessment for the Bradwood Landing Project, which will be resubmitted to the NMFS with a request to initiate formal

consultation in compliance with section 7 of the ESA and the MSA. The FERC will respond to any EFH Conservation Recommendations issued by the NMFS through the EFH/ESA consultation process.¹³

4.5.1.3 Terrestrial Wildlife

As described in section 4.4.2, nine upland vegetative communities occur within the Zones of Concern along the waterway. These communities provide nesting, cover, dispersal, and/or foraging habitat for a variety of wildlife. Open water and wetland habitats also provide these functions for wildlife species. Potential impacts on these habitats are described and quantified in sections 4.3.2.2 and 4.4.1.1, respectively.

Wildlife species that commonly occur in the communities along the waterway are described in table 4.5.1-2. The most prevalent upland habitats within the Zones of Concern along the waterway are forest (i.e., coniferous, deciduous, mixed, early seral, and riparian forests) and wetlands (i.e., estuarine intertidal and submerged and palustrine emergent, scrub-shrub, forested, and multiple wetland types). Forest habitats provide the greatest vertical structure and support diverse faunal assemblages. Wetland habitats support diverse floral species and provide foraging and dispersal habitat for a wide variety of wildlife species. A portion of the forest and wetland habitats would also be considered riparian habitat. Similar to the other forest habitats, riparian forest provides significant vertical structure, and generally supports the most diverse faunal assemblages of the affected habitats.

General Impacts on Terrestrial Wildlife

Potential impacts from LNG carrier transit along the waterway on terrestrial wildlife species and their habitats would generally be limited to increased shoreline erosion resulting from LNG marine traffic along the Columbia River and an accidental or intentional release of LNG during transit of the LNG carriers. As discussed in detail in section 4.1.2.3, the proposed project would increase deep-draft vessel traffic by about 25 percent. The LNG carriers would be larger than most of the deep-draft ships currently using the Columbia River; although larger ships are expected to transit the Columbia River once the Columbia River Channel Improvement Project is completed. Because the blockage ratio of the LNG carriers would be greater than that of most deep-draft ships currently traveling the Columbia River, the LNG carriers could produce slightly larger waves than most of the current ships operating at the same speed. LNG carriers would travel at speeds between 8 and 12 knots while on the Columbia River. The degree to which current ship traffic affects shorelines along the waterway is difficult to quantify due to the various other factors which contribute to shoreline erosion and accretion processes. A detailed analysis of the potential for increased shoreline erosion due to LNG carrier wakes will be included in the revised BA and EFH Assessment. However, we have also recommended in section 4.1.2.3 that NorthernStar coordinate with the NMFS to determine appropriate restrictions on LNG carrier speed, or other applicable measures, to avoid or minimize shoreline erosion due to LNG carrier transit along the waterway.

¹³ Records of communications between the FERC and NMFS related to the consultation process for this project are available through <http://www.ferc.gov/docs-filing/elibrary.asp>.

TABLE 4.5.1-2

**Wildlife Species Occurring within the Vegetative Communities along the Waterway and in the Vicinity of the
Bradwood Landing LNG Terminal**

Vegetative Communities	Typical Wildlife Found within the Vegetative Communities
Forest ^a	<p>Amphibians: northwestern salamander, western red-backed salamander, roughskinned newt, western toad, Pacific treefrog, red-legged frog, bullfrog ^d.</p> <p>Reptiles: rubber boa, common garter snake, northwestern garter snake.</p> <p>Mammals: beaver, big brown bat, black bear, black-tailed deer, bobcat, bushy-tailed woodrat, California myotis, Columbian white-tailed deer, cougar, coyote, deer mouse, Douglas squirrel, elk, forest deer mouse, hoary bat, little brown myotis, long-eared myotis, long-legged myotis, mink, mountain beaver, porcupine, raccoon, red fox, Roosevelt elk, silver-haired bat, striped skunk, Townsend's chipmunk, vagrant shrew, western gray squirrel, Yuma myotis.</p> <p>Birds: American robin, bald eagle, barred owl, belted kingfisher, blue grouse, black-capped chickadee, dark-eyed junco, downy woodpecker, great blue heron, great-horned owl, hairy woodpecker, northern flicker, olive-sided flycatcher, osprey, peregrine falcon, red-breasted nuthatch, red-tailed hawk, ruby-crowned kinglet, ruffed grouse, rufous hummingbird, song sparrow, spotted towhee, Steller's jay, Swainson's thrush, varied thrush, willow flycatcher, winter wren, and yellow-rumped warbler.</p>
Scrub-Shrub ^b	<p>Amphibians: Pacific treefrog, red-legged frog, bullfrog ^d.</p> <p>Reptiles: rubber boa, northwestern garter snake, common garter snake.</p> <p>Mammals: beaver, big brown bat, black-tailed deer, California myotis, Columbian white-tailed deer, coyote, deer mouse, hoary bat, little brown myotis, long-eared myotis, long-legged myotis, mink, nutria ^d, raccoon, red fox, Townsend's vole, Yuma myotis.</p> <p>Birds: American kestrel, American robin, Bewick's wren, dark-eyed junco, great blue heron, marsh wren, song sparrow, red-winged blackbird, red-tailed hawk, rufous hummingbird, white-crowned sparrow, wood duck.</p>
Wetlands ^c	<p>Amphibians: northwestern salamander, western toad, Pacific tree frog, red-legged frog, bullfrog ^d, Oregon spotted frog.</p> <p>Reptiles: western painted turtle, northwestern pond turtle, common garter snake.</p> <p>Mammals: beaver, big brown bat, black bear, California myotis, coyote, hoary bat, little brown myotis, long-eared myotis, long-legged myotis, mink, muskrat, northern river otter, nutria ^d, raccoon, striped skunk, silver-haired bat, Townsend's big-eared bat, vagrant shrew, Yuma myotis.</p> <p>Birds: American coot, belted kingfisher, Bewick's wren, black-bellied plover, black-capped chickadee, Canada goose, cinnamon teal, cliff swallow, common snipe, dunlin, great blue heron, greater yellowlegs, mallard, marsh wren, northern harrier, northern pintail, northern shoveler, peregrine falcon, pied-billed grebe, purple finch, red-winged blackbird, short-billed dowitchers, song sparrow, sora, tree swallow, violet-green swallow, Virginia rail, western sandpiper.</p>
Streams and Ponds	<p>Amphibians: long-toed salamander, northwestern salamander, Pacific giant salamander, western toad, Pacific tree frog, red-legged frog, bullfrog ^d, Oregon spotted frog, tailed frog.</p> <p>Reptiles: western painted turtle, northwestern pond turtle, common garter snake, rubber boa.</p> <p>Mammals: beaver, big brown bat, black bear, California myotis, coyote, hoary bat, little brown myotis, long-eared myotis, mink, muskrat, nutria ^d, raccoon, silver-haired bat, Townsend's big-eared bat, Yuma myotis.</p> <p>Birds: Bewick's wren, black swift, black-capped chickadee, black-throated gray warbler, common yellowthroat, olive-sided flycatcher, peregrine falcon, rufous hummingbird, song sparrow, spotted towhee, yellow warbler, American dipper, band-tailed pigeon, barn swallow, belted kingfisher, Bullock's oriole, common merganser, great blue heron, green heron, hooded merganser, mallard, mourning dove, red-eyed vireo, ruffed grouse, spotted sandpiper, warbling vireo, willow/alder flycatcher, Wilson's warbler, wood duck, yellow-breasted chat.</p>

Dredged Materials and Bare Ground	<p>Reptiles: common garter snake, northwestern garter snake.</p> <p>Mammals: black-tailed deer, deer mouse, raccoon.</p> <p>Birds: American Crow, house sparrow ^d, killdeer, mourning dove, rock dove ^d, song sparrow, spotted towhee.</p>

^a Forested communities include coniferous, deciduous, mixed, early seral, and riparian forests.

^b Scrub-shrub communities include both upland scrub-shrub and riparian scrub-shrub.

^c Wetland communities include estuarine intertidal and submerged as well as palustrine emergent, scrub-shrub, forested, and multiple wetland types.

^d Non-native species or invasive species occurring along the waterway or at the LNG terminal site.

In the unlikely event of a collision or allision of sufficient magnitude to rupture an LNG cargo tank, it is likely that sparks or flames would ignite the flammable vapors at the spill site. If that ignition did not occur, an LNG spill would rapidly vaporize on water and form a potentially flammable cloud. If the flammable vapor cloud encountered an ignition source, the cloud would burn back to the spill site, rather than outward towards shoreline habitats. However, it is possible that ignition of the LNG vapors could contribute to a forest fire in areas where the Columbia River navigation channel is adjacent to forested areas (e.g., between Altoona and Skamokawa). Given the relatively high precipitation in the region, large forest fires in the area are infrequent but they can be severe when they do occur. The intensity and extent of a potential forest fire would be highly dependent on a number of variables including available fuel (e.g., woody material), moisture and temperature, fuel composition, wind, and topography. With implementation of the mitigation measures described in the Coast Guard's WSR (Appendix G), an LNG release would be highly unlikely, and therefore, the potential impacts on terrestrial wildlife would be less than significant.

Unique or Sensitive Wildlife Habitats

Julia Butler Hansen National Wildlife Refuge

The JBHNR is located between CRMs 33.5 and 39 and includes the Hunting Islands and Price Island in Washington as well as Tenasillahe Island, portions of Crims Island, Wallace Island, and several mainland parcels in Oregon. It contains approximately 6,100 acres of pasture, forested tidal swamp, brushy woodlots, marshes and sloughs along the Columbia River, including nearly 4,800 acres of diked floodplain and undiked islands. As described in section 4.6.1.1, the JBHNR supports three subpopulations of Columbian white-tailed deer, which are federally listed as endangered under the ESA. During transit along the waterway, LNG carriers within the navigation channel would be adjacent to JBHNR refuge lands between CRM 33.5 and the proposed LNG terminal. Although potential impacts on the JBHNR resulting from LNG marine traffic associated with the proposed project would be limited to increased shoreline erosion and an accidental or intentional release of LNG during transit of the LNG carriers, these impacts could negatively influence management and recovery activities within the JBHNR as discussed below.

As discussed above and in section 4.1.2.3, the proposed project would increase deep-draft vessel traffic by about 25 percent. The degree to which current ship traffic affects shorelines along the waterway is difficult to quantify due to the various other factors which contribute to shoreline erosion and accretion processes. Therefore, it is difficult to determine what additional impacts on the shorelines of the JBHNR would occur as a result of increased LNG marine traffic. However, we have recommended in section 4.1.2.3 that NorthernStar coordinate with the NMFS to determine appropriate restrictions on LNG carrier speed, or other applicable measures, to avoid or minimize shoreline erosion due to LNG carrier transit along the waterway. In addition, NorthernStar prepared a *Shoreline Monitoring Plan*, which is described in section 4.1.3.3 that includes measures to reduce erosion of downstream banks should such erosion increase as a result of the project. The FERC staff continues to study this issue and additional analysis regarding shoreline erosion will be included in the revised BA and EFH Assessment.

Potential impacts on the JBHNR from a release of LNG and associated fire include habitat modification as well as injury or mortality of species occurring within the JBHNR. In its December 21, 2007 letter on the draft EIS, the U.S. Department of the Interior stated that Tenasillahe Island and the Mainland Refuge Unit would be especially vulnerable to adverse effects associated with the release of LNG and associated fire. In the event of a collision or allision of sufficient magnitude to rupture an LNG cargo tank, it is likely that sparks or flames would ignite the flammable vapors at the spill site. In the unlikely event that ignition did not occur, an LNG spill would rapidly vaporize on water and form a potentially flammable vapor cloud. If the flammable vapor cloud encountered an ignition source, the

LNG vapors could contribute to a forest fire within the JBHNR. Given the relatively high precipitation in the region, large forest fires in the area are infrequent but they can be severe when they do occur. The intensity and extent of a potential forest fire and the resulting damage to the JBHNR would be highly dependent on a number of variables including the extent of the LNG spill, available fuel (e.g., woody material), moisture and temperature, fuel composition, wind, and topography. Approximately 5,000 acres of the JBHNR are within the Zones of Concern, a portion of which could be affected if an accidental or intentional breach of an LNG carrier were to occur during transit. However, as discussed in section 4.11.5.3, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G). Potential impacts on the Columbian white-tailed deer as a result of an LNG release are discussed in section 4.6.1.4.

Lewis and Clark National Wildlife Refuge

The LCNWR is located between CRMs 18.5 and 35 and includes 35,000 acres of islands, bars, mud flats, and tidal marshes in the Columbia River estuary. The eastern boundary of the refuge is located immediately west of the JBHNR on Welch Island. The refuge is the largest marsh in western Oregon and was established to preserve wetland habitats in the lower Columbia River estuary and serve as a wintering area for migratory waterfowl and shorebirds. The LCNWR provides resting habitat for peak populations of 1,000 tundra swans, 5,000 Canada geese, and 50,000 ducks in February and March before the northward migration. Between 30 and 35 active bald eagle nests occur within the refuge. In addition, estuarine waters within the refuge provide foraging habitat for juvenile salmonids before entering the Pacific Ocean. Other fish species using the estuary include shad, smelt, perch, starry flounder, bass, catfish, and Pacific lamprey. Pacific harbor seals use sandbars and mud flats as resting sites at low tides, while seals and California sea lions feed on fish in the estuary. Beaver, raccoon, weasel, mink, muskrat, and river otter also live on the islands. Potential impacts on the LCNWR resulting from LNG marine traffic associated with the proposed project would be limited to increased shoreline erosion and an accidental or intentional release of LNG during transit of the LNG carriers. The potential for increased shoreline erosion at the LCNWR would be similar to that described above for the JBHNR.

The islands composing the LCNWR occupy approximately 21,800 acres within the Zones of Concern, a portion of which could be affected if an accidental or intentional breach of an LNG carrier were to occur during transit. Potential impacts on the LCNWR from a release of LNG and associated fire would be similar to those described above for the JBHNR and include habitat modification as well as injury or mortality of species occurring within the LCNWR. The intensity and extent of a potential forest fire and the resulting damage to the LCNWR would be highly dependent on a number of variables including the extent of the LNG spill, available fuel (e.g., woody material), moisture and temperature, fuel composition, wind, and topography. Similarly, injury and mortality to species would also be dependent on the time of year that the incident occurred as well as the mobility of the species.

Fort Stevens State Park

Fort Stevens State Park comprises approximately 4,300 acres and is located west of Warrenton, Oregon. According to the *Oregon Estuary Plan Book* (ODLCD, 2007), this state park contains some significant wildlife habitat. Two islands north of Fort Stevens State Park within the Columbia River also contain significant habitat. Potential impacts on Fort Stevens State Park resulting from the proposed project would be similar to those described above for the JBHNR and LCNWR.

Mitigation Measures

As part of its Compensatory Mitigation Plan, NorthernStar would restore areas along the shoreline of the lower Columbia River at Svensen Island and preserve habitat at the mouth of Hunt Creek. However, the existing version of the Compensatory Mitigation Plan does not include a discussion of potential impacts on habitat due to LNG carrier traffic. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. To ensure that the proposed mitigation adequately compensates for project-related impacts, including impacts on downstream habitats from shoreline erosion, we recommended that NorthernStar continue to consult with the appropriate natural resource agencies to finalize its Compensatory Mitigation Plan. The final Compensatory Mitigation Plan would be filed along with agency comments and applicable approvals with the Secretary prior to construction of the project.

4.5.2 LNG Terminal

4.5.2.1 Aquatic Resources

The Bradwood Landing LNG terminal, which would be located at CRM 38, is upstream of the extent of saltwater intrusion (near Grassy Island at CRM 30) and is near the upriver estuarine boundary at CRM 38 (downstream edge of Puget Island) (Fox et al., 1984). The Columbia River near the LNG terminal site provides habitat for a variety of anadromous and resident fish species and is discussed below. A detailed discussion of aquatic species that have designated EFH in the vicinity of the LNG terminal or are listed as endangered or threatened is included in sections 4.5.2.2 and 4.6.1.1, respectively.

Existing Aquatic Resources

Marine Fish

Because the LNG terminal would be located near the upriver estuarine boundary of the Columbia River, with the exception of the starry flounder, marine species are not likely to occur at the proposed site. The starry flounder has been known to swim greater than 75 miles up major rivers but does not follow any migratory trend (NMFS, 2006e). All life stages (eggs, larvae, juveniles, and adults) of the starry flounder are present in estuaries; however, only juveniles and adults occur in freshwater. The starry flounder is discussed in detail in section 4.5.2.2.

The Columbia River near the LNG terminal site provides habitat for both anadromous and resident fish species. These species are described under the waterway for LNG marine traffic in section 4.5.1.1.

Freshwater Fish

Resident freshwater fish within the project area include both coldwater (trout) and warmwater (bass, crappie, and bluegill) species. These species are described in section 4.5.1.1.

Marine Mammals

Steller sea lions, California sea lions, and Pacific harbor seals use haulout sites along the lower Columbia River and may occur in the vicinity of the proposed LNG terminal (Appendix C). These species and other marine mammals are protected by the Marine Mammal Protection Act of 1972 and are described further in section 4.6.1.3. In addition to protection under the Marine Mammal Protection Act, Steller sea lions are federally and state-listed and are described in section 4.6.1.1.

Commercial and Recreational Fisheries

Commercial and recreational fisheries of the lower Columbia River are described in section 4.5.1.1.

Fisheries of Special Concern

Fisheries resources of special concern occurring in the vicinity of the LNG terminal include: 1) federally designated EFH for coho and Chinook salmon, as well as starry flounder; 2) species listed federally as threatened, endangered, or candidates for listing under the ESA and their designated or proposed critical habitat; and 3) species listed as threatened or endangered by the State of Oregon. Potential impacts on EFH at the LNG terminal are discussed in section 4.5.2.2. Potential impacts on federally and state-listed species and their critical habitat are discussed in section 4.6.2.2.

Impacts on Aquatic Resources

General project activities associated with the proposed LNG terminal that could potentially impact aquatic resources include in-water construction activities, habitat modification, water appropriations, artificial lighting, accidental spills or leaks of hazardous materials, and operation of the LNG terminal. Much of the impact discussion included below applies to fish protected under the ESA, which are described in detail in sections 4.6.1.1 and 4.6.2.2, and to EFH designated under the MSA, which is discussed further in section 4.5.2.2. As described above, Steller sea lions occurring within the vicinity of the proposed LNG terminal are protected under the ESA and the Marine Mammal Protection Act and are discussed in detail in sections 4.6.1.1 and 4.6.2.2.

In-Water Construction Activities

Fish, marine mammals, and other aquatic resources could be impacted by in-water construction activities including dredging, development of the river shoreline, pile driving, and filling of the log pond at the LNG terminal site. Direct impacts of in-water construction activities on aquatic resources would include the displacement of aquatic resources within the affected area and direct mortality of some individuals. During construction activities, mobile species, such as fish and marine mammals, would be expected to leave the vicinity of the project area. Animals displaced by construction activities may relocate into similar habitats nearby; however, the lack of adequate territorial space could force some animals into suboptimal habitats. The influx and increased density of animals in some undisturbed areas caused by these dislocations could increase inter- and intra-species competition and also reduce the reproductive success of animals that are not displaced by construction. The loss of these individuals could result in a decrease in the food stock available for predators of these species.

Comments were received on the draft EIS regarding impacts on shallow water habitat due to construction of the LNG terminal facilities. As described in section 4.4.1.1, shallow water habitat is defined as being between elevations slightly above MLLW and 6 feet below MLLW. Medium depth water is between 6 and 18 feet below MLLW, while deep water is defined as 18 feet and deeper (LCFRB, 2004). However, shallow water habitat as it relates to fish habitat generally refers to waters less than 20 feet deep. Therefore, the discussion of shallow water habitat that follows includes the shallow and medium depth water as defined by the LCFRB. Based on the description of the maneuvering area and berth in section 2.1.3, in-water construction activities impacting shallow water habitat would be limited to the driving of piles associated with the berth, which would occupy less than 0.1 acre of habitat. It is important to note that the ship berth and maneuvering area would be located approximately 300 feet from the shore. Therefore, direct impacts on shallow water habitat as a result of dredging are not anticipated.

The degree of impacts on aquatic resources associated with construction activities would depend on the timing of in-water construction. Construction during periods of sensitive fish activity (i.e., spawning, juvenile rearing, and migration) can have a greater impact on fish than construction during other periods. To minimize impacts on fish in the Columbia River, NorthernStar would limit dredging and other in-water activities to the November 1 through February 28 in-water work window recommended by the NMFS (NMFS, 2005a). Similarly, in-water activities at Hunt Creek would be limited to the July 1 through September 15 in-water work window recommended by the ODFW (ODFW, 2000).

Dredging

The water column and substrate in the vicinity of the proposed LNG terminal provides habitat for spawning, breeding, feeding, growth, migration, and shelter to numerous species of fish. Additionally, prey species occur within the water column and sediments within the ship berth and maneuvering area.

As discussed in section 2.4.1.2, NorthernStar proposes to dredge the LNG carrier berth and maneuvering area using a hydraulic cutterhead dredge with a 30-inch discharge pipe and a 4,950 horsepower pump. Dredging equipment would operate 24 hours per day, 7 days per week, pending any restrictions specified in the permits necessary for these activities. The exact time needed for dredging would depend on a number of variables that cannot be predicted, such as weather and river conditions; however, NorthernStar estimates that the dredging would be accomplished in about 48 to 72 days. Construction of the berth would require the removal of 700,000 cubic yards of sediments, increasing the water depth from an average of -33 feet CRD to -42 feet CRD with a 1-foot overdredge allowance. Dredging activities have the potential to impact aquatic resources through habitat alteration, temporary increases in suspended sediment and turbidity levels, removal of benthic organisms, resuspension of contaminated sediments, entrainment, increased noise, and alterations to sediment transport and deposition.

Habitat Alteration. Dredging of the berth and maneuvering area would result in permanent modification of aquatic habitats. Removing sediment from the river bottom, increasing the water depth an average of approximately 9 feet, and constructing over-water structures could potentially affect use of the project area by aquatic species. The removal of sediment from the river bottom is discussed in section 4.2.2.2. Increasing the water depth an average of approximately 9 feet could potentially result in reduced use of the area by juvenile fish. However, NorthernStar would mitigate for reduced habitat quality at the berth and maneuvering area through restoration and/or preservation of several times as much area of high quality habitat at the Svensen Island and Hunt Creek Mitigation Sites (see *Mitigation Measures*, below). Impacts on aquatic species from construction of over-water structures is discussed below (see *Habitat Modification, Over-water Structures*).

Increased Suspended Sediment and Turbidity Levels. Both anadromous and resident fish populations could be impacted by increased concentrations of suspended sediments as a result of dredging activities. This increase, known as a sediment plume, may delay or divert migratory passage and, in some instances, could cause total avoidance of an area by fish. Increased sedimentation can also adversely affect fish eggs and juvenile fish survival, benthic community diversity and health, foraging success, and suitability of spawning habitat. Suspended particles and sediment can result in increased turbidity, reducing in-water visibility that can affect the ability of sight-feeders to locate prey. In sufficient quantities, increased turbidity levels can affect oxygen exchange over the gills in aquatic species, resulting in weakened individuals or mortality. Additionally, sediments in the water column can be redeposited on downstream substrates, which could bury aquatic macroinvertebrates (an important food source for many species of fish). These potential effects could be exacerbated if the fish are in generally poor condition and under stress by other factors (i.e., increased water temperature).

The size and duration of the sediment plume is highly dependent upon the grain size of the material being dredged. As described in section 4.2.2.2, SWCA conducted a sediment analysis of the material which would be dredged as part of the proposed project. Within the dredge footprint, the substrate is almost exclusively sand, with very low silt and clay components (SWCA, 2006). Sand settles rapidly in the water column. In addition, WEST (2006) conducted hydraulic and sediment transport analyses using a combination of the RMA2 hydrodynamic model and the SED2D-WES sediment transport model (WEST, 2006). Based on its modeling, WEST concluded that the maximum sediment concentration would occur within 10 feet of the cutterhead. WEST's hydrodynamic modeling predicts project-related suspended sediment loads would be a maximum of 1 mg/L at the dredge site and diminish to 0.1mg/L before reaching Tenasillahe Island. By comparison, background measurements of TSS during the field program were on the order of 10 mg/L. Therefore, even assuming a considerable level of uncertainty in any of the model parameters, the impacts of the dredging operation would be very small and confined to an area immediately surrounding the proposed facility. The combined background and project-related suspended sediment concentrations are well below the lethal level for fish (WEST, 2006; Newcombe and MacDonald, 1991).

Background levels of turbidity in the Columbia River range from 3 to 8 NTUs. As discussed in section 4.3.2.3, WEST concluded that turbidity plumes from cutterhead dredging similar to the proposed dredging at Bradwood would return to within 1 NTU of background levels within 1 minute after suspension (WEST, 2006). Servizi and Martens (1992) found that 37 NTUs is the threshold for avoidance by juvenile coho and steelhead. Although the WEST report does not provide the maximum turbidity levels expected during dredging activities, the predicted suspended solid concentrations provided above indicate that turbidity levels from dredging activities would be well below the 37 NTU threshold. Therefore, impacts on aquatic species from increased turbidity levels would not be significant.

Removal of Benthic Organisms. Dredging may adversely affect prey species at the LNG terminal site by directly removing or burying immobile invertebrates. Species of aquatic organisms that exist on or within the bottom sediments include the sand shrimp (*Crangon* spp.), daphnia (*Daphnia* spp.), and copepods. These are all important prey organisms for the fish species present in the estuary (Bottom and Jones, 1990). Recolonization varies considerably with geographic location, sediment composition and types of organisms inhabiting the area (Kennish, 1997). Rates of recovery range from several months to as much as 2 to 3 years based on substrate type and currents in the affected area (NMFS, 2003).

Resuspension of Contaminated Sediments. SWCA (2006; 2007) conducted sediment sampling and analysis to determine the presence of contaminants within the proposed dredged materials and leave surface. As discussed in section 4.2.2.2, no elevated contaminant concentrations were detected. Comments were received on the draft EIS related to the potential for bioaccumulation of contaminants to occur due to dredging activities. The long-term bioaccumulative effects of pollutants on aquatic resources resulting from construction and operation of the proposed project cannot be characterized with the best available science. Bioaccumulative effects can result from a variety of physical, chemical, and biological processes. However, the concentration of contaminant levels reported in section 4.2.2.2 of the EIS does not indicate a likely significant biological effect.

Entrainment. Some fish may be susceptible to entrainment during dredging operations. Entrainment occurs when small fish (such as juvenile salmonids), eggs, and larvae are drawn through the screens of water intakes and cannot escape. Adult fish of medium to large species (such as salmonids) have sufficient swimming ability to avoid entrainment by dredging if they are present in the vicinity of dredges. NorthernStar would minimize fish entrainment during dredging activities by keeping the cutterhead within 3 feet of the river bottom and conducting dredging activities during specified in-water work window when the densities of fish in the project area is lowest.

Increased Noise. Dredging activities associated with construction and operation of the project would generate underwater sound pressure levels that could elicit responses in some fish, marine mammals, and other aquatic organisms (Richardson et al., 1995). Unfortunately, relatively little is known about the effects from exposure to underwater sound on most aquatic organisms, particularly fish (Hastings and Popper, 2005). Even in cases where data are available, most experts recommend extreme caution in attempting to extrapolate between species (Hastings and Popper, 2005). The intensity of the sound pressure levels from dredging activities can be quite variable. However, sound pressure levels are generally in the range of 112 to 160 decibels (dB) (re: 1 microPascal (μ Pa)), intensities that may influence organism behaviors or perceptions, but are unlikely to cause physiological damage (Richardson et al., 1995; Hanson et al., 2003). As described in section 4.6.2.2, it is possible that marine mammals could be adversely impacted by dredging activities. NorthernStar proposes to implement protective measures including the establishment of Safety, Buffer, and Impact Zones to protect the Steller sea lion during construction activities at the LNG terminal. To provide similar protections to other pinnipeds potentially occurring in the project area, we have recommended that NorthernStar expand the protective measures that would be used to avoid or minimize impacts on Steller sea lions during construction of the LNG terminal (i.e., Safety, Buffer, and Impact Zones) to include all pinnipeds (see section 4.6.2.2).

Alterations to Sediment Transport and Deposition. In addition to impacts on aquatic resources during dredging activities, dredging the berth and maneuvering area would result in long-term impacts on sediment transport and deposition. As discussed in section 4.2.2.2, modeling conducted by WEST analyzed potential impacts on sediment transport and deposition at low flow (125,000 cfs), normal flow (210,000 cfs), high flow (545,000 cfs), and extremely high flow conditions (864,000 cfs). Based on the WEST model, the proposed project would cause a reduction in stream flow through the Clifton Channel, resulting in a reduction of the water surface profile, shear stresses, and flow velocities through the channel. As a result of this, deposition may occur during high flows along the Clifton Channel. However, the results do not show significant changes to the overall bed conditions in the Clifton Channel for the range of flows modeled. Although the results of the WEST model did not indicate that significant changes to Clifton Channel would be anticipated, the small changes in the hydraulic characteristics associated with the proposed project could result in changes to existing fish habitats within other portions of the lower Columbia River.

As described in section 4.2.2.2, numerous comments were received on the draft EIS regarding the adequacy of the WEST modeling. As it relates to potential impacts on aquatic resources, the model does not address long-term alterations to sediment transport and deposition within Clifton Channel and/or the lower Columbia River, which could alter biological function and value for aquatic resources. Impacts on aquatic resources (including salmonids) attributed to changes in sediment transport and deposition may occur as a result of the proposed project. Additional analysis of potential impacts on salmonids from alterations to sediment transport and deposition will be included in the revised BA and EFH Assessment.

The biological impacts on aquatic resources from these changes would depend upon their location. For the fish in the Clifton Channel, there would be little impact. Fish in the main channel during flood flows would be affected by the increased size of the sediment plume from Puget Island. However, during high flows it is unlikely that fish would be present within the main channel. Salmonids and other fish tend to seek sheltered, off-channel locations during high flows. Although detailed data on fish distribution in the area during flood events is not available, the literature supports the idea that fish would avoid the main channel during periods of high flow in favor of Clifton Channel.

Development of the River Shoreline

Development of the river shoreline and has the potential to cause siltation at the water's edge and temporarily increase suspended sediment and turbidity levels in the water column that would affect

downstream habitat, fish health, and feeding behavior in the affected area (see *Dredging*). NorthernStar would implement BMPs from its terminal ESC Plan during construction of the LNG terminal, which would minimize impacts on aquatic resources by controlling erosion along the shoreline and lessen sediment movement.

Pile Driving

Tubular steel piles would be installed as part of the construction of the marine terminal (i.e., for breasting/mooring dolphins and unloading platforms/trestles) over a period of approximately 4 months. The actual number of days when pile driving would occur during this 4-month period depends on a number of variables such as weather and river conditions; however, NorthernStar estimates that about 60 days of pile driving would be required. Those days could be spread throughout the 4-month period. Studies have shown that the sound waves from pile driving may be intense enough to result in injury or trauma to fish, sea turtles, and other animals with gas-filled cavities, such as swim bladders, lungs, sinuses, and hearing structures (Hastings and Popper, 2005; Abbott and Bing-Sawyer, 2002).

Although the effects of pile driving are poorly studied and there appears to be substantial variation in a species' response to sound, intense sound pressure waves can change fish behavior or injure/kill fish through rupturing swim bladders or causing internal hemorrhaging (Hastings and Popper, 2005). The degree to which an individual fish exposed to sound waves would be affected is dependent upon variables such as the peak sound pressure level and frequency as well as the species, size, and condition of a fish (e.g., small fish appear to be more susceptible to injury by intense sound waves than are larger fish of the same species). The presence of predators can also influence how a fish might be affected by pile driving (e.g., fish stunned by pile-driving activities may be more susceptible to predators). In any case, forms of impact on marine organisms that could result from underwater sound levels include:

- Behavioral – interruption of normal behaviors (e.g., feeding, breeding, and/or nursing) and displacement;
- Perceptual – masking biologically important sounds (e.g., communication, predator/prey recognition); and
- Physiological – damage to body tissue.

In discussing the impacts of sound on aquatic resources it is important to note the difference in sound intensity in air versus water. Sound intensity in air uses a standard of 20 microPascals (μPa), while sound intensity measured in water uses a standard level of 1 μPa . There is a difference of 26 dB when converting air to water sound pressure levels. Therefore, if pile driving emits 201 dB in air, the underwater sound would be 227 dB re: 1 μPa . The NMFS' current noise thresholds for fish are a peak pressure of 180 dB re: 1 μPa for physical harm and an impulse pressure, or root mean square (rms), of 150 dB_{rms} re: 1 μPa for behavioral disruption (NMFS, 2007a).

The intensity of the sound pressure levels produced during pile driving depends on a variety of factors including, but not limited to, the type and size of the pile, the firmness of the substrate into which the pile is being driven, the depth of water, and the type and size of the pile-driving hammer. Driving hollow steel piles with impact hammers can produce sharp spikes of sound that are intense enough to injure fish. For example, driving 96-inch-diameter steel piles using an impact hammer has been shown to generate peak sound pressure levels of up to 227 dB re: 1 μPa at 16 feet (Hastings and Popper, 2005). Close to piles, the impulse pressure is typically about 10 to 15 dB lower than the peak pressure. This level, however, is dependent not only on the pile and hammer characteristics, but also on the geometry

and boundaries of the surrounding underwater environment (Hastings and Popper, 2005). In some cases, fish may be startled by the first few strikes of an impact hammer. However, this response can wane and the fish may remain in the area (NMFS, 2001). As such, the potential effect on fish from impact hammers could be magnified because fish would not only be exposed to intense sound waves but may not avoid pile-driving activities, which would prolong their exposure to the potentially harmful sounds and increase their risk of injury or death. In a review of studies documenting fish kills associated with pile driving, the NMFS reported that all have occurred during use of an impact hammer on hollow steel piles (Hanson et al., 2003). On the other hand, the rapid repetitions of vibratory hammers produce relatively low intensity sound waves. Evidence also suggests that fish consistently display an avoidance response to sound from a vibratory hammer, even after repeated exposure (Dolat, 1997; Knudsen et al., 1997).

In addition to fish, Steller sea lions, California sea lions, and Pacific harbor seals may occur in the vicinity of the LNG terminal. Steller sea lions are described in detail in section 4.6.1.1. California sea lions occur along the lower Columbia River during the winter and spring using navigation buoys, jetties, and log booms (Jeffries et al., 2000). In addition, Pacific harbor seals occupy haulout sites on intertidal mudflats and sand bars along the northeast side of Welsh Island and the east end of Puget Island (Jeffries et al., 2000). In the event that a Steller sea lion or other marine mammal happens to be transiting the area during pile driving activities, it would be expected to avoid the immediate area in response to a higher level of human activity and noise associated with construction.

To minimize impacts on aquatic species as a result of pile driving, NorthernStar proposes to implement the following measures:

- observe in-water work windows – NorthernStar indicated that pile driving would only occur during the in-water work window established by the ODFW and the NMFS (November 1 through February 28) in order to minimize the number of fish exposed to high underwater noise levels.
- install 48-inch, 54-inch, 84-inch, and 96-inch diameter steel piles – NorthernStar proposes to install larger than normal steel pilings to minimize the number of piles and allow all piles to be installed vertically so that each pile can be driven with a caisson filled with bubbles to do the maximum possible to minimize acoustic impacts on aquatic resources (see reduction of peak sound pressure levels). Additional details regarding the number, length, and size of the piles as well as water depth is provided in table 2.1.3-1.
- utilize vibratory pile driving as conditions allow – NorthernStar would use vibratory pile driving equipment to install piles for the LNG carrier dock and mooring dolphins to the maximum extent possible before impact hammers would be used. Vibratory drivers tend to produce lower noise and vibration levels for most applications than impact pile drivers.
- reduction of peak sound pressure levels – NorthernStar would use two alternative measures to reduce peak in-water sound pressure levels:
 - Air bubble curtains have been used in a variety of pile driving applications to reduce underwater noise levels. NorthernStar would use a bubble curtain system that is contained within a caisson surrounding the driven piling. An attempt would be made to remove the water between the caisson and the pile to maximize the noise attenuation. If the water could not be removed, performance standards would be established which would specify a rate and distribution of bubbles. Prior to pile driving, the bubbler apparatus would be tested in similar water depths without the caisson to allow visual inspection of the bubble distribution by

divers and video cameras. If the bubbles are not uniform from bottom to surface, additional distribution rings may be added. For each pile installation, the bubble curtain would be activated before the initial vibratory pile driver stage to verify the performance of the bubble curtain. When properly deployed and operated, unconstrained bubble curtains can provide from 15 to 30+ dB of sound level reduction, even in currents on the order of 2 miles per hour (Hardyniec and Skeen, 2005; Jones, 2003). A noise reduction value of 25 dB for air bubble curtains is estimated.

- NorthernStar would also use a pile cap between the hammer and the pile during impact pile driving to further reduce underwater noise levels if monitoring indicates the bubble cushion within the caisson is not achieving the desired sound pressure reduction. The potential noise reduction provided by pile caps is not well documented in technical literature. However, Laughlin (2006) measured sound levels resulting from driving a 12-inch-diameter standard steel pile using bubble curtains and different pile cap materials. The results of the study indicated that using wood as a pile cap may provide a noise reduction value of 11 to 26 dB; however, wood compressed easily or caught on fire and therefore does not warrant regular use. Conbest™ (a canvas based laminate used in conjunction with a special Aluminum alloy) provided a noise reduction value of 7 to 8 dB, nylon provided a noise reduction value of 4 to 5 dB, and Micarta provided a noise reduction value of 1 to 5 dB.

The NMFS has raised concerns regarding the use of wood blocks during impact pile driving because of the potential for fire when used on large piles. Based on these concerns, NorthernStar has agreed to either eliminate the use of wood blocks, use wood blocks only during pile proofing, or to use a different material for a pile cap.

With the implementation of the above measures (25 dB of noise reduction from the caisson/air curtain and 5 dB of noise reduction from the cap) underwater sound pressure levels would not exceed 190 dB re: 1 µPa farther than about 33 feet from the pile and would not exceed 155 dB re: 1 µPa farther than approximately 7,053 feet from the pile when using the following equation:

$$L_r = L_s - 15 \log (D_1/D_2)$$

Where: L_r is received noise level in dB re: 1 µPa;
 L_s is the noise source at a specified distance;
 D_1 is the radial distance; and
 D_2 is the source level distance.

This formula generally provides for a spreading loss of 4.5 dB per doubling of distance. Cylindrical spreading occurs when sound energy spreads outward in a cylindrical fashion bounded by the bottom sediment and water surface (i.e., shallow water), resulting in a spreading loss of 3 dB per doubling distance. Spherical spreading occurs when the when the source encounters little to no refraction or reflection from boundaries (i.e., deep water), resulting in a 6 dB reduction per doubling of distance. Because all pile driving would occur in a depth of 40 feet or less, the practical spreading loss of 4.5 dB per doubling of distance is appropriate.

As previously discussed, in-water monitoring would be completed to document that the appropriate noise attenuation procedures are being used to attenuate the pile driving noise and minimize

the distance to the NMFS' current noise thresholds for fish of 180 dB re: 1 μ Pa peak pressure for physical harm and 150 dB_{rms} re: 1 μ Pa impulse pressure for behavioral disruption (NMFS, 2007a).

The NMFS raised concerns in its May 11, 2007 letter to the FERC regarding the method of noise monitoring proposed by NorthernStar and the efficacy of bubble curtains during pile driving activities. NorthernStar proposes to use a qualified underwater acoustic monitor to record sound pressure levels once pile driving has begun. As described above, bubble curtains would be used to attenuate noise from pile driving activities and minimize potential impacts on aquatic resources. If bubble curtains did not function properly or were found to be ineffective, adverse impacts on sensitive aquatic resources could occur. Thus, **we recommend that:**

- **NorthernStar should consult with the appropriate federal and state agencies to develop a revised Bubble Curtain Contingency Plan that establishes a performance standard to assess whether or not bubble curtains are adequately working. The plan should describe specific noise attenuation methods to be implemented if monitoring indicates poor noise attenuation performance. The plan, including agency comments on the plan, should be filed with the Secretary for the review and written approval of the Director of OEP prior to beginning offshore pile driving activities at the LNG terminal.**

As described in section 4.6.2.2, it is possible that marine mammals could be adversely impacted by pile driving. NorthernStar proposes to implement protective measures including the establishment of Safety, Buffer, and Impact Zones to protect the Steller sea lion during construction activities at the LNG terminal. To provide similar protections to other pinnipeds potentially occurring in the project area, we have recommended that NorthernStar expand the protective measures that would be used to avoid or minimize impacts on Steller sea lions during construction of the LNG terminal (e.g., Safety, Buffer, and Impact Zones) to include all pinnipeds (see section 4.6.2.2).

Log Pond Filling

Filling the log pond at the LNG terminal site would result in a permanent loss of suitable off-channel refugia and rearing habitat that is used by various species of fish. The log pond potentially provides at least seasonal refugia during high flow for both rearing salmonids as well as resident and anadromous estuarine species. The primary salmonids expected to occur in the log pond include Chinook and coho salmon; however, the pond serves as designated critical habitat for 12 federally listed endangered or threatened salmonid ESU/DPSs. Based on constraints of site construction, filling the log pond is unavoidable. The pond would be filled entirely by material dredged from the ship berth and maneuvering area. As discussed in the *Fish Salvage Plan*, before and during filling of the log pond, NorthernStar would capture and remove fish using a trap, seine, electrofishing, or other methods to minimize risk of injury to fish. As soon as possible after having been identified, counted by age class to the extent practicable, and recorded, fish would be released into a safe release site within Hunt Creek just downstream of the entrance to the log pond outlet. To minimize re-entry of individuals into the log pond during collection efforts, **we recommend that:**

- **During fish collection efforts at the former mill log pond at the LNG terminal, NorthernStar should place nets at the outlet of the log pond that only allow emigration from the pond (e.g., winged fyke net without collection chamber attached or two disconnected block nets oriented outward from the pond).**

All fish capture work would be performed or supervised by qualified fisheries biologists and would operate under the NMFS's and ODFW's fish salvage guidelines. In addition, all work would be

performed under an ODFW/NMFS scientific collection permit and resource agency personnel would be invited to participate in or oversee the operations. Although all fish capture work would occur during the recommended in-water work window for the Columbia River, direct handling may adversely impact individual fish. NorthernStar would mitigate for impacts on fish and the permanent loss of habitat from filling the log pond by developing high quality replacement habitat in consultation with the NMFS and ODFW.

Habitat Modification

Fish, marine mammals, and other aquatic resources could be impacted indirectly by activities that alter terrestrial and riparian habitat including construction of the LNG terminal, the Hunt Creek Bridge replacement, realignment of the railroad tracks, and construction of the power line. In addition, during operation of the LNG terminal, over-water structures would result in habitat modification for aquatic resources. A discussion of potential impacts on aquatic resources as a result of these activities is provided below.

LNG Terminal

Fish and other aquatic resources could be impacted indirectly by activities that alter terrestrial and riparian habitats at the LNG terminal site during construction. The clearing of vegetation and grading activities during construction could increase water temperatures as well as erosion and suspended sediment levels in the Columbia River and Hunt Creek.

Vegetative clearing at the LNG terminal would remove about 14.8 acres of wetlands and 43.5 acres of upland scrub-shrub and forested habitats, which would expose the land to increased sunlight and result in indirect increases in water temperatures as water flows over the warmer land surface and eventually reaches the Columbia River or Hunt Creek (Beschta and Taylor, 1988). As described in section 4.3.2.1, the Columbia River is currently out of compliance for water temperature (ODEQ, 2007; WDE, 2006b). The effects of water temperature on the life stages of salmonids have been extensively reviewed by McCullough (1999). Maximum water temperatures ranging from 71.6 °F to 75.2 °F limit the distribution of many salmonids. For example, the optimum temperature for growth for the spring Chinook salmon is 60.1 °F; higher temperatures during summer could reduce growth and lead to increased mortality rates (McCullough, 1999). In some cases, higher temperatures and increased light can lead to increased production of in-stream microorganisms, algae, fungi, and macroinvertebrates, thereby boosting food availability for salmonids and in turn increasing salmonid production. Warmer stream temperatures may also accelerate fry emergence and extend the growing season, thereby enhancing fish growth. However, these potential positive effects generally occur in the summer and are often offset by fish losses because of reduced protective cover from LWD (Murphy et al., 1986; Hicks et al., 1991). Elevated water temperatures may also favor production of fish species that can out-compete salmonids in some situations (Bisson et al., 1992).

Alteration of the natural drainage ways or compaction of soils by heavy equipment near streambanks during construction may accelerate erosion of the banks, runoff, and the transportation of sediments into waterbodies. NorthernStar would minimize potential impacts on waterbodies during construction by implementing the procedures in its pipeline ESC Plan for Oregon and SWPPP for Washington. To avoid impacts on water quality during operation of the LNG terminal, riparian areas outside of the berm would be allowed to permanently revegetate. As described in section 4.4.2.2, a riparian buffer at least 30 feet wide, as measured from the MHW mark, would be allowed to permanently revegetate adjacent to Hunt Creek. NorthernStar would replace cleared trees at a 5:1 ratio within the LNG terminal site, resulting in about 1,895 trees being planted following construction. The majority of the replacement trees (e.g., cottonwood, Sitka spruce, red alder, Pacific willow, and other native species) would be installed within a 100-foot buffer along the northern edge of the proposed construction

boundary. This area would serve as a forested buffer from the terminal site to the adjacent Hunt Creek estuary. NorthernStar has developed a monitoring plan and performance standards to measure successful revegetation of the site. If necessary, NorthernStar would take steps to control and remove noxious and invasive species in accordance with our Procedures. Noxious weeds and other invasive plant species are discussed in detail in section 4.4.2.3.

Power Line Construction

Construction of the power line could potentially impact aquatic resources in the vicinity of the LNG terminal. The nine streams crossed by the 1.5-mile-long power line are relatively narrow and steep, and are not believed to provide habitat for fish. The clearing and grading of vegetation during construction could increase erosion along streambanks and turbidity levels in the waterbodies. Because the downstream distances between the waterbodies crossed by the power line and Hunt Creek are over 0.5 mile, impacts on fish would not be anticipated. The overland distance between these waterbodies and the Columbia River ranges between 0.1 mile and 0.3 mile; however, the relief of the area is such that sediment movement into the Columbia River would not be anticipated. The power line would be owned and operated by PacifiCorp. Proposed measures to avoid impacts on aquatic resources would include revegetation, implementation of BMPs, and other measures specified in permits obtained by PacifiCorp.

Access Roads and Hunt Creek Bridge Replacement

The modifications to access roads and the replacement of Hunt Creek Bridge could potentially impact salmonids in lower Hunt Creek through increased siltation and turbidity caused by the introduction of sediments into the stream. Construction methods are summarized in section 2.4.1.1 and activities potentially impacting water quality are discussed in detail in section 4.3.2.3. Potential impacts on aquatic resources due to the road modifications and bridge replacement include the following:

- direct impacts on fish during salvage activities due to handling and electrofishing, if required at the bridge site;
- displacement of fish during demolition and construction; and
- increased turbidity and suspended sediment levels during pile removal and abutment construction;
- accidental spills or leaks of toxic materials (e.g., uncured concrete, demolition debris, equipment lubricants or fuel) during demolition and construction.

To minimize potential impacts on fish during salvage activities, if required, all salvage activities would occur within the in-water work window and would be performed or supervised by qualified fisheries biologists and would operate under the NMFS's and ODFW's fish salvage guidelines. In addition, all work would be performed under an ODFW/NMFS scientific collection permit and resource agency personnel would be invited to participate or oversee the operations.

Potential impacts on aquatic resources due to displacement during construction activities are described in section 4.5.2.1. The potential for increased turbidity and suspended sediment levels as well as accidental spills or leaks associated with road modifications and bridge replacement would be minimized through implementation of NorthernStar's terminal ESC Plan and the bridge demolition and construction BMPs described in section 4.3.2.3.

Railroad Realignment

As described in section 2.4.1.1, NorthernStar would remove a 4,200-foot-long portion of the existing PWR line and construct a new segment outside the boundary of the proposed LNG terminal. The realigned railroad tracks would be constructed parallel to Hunt Creek for approximately 2,000 feet. After realignment of the railroad tracks, the creek and the edge of the railroad right-of-way would be between 50 and 400 feet apart for most of the 2,000 feet; however, for about 50 feet, the edge of the railroad right-of-way and Hunt Creek would be less than 50 feet apart. NorthernStar expects that a minimum 30-foot undeveloped buffer between the railroad right-of-way and the creek could be maintained in this area. Realignment of the railroad tracks could potentially impact salmonids and other aquatic resources in lower Hunt Creek through increased siltation and turbidity caused by the introduction of sediments into the stream. However, to avoid or minimize impacts on aquatic resources within Hunt Creek resulting from realignment of the railroad tracks, NorthernStar would restore the natural upland vegetative community by installing native vegetation within the railroad right-of-way as described in section 4.4.2.2 and by implementing its terminal ESC Plan.

Over-water Structures

As described in section 2.3, over-water structures associated with the marine berth would occupy approximately 1.0 acre over the Columbia River. Of this, structures would be located over approximately 0.5 acre of shallow water habitat. These structures have the potential to impact aquatic resources through changes in species behavior and the associated increased vulnerability of sensitive species to predation. In addition, the marine berth could indirectly impact aquatic resources through alterations to water quality, including changes in light, temperature, and nutrient levels directly beneath the docks.

An assessment of over 60 studies by Simenstad et al. (1999) found evidence that juvenile salmon react to shadows and other artifacts in the shoreline environment created by over-water structures. While changes in light from over-water structures have been shown to affect migration behavior in juvenile salmon, quantitative information on the significance of these behavioral responses is not available (Simenstad et al., 1999; Carrasquero, 2001).

Because juvenile salmonids (especially Chinook salmon) tend to migrate through shallow-water habitats along shorelines, over-water structures can impact migration through and use of potential habitat. Simenstad et al. (1999) found that juvenile salmon use both natural refuge and shaded areas as refuge, but they generally migrate along the edges of these areas, rather than entering them. However, in response to predators, they will seek refuge within shaded areas. Juvenile salmon have been observed to become “confused” upon encountering over-water structures due to the conflict between their preference to migrate through nearshore habitats and their avoidance of shaded areas. This confusion results in behavioral changes including splitting into smaller schools and seeking alternate pathways, which can ultimately cause a delay in migration (Simenstad, et al., 1999).

Recognized predators of juvenile salmonids in the lower Columbia River include bass, shad, lampreys, northern pikeminnow, and birds. Although numerous studies and anecdotal information from sport fisherman have suggested that docks and piers attract fish, studies have not been conducted to determine whether over-water structures actually increase the concentration of predatory fish, birds, or marine mammals (Simenstad et al., 1999; Carrasquero, 2001).

Changes in water quality within the shaded area created by the marine berth could reduce habitat quality for aquatic resources by altering the rate of photosynthesis, plant distribution, and indirectly by altering prey species composition and survival (Thom et al., 1997; Olson et al., 1996; Thom and Shreffler, 1996). NorthernStar would mitigate for reduced habitat quality at the berth and maneuvering area

through restoration of several times as much area of high quality habitat at the Svensen Island and Hunt Creek Mitigation Sites (see *Mitigation Measures*, below).

Water Appropriation and Discharge

During construction and operation of the proposed LNG terminal, NorthernStar would appropriate water from the Columbia River for multiple uses. Table 4.3.1-1 describes the proposed water appropriations and discharges associated with the proposed project. Potential impacts associated with water appropriation include entrainment and impingement of fish and reduced downstream flows. Potential impacts on aquatic resources due to discharges would be limited to changes in water quality.

Entrainment and Impingement

NorthernStar proposes to obtain water from the Columbia River through the terminal's permanent surface water intake for hydrostatic testing of the LNG storage tanks and pipeline, soil compaction and ground improvements, fire suppression system testing, and personal/sanitary use (see figure 2.1.3-3). NorthernStar would acquire the necessary permits from the ODWR before withdrawing water, including specific approvals from applicable resource agencies. Impacts on fish associated with surface water withdrawal would be minimized by using modern fish screening technology, which has been used within much of the Columbia River since the 1970s.

All intakes at the proposed LNG terminal that withdraw water from the Columbia River would be screened to minimize the likelihood of entrainment and impingement of juvenile fish in accordance with the ODFW and NMFS regulations and fish design criteria. The screen designs proposed by NorthernStar have been reviewed and approved by the NMFS. The fish screen criteria proposed for the temporary water intake is based on the NMFS, Juvenile Fish Screen Criteria and addendum as well as the Fish Screening Criteria for Anadromous Salmon (NMFS, 1995a; 1996; 1997). All the criteria specify the approach velocity and screen mesh opening sizes and considers both the presence and absence of fry-sized salmonids.

There are two locations proposed for water intake. The first location is the temporary surface water intake and pump that would be used to supply water for vibroflotation activities. A diesel-powered pump would divert water from the Columbia River at a maximum rate of 100 gpm (0.36 cfs). The temporary water intake would be located approximately 100 feet offshore, at a depth of 2 feet or more, meeting NMFS criteria. It would be equipped with a passive fish screen that complies with the ODFW regulations and NMFS fish screen design criteria. The fish screen would be designed to exclude salmonid fry; per the criteria, the screen mesh openings would not exceed 3/32 inch (2.38 mm) for a woven wire or perforated plate screen, or 0.0689 inch (1.75 mm) for a profile wire screen, with a minimum 27 percent open area. The screen would be mounted parallel with flow in the river and aligned with the adjacent bankline. The maximum approach velocity at the screen would be 0.2 ft/s. The proposed system meets the criteria for using a passive screen, including oversizing the screen to eliminate debris impingement (the effective screen area of NorthernStar's proposed M-L130 Pump-Rite model is nearly five times the required effective screen size). If debris is collected on the screen itself, debris would be physically removed by construction staff over the 3- to 4-month time frame the intake would be in use.

The second water withdrawal location would be the LNG terminal's permanent surface water intake and firewater pumping station, which would be used during construction to supply water for the hydrostatic testing of the LNG storage tanks. Construction of the LNG terminal would be scheduled so that the permanent water intake and pumping station would be online early enough in the construction period for use as a temporary water withdrawal location for hydrostatic testing of the LNG tanks. The firewater pumps would be mounted on the dock several feet below the mean low water elevation. The pumping station would be equipped with two 400 horsepower pumps, an electric primary pump, and a

diesel backup pump. The pumps would not operate simultaneously. The maximum rate of discharge of either pump would be 4,400 gpm (9.8 cfs) (GSI, 2006b).

The second water withdrawal location (permanent water intake), would be equipped with active (self-cleaning) fish screens that comply with the ODFW regulations and NMFS fish screen design criteria. The fish screen would be designed to exclude salmonid fry; per the criteria, the screen mesh openings would not exceed 3/32 inch (2.38 mm) for a woven wire or perforated plate screen, or 0.0689 inch (1.75 mm) for a profile wire screen, with a minimum 27 percent open area. The intake would be mounted parallel with flow in the river and aligned with the adjacent bankline. The current intake design assumes a maximum approach velocity at the screen of 0.33 ft/s. The proposed intake system would use an active, self-cleaning air backwash system (called Hydroburst) to clean debris and scour growth from the screens. The frequency with which the air backwash is used would depend on the debris load in the water column and the growth rate of algae and other sessile organisms.

In its May 11, 2007 letter to the FERC, the NMFS stated that flows need to be mapped post-construction to verify that screen velocities are acceptable. To ensure that screen velocities would comply with ODFW and NMFS fish screen criteria, **we recommend that:**

- **NorthernStar should conduct post-installation water flow mapping through all intake screens at the LNG terminal, and develop and implement a monitoring program to assess the effects of impingement and entrainment from use of the screened water supply system on juvenile salmonids during terminal operations. The monitoring program and water flow mapping plans should be developed in consultation with the NMFS and ODFW and, as appropriate, incorporate adaptive management strategies to identify and mitigate any adverse effects specifically associated with the project. The final monitoring program and water flow mapping results, as well as any agency comments, should be filed with the Secretary for the review and written approval of the Director of OEP prior to operation of the screens. In addition, NorthernStar should provide annual reports to both the FERC and NMFS regarding the efficacy of the screened water intake system, which would identify any problems and address how such problems would be rectified.**

In addition, water would be appropriated by LNG carriers during unloading as ballast and to cool the engines generating power for the offloading pumps and other onboard systems (see section 2.1.1.5). To minimize entrainment and impingement of juvenile fish during ballast and cooling water intake, NorthernStar would construct a system capable of delivering filtered water to the LNG carrier. NorthernStar would offer contract incentives to the LNG suppliers to retrofit LNG carriers to connect with the wharf filtered water supply so that all water withdrawn from the Columbia River would be done via screened intakes constructed by NorthernStar at the LNG terminal. Water supplied to the carriers via this intake system would be first used to cool the engines and then used to fill the ballast tanks to minimize the total intake and avoid discharging warm water into the Columbia River. In rare instances when ballast tanks fill before the need for shore-based cooling water is over, the ballast water would be circulated through the engines for cooling after the shore-based water supply is turned off and until the ship is ready to leave the wharf. NorthernStar would design the filtered water system to minimize entrainment and impingement of juvenile fish.

To ensure that impacts associated with entrainment and impingement are minimized, we recommended in the draft EIS that NorthernStar prepare a plan to ensure that only LNG carriers that have been retrofitted to use the screened water supply system at the berth are allowed to unload cargo at the Bradwood Landing LNG terminal. As discussed in section 4.3.2.3, NorthernStar has stated that due to changes in market conditions since issuance of the draft EIS, LNG carriers may arrive at the terminal without the necessary retrofitting in place to allow the use of the screened water supply system. The

FERC received numerous comments on the draft EIS related to potential impacts on aquatic resources in the event that the screened water intake system is not functional or would not be used for a period of time. We conducted a preliminary analysis of the number of out-migrating juvenile salmonids that would be entrained by LNG carriers at the wharf without the use of the filtered water supply system and NMFS-approved screens. The preliminary analysis, discussed below, indicates that a substantial number of migrating juvenile salmonids could be entrained, particularly during peak out-migrating periods (i.e., March through August).

Our preliminary analysis included: 1) a determination of the area near the intake which would be subject to velocities likely to result in impingement or entrainment of juvenile salmonids, and consideration of how that area relates to the terminal and LNG carrier's water intake locations; 2) an investigation of the widely varying migration behaviors of juvenile salmonids by species, which result in an array of spatial and temporal distributions; 3) an estimation of the number of juvenile salmonids out-migrating by species and season; and 4) a breakdown of the frequency with which LNG carriers would be expected to operate their intakes. We assumed that fish with swimming speeds greater than the intake velocity can avoid impingement. Swimming speed is estimated to be about 0.5 body length per second (Durbin et al., 1981). Thus, a fish 7-inches-long or larger would be able to avoid impingement or entrainment. However, smaller sized juveniles and non-motile larvae and eggs may not be able to avoid the intake, and thus are more susceptible to entrainment. Entrained organisms would be subjected to physical stress and pressure changes as a result of abrasion or contact with screens and pump impellers. Physical damage has not been well documented, but is assumed to injure entrained ichthyoplankton (Cada, 1990; Mayhew et al., 2000) and other water column organisms. Pressure changes, such as a sudden decrease in ambient pressure of 40 percent or more of the acclimation pressure, might burst swim bladders, thus resulting in the mortality of fish larvae that have developed swim bladders (Cada, 1990).

The preliminary analysis provided a rough estimate of the potential impacts on juvenile fish associated with cooling and ballast water intakes, and the estimates generated to this point require further refinement prior to incorporation into the FERC's revised BA and EFH Assessment. Future analysis may consider a variety of other factors that could widely influence the final values, including: 1) fish behaviors such as avoidance or attraction, diurnal peaks in migration; 2) fish movements lateral to stream flow; 3) migration patterns around Puget Island; 4) an account of all watersheds contributing juvenile salmonids that migrate past the wharf; 5) ESU and DPS specific migratory quantities and characteristics; and 6) velocities occurring near the LNG carrier intakes for different designs of LNG carriers.

NorthernStar has stated that it would continue to offer incentive-based contractual agreements for carriers to accommodate the screened water supply system, but it could not guarantee 100 percent use of the proposed system. Instead, NorthernStar proposes to develop a performance standard for the temperature of all cooling water discharges at the wharf and a performance standard for entrainment of juvenile fish at the wharf. Both performance standards would have a monitoring component. To date, we have not been provided any information on these potential performance standards. To ensure impacts to water quality are minimized, we are recommending in section 4.3.2.3 that NorthernStar develop performance standards for water temperature impacts and biocide use associated with LNG carrier water intakes and discharges. However, a performance standard for entrainment and impingement impacts could not appropriately mitigate the routine removal of 20 to 50 million gallons of unscreened water per LNG carrier visit at the Bradwood Landing terminal.

We compared NorthernStar's potential entrainment and impingement impacts to baseline conditions to analyze the potential for significant cumulative impacts. We estimated that roughly 1,800 commercial ships dock at various lower Columbia River ports annually. We note that no screening of water intakes to protect aquatic resources is currently conducted for any ships docked at Columbia River ports. About 50 percent of the commercial marine traffic on the Columbia River stops at Portland,

Oregon, 18 percent at Vancouver, Washington, and 10 percent at Longview, Washington (Merchant Exchange of Portland, 2007 Annual Report). Considering the ballast requirements of the various sized ships calling on those ports (e.g., container types, oil tankers, bulk carriers) and assuming that each commercial marine vessel is taking on ballast water, the combined withdrawal could reach 10.4 billion gallons of ballast water per year. We also considered the subset of larger container and oil tankers which are most comparable in size to the typical LNG carrier, which make up about 16 percent of the marine traffic on the lower Columbia River. We estimated that these carriers withdraw up to a total of 3.2 billion gallons for ballast per year. In comparison, the typical LNG carriers berthed at the Bradwood Landing terminal would intake approximately 3.1 billion gallons of ballast water per year. Therefore, in comparison to baseline conditions, we estimate that the Bradwood Landing Project could result in a roughly 30 percent increase in total ballast water withdrawals compared to current commercial shipping on the Columbia River, and would nearly double current ballast water withdrawals by large container ships and tankers. We were unable to find any relevant data for the amount of water that commercial ships currently operating in the Columbia River take on for engine cooling water, for comparative purposes.

We conclude that impacts on sensitive aquatic resources would not be adequately mitigated to a less than significant level without a screening mechanism that minimizes entrainment and impingement of sensitive species of juvenile fish. To ensure that impacts on sensitive aquatic resources from LNG carrier water appropriations and discharges at the LNG terminal would be appropriately mitigated, **we recommend that:**

- **Within 30 days after the issuance of the final EIS, NorthernStar should:**
 - a. **prepare a plan that outlines how NorthernStar would ensure only LNG carriers that are retrofitted to use the proposed screened water supply system at the wharf are allowed to unload cargo at the Bradwood Landing terminal. The plan should include a method of certifying to the FERC, in advance of a LNG carrier's initial call to the Bradwood Landing terminal, that the LNG carrier has been retrofitted to utilize NorthernStar's screened water intake system; or**
 - b. **develop a plan for delivering screened engine cooling and ballast water to LNG carriers at the Bradwood Landing terminal that does not require carrier retrofitting.**

The proposed screened water supply system design plan should include monitoring, reporting, and adaptive management strategies to assure the system's efficacy at minimizing entrainment and impingement of sensitive species of juvenile fish.

The screened water system design and performance measures would be vetted during the formal consultation process and continuing consultations with the NMFS, ODFW, and other appropriate resource agencies. **We recommend that:**

- **Prior to initial site preparation at the LNG terminal, NorthernStar should file the final screened water system design plans and performance standards, along with NMFS comments on the plans and standards, with the Secretary for review and written approval by the Director of OEP.**

Reduced Downstream Flows

River flows are crucial to the migration of anadromous fish on their journey from spawning areas to the ocean. Historically, the Columbia River provided higher flow during the spring and fall, which coincided with juvenile salmon migration periods. The increased flow helped juvenile salmon migrate downstream and out into the ocean. Over time, the addition of dams, impoundments, and water diversions along the Columbia River has led to a more constant flow pattern throughout the entire year by limiting the high and low flows below the dams.

The USGS maintains a gauging station at Beaver Army Terminal, located at CRM 53.8. Data obtained from this station is available for the period between 1992 and 2003. During this period, the average annual mean streamflow was 233,575 cfs, with a high of 329,700 cfs in 1997, and a low of 145,200 cfs in 2001 (USGS, 2006). Water withdrawals associated with construction and operation of the LNG terminal would be a fraction of these rates (i.e., less than 80 cfs). Although reduced downstream flows as a result of the proposed project are expected, the reduction would not be significant.

Changes in Water Quality Associated with Discharge

Following hydrostatic testing of the LNG storage tanks, water would be discharged at about 5,000 gpm to the Columbia River at the LNG terminal site. This discharge has the potential to impact aquatic species due to localized erosion and temporary changes in the chemical characteristics of water near the outfall. Construction impacts associated with increased erosion and suspended sediment levels would be minimized by discharging water through a temporary outfall located about 300 feet offshore that would be diffused or armored to avoid localized erosion. Changes in the chemical characteristics in the vicinity of the outfall could occur if chlorinated water is discharged to the Columbia River. Water appropriated for hydrostatic testing of the LNG storage tanks would be tested for bacteria before use. If bacteria levels are high enough to cause corrosion in the tanks, the water would be chlorinated before testing. To prevent chlorinated water from entering the Columbia River, all hydrostatic test water would be sampled and analyzed before discharge and dechlorinated as necessary.

Water appropriated for hydrostatic testing of the pipeline would be discharged to an upland area near the pipeline crossing of the Columbia River using appropriate filtering techniques. The water would be discharged at an approximate rate of 1,000 gpm and would not be chemically treated. All discharges would be in compliance with NorthernStar's ODEQ water discharge permit and would not be expected to impact fish.

During operation of the facility, water appropriated for testing of the fire suppression system would be discharged to the Columbia River via elevated fire monitors at the end of the dock. We do not anticipate any scour as a result of this testing because the elevated fire monitors would be located over 300 feet from the shoreline and would discharge in an area with an approximate water depth of 42 feet. Fire suppression test water would not come in contact with any source of contamination onsite prior to discharge.

While LNG carriers are docked at the LNG terminal wharf, they may discharge cooling water if they are not modified to discharge cooling water into the ballast tanks. As discussed in section 4.3.2.3, engine cooling water discharged to the Columbia River could initially be 19.4 °F higher than ambient water temperatures (ranging between 42 °F and 68 °F in Astoria, Oregon). Maximum water temperatures ranging from 71.6 °F to 75.2 °F limit the distribution of many salmonids. Potential impacts on aquatic resources due to temperature increases are discussed further above (see *Habitat Modification, LNG Terminal*). In addition, cooling water for the LNG carriers may be injected with a low dose of biocide (expected to be sodium hypochlorite) to prevent the growth of marine organisms. Discharge of the

residual chlorine concentration is not expected to affect aquatic resources outside of the mixing zone because of the relatively low concentration of sodium hypochlorite that may be present in the discharge, and mixing upon discharge would occur rapidly due to the volume of water in Columbia River and mixing by the tides and currents. However, due to the presence of federally listed species at the LNG terminal site, we have recommended in section 4.3.2.3 (see *Entrainment and Impingement*) that NorthernStar conduct additional modeling and develop mandatory performance standards for water temperature and biocide use at the LNG carrier wharf. The performance standards and resulting impacts on federally listed species and EFH at the LNG terminal wharf would be further analyzed in our revised BA and EFH Assessment.

LNG Terminal Lighting

Construction

The Bradwood Landing Project would necessitate the installation of temporary lighting to facilitate construction activities during evening hours as well as permanent lighting to meet operational safety and security requirements. The response of fish to artificial lights can be quite variable depending on a number of factors. Specific responses by fish to light seem dependent on the intensity of the light as well as the species and age-class of the fish (Hoar et al., 1957). Schools of juvenile chum salmon show a marked preference for light while juvenile sockeye retreat to darker areas. Juvenile coho are indifferent to light of moderately high intensities but become inactive in light of very low intensities. While the responses of fish to light are sometimes based on innate behaviors, in other cases, these responses may be based on the presence of prey items. For example, artificial lighting is documented to decrease the daily vertical migration of zooplankton that come to the surface to feed on algae under the cover of darkness.

To avoid and minimize lighting effects during construction, lights would be shielded and directed as needed to illuminate the work areas and meet safety requirements, but to avoid extending off site unnecessarily. Safety, security, and maintenance of the construction schedule would be the primary considerations for construction lighting. Due to the very dynamic nature of large-scale construction and limitations on dictating equipment to contractors, NorthernStar has not defined specific lighting plans for construction. However, it has stated that lights would be unlikely to shine directly at the water for any longer than brief moments during construction.

Operation

Based on NorthernStar's *Lighting Plan for the Bradwood Landing LNG Terminal* (Lighting Plan), lighting sources at the LNG terminal would be designed to provide a minimum of 22 Lux of light intensity on all illuminated areas from sunset to sunrise.¹⁴ Minimum light intensities were determined by NorthernStar in accordance with the state-of-practice industry standards as specified in ANSI/IESNA RP-07-01. General lighting of outdoor open areas, roads and access ways, and the berth would be provided by pulse-start metal halide lights, high pressure sodium lamps, or compact fluorescent lamps in fixtures that use multiple lamps. The fixtures would be mounted on masts or off structural supports. All lighting fittings would be supplied with integral control gear. Before mitigation, metal halide lights would contribute more to the total light levels than high pressure sodium lamps or compact fluorescent lamps. However, because metal halides can be shielded with hoods and shields, stray light could be significantly reduced. Operational lighting impacts on aquatic species would be similar to construction lighting impacts described above, but would occur year-round for the life of the project.

¹⁴ NorthernStar submitted its Lighting Plan for the Bradwood Landing Terminal as part of its response to the NMFS' May 11, 2007 request for additional information to the FERC on July 6, 2007. This document is available for viewing by the public on the FERC's Internet web page at www.ferc.gov, through the eLibrary link, selecting "General Search," entering the docket number minus the last three digits (i.e., CP06-365), and putting in the proper date range.

To minimize the potential impact on salmonids and other aquatic species from operational lighting, NorthernStar's Lighting Plan includes the use of directed lighting, diffusers, lenses, and shields where appropriate to reduce glare and light pollution. For example, tilted lights (e.g., bracket and stanchion mounted lights) would be directed toward the center of the facility to minimize stray light. In addition, hoods would be specified where possible for lights on the facility exterior (except for navigation aids and security lights) in order to focus light where needed for operational purposes, while minimizing stray light.

To address concerns raised by the NMFS, NorthernStar is conducting additional analysis of the impacts of terminal lighting on salmonids as part of the consultation process. Due to the presence of high-quality habitats and both federally and state-listed species in the vicinity of the LNG terminal, additional measures are necessary to minimize impacts from terminal lighting on wildlife and aquatic resources. Therefore, **we recommend that:**

- **NorthernStar should continue to consult with the NMFS, FWS, ODFW, and other appropriate agencies regarding revisions to its Lighting Plan. NorthernStar should file its final Lighting Plan along with agency comments with the Secretary for review and written approval by the Director of OEP, prior to operation of the LNG terminal.**

Blasting

Blasting may occur during construction of the LNG terminal at the quarry near the southwest corner of the site approximately 800 feet from the Columbia River. The location of the quarry is shown on figure 2.3.2-1. Potential impacts on aquatic resources from blasting at the LNG terminal would be similar to those described as a result of pile driving and include changes in behavior, decreased perception, and damage to body tissue. Published blasting data (Leonard Charles and Associates, 2005) recorded blasting noise similar to what would be expected at the Bradwood Landing site as 118 dB at a distance of 550 feet from the blast site. Using logarithmic spreading, the sound pressure level would attenuate to 100 dB at a distance of 4,370 feet from the source, or to 115 dB 800 feet northeast of the quarry at the Columbia River. Therefore, we estimate the area experiencing 100 dB blast overpressure would encompass the Columbia River. Special blasting techniques, such as charge weight control, blast pattern design, use of stemming material, depth of the charge, and cover material are typically used to control the blasting noise.

As previously discussed, the estimated noise in air at the shore of the Columbia River from blasting at the quarry would be 115 dB. As described above (see *In-water Construction, Pile Driving*), the equivalent underwater noise would be 141 dB re: 1 μ Pa. Blasting generally emits low frequency sound waves lasting 300 to 1,000 milliseconds (Aggregate Industries, 2005). Although this would generally not be considered impulse noise, the corresponding impulse pressure values would be expected to be less than 141 dB_{rms}. Therefore we do not anticipate that the noise thresholds for pinnipeds and salmonids (160dB_{rms} and 150 dB_{rms}, respectively) would be exceeded as a result of the blasting at the LNG terminal site.

Seal bombs, which have historically been used to prevent pinnipeds from feeding around fishing gear, create explosions in the range of 220 dB re 1 μ Pa (peak) (Richardson et al., 1995). The estimated maximum underwater noise exposure to pinnipeds from blasting at the Bradwood quarry would be less than such explosions. Although pinnipeds moving through the area would detect the blast noise and may avoid the area, after continued exposure to the blasting, the avoidance would be expected to wane (Richardson et al., 1995). Blasting at the quarry is not expected to result in adverse impacts on either pinnipeds or salmonids in the Columbia River and Clifton Channel. No underwater blasting is planned for this site.

Accidental Spills or Leaks of Hazardous Materials

For any large construction project, there is the potential for spills or leaks of fuels or hazardous materials from storage containers, equipment working in or near streams, and fuel transfers. Any spill of fuel or hazardous liquid that reaches a waterbody would be detrimental to water quality. The chemicals released during spills could have acute, direct effects on fish, or could have indirect effects such as altered behavior, changes in physiological processes, or changes in food sources. Fish could also be killed if a large volume of fuel or hazardous liquid is spilled into a waterbody. Ingestion of large numbers of contaminated fish could affect primary and secondary fish predators in the food chain.

To minimize the potential for spills, NorthernStar prepared a terminal ESC Plan that includes spill prevention and response procedures. NorthernStar's implementation of this plan would minimize the potential for and the impacts of any spill near surface waters. Specific measures in this plan include prohibiting liquid transfer, vehicle and equipment washing, and refueling within 100 feet of waterbodies and specific steps to be followed to control, contain, and clean up any spill that occurs.

LNG Terminal Operations

Additional terminal operations activities that could potentially impact fish and fish habitat include stormwater runoff, maintenance dredging, the routine discharge of condensate water from the SCVs, and increased noise.

Stormwater Runoff

About 40 percent (16 acres) of the LNG terminal site would be comprised of impervious surface (roadway, rooftop, enclosed structures, and LNG facilities). The remainder of the site would either be landscaping or a loosely packed gravel surface overlying dredged materials. As described in NorthernStar's *Stormwater Management Plan for Removal/Fill Permit Applications* (see section 4.3.1.3), soils at the site have high infiltration rates (at least 14 inches per hour), which would result in rain infiltrating directly into the ground except during major storms. Stormwater runoff that does not infiltrate directly into the ground would be routed to two drainage basins within the LNG terminal site. Rain falling on roofs and paved areas would also be conveyed to the drainage basins that would have capacity to hold runoff from at least a 100-year storm event. NorthernStar expects that all stormwater would be managed on site via infiltration. Therefore, adverse impacts on aquatic resources resulting from stormwater runoff are not anticipated.

Maintenance Dredging

As described in section 2.7.2, NorthernStar expects to dredge about 80,000 cubic yards of material from the ship berth and maneuvering area approximately every 2 to 4 years. NorthernStar proposes to place material from maintenance dredging at the Wahkiakum County Sand Pit site. A specific model has not been run to determine the anticipated turbidity levels resulting from placement of dredged materials at the Wahkiakum County Sand Pit site. However, as described in section 4.3.2.3, given the large grain size of the sediments, the materials are expected to rapidly settle out of the water and water quality impacts would be similar to that at the LNG terminal site during dredging operations. Maintenance dredging impacts on aquatic species would be similar to the dredging of the ship berth and maneuvering area, but would occur intermittently during the operation of the LNG terminal. Based on the recolonization rates described above (see *Dredging, Removal of Benthic Organisms*), the frequency of maintenance dredging may result in permanent alterations in the benthic community within the berth and maneuvering area.

Routine Discharge of Condensate Water from the SCVs

Water is produced as a by-product in the LNG vaporization process proposed by NorthernStar. As discussed in section 4.3.2.3, the SCVs would generate up to 160 gpm of condensate water during operation of the LNG terminal. NorthernStar proposes to discharge the SCV water to the Columbia River under an NPDES permit. Fish could be affected by this discharge due to temporary changes in water quality including increased acidity, increased temperature, and increased dissolved solids.

The pH of the water bath in an SCV is typically maintained at 5.6 standard units and the temperature of the bath is maintained between 55 °F and 65 °F. Before discharge, the pH of the SCV discharge water would be increased in a neutralization tank. An allowable discharge pH would be established during the NPDES permit review process, thereby mitigating potential impacts on aquatic resources.

The average water temperature in the Columbia River measured in Astoria between December 2005 and 2006 was 54.4 °F, ranging between 42 °F and 68 °F, depending on the season (NOAA National Oceanographic Data Center, 2006). The SCV discharge water would be 68 °F, which is generally warmer than the ambient water temperatures but would not exceed the temperature standard of 68 °F for fish rearing and migration (ODEQ, 2003). Plumes of warmer water can directly impact fish that come into contact with the water. Biological processes for coldwater fish tend to speed up and sensory processes slow down as water temperatures increase; immune systems may become compromised, and warmer waters may have reduced levels of dissolved oxygen, among other effects (Bjornn and Reiser, 1991). Warmwater plumes may also cause avoidance, requiring fish to move to other locations and exposing them to predation and additional consumption of their energy resources (NMFS, 2005a). Studies have found that adult survival rates in Columbia River salmonids are correlated with smolt weight at ocean migration. Since smolt weight is a function of energy used versus energy consumed, the less energy needed to survive, the more is available to build fat and energy reserves (Fresh et al., 2004). As described in detail in section 4.3.2.3, given the volume of SCV discharge in relation to the volume of flow in the river, we anticipate that water temperatures near the outfall would rapidly return to ambient conditions, thereby limiting the potential to adversely impact aquatic species.

The total dissolved solids content of condensate would be about 10 times the concentration in the river (there is a guideline standard of 500 mg/L). Because the SCV water would be discharged using an outfall/diffuser system mounted below the water level near the eastern end of the dock to take advantage of better water circulation in the mainstem of the Columbia River, it is expected that the discharge would not have a measurable effect on the total dissolved solids content outside a mixing zone that extends about 10 feet from the diffuser. Through proper management of SCV water discharges, potential impacts on aquatic resources due to increased dissolved solids would be minimal.

Operational Acoustic Effects

Maintenance dredging activities and LNG carrier and tug operations along the LNG carrier transit route and at the LNG terminal would generate underwater sounds pressure levels that could elicit responses in marine organisms. The intensity of the sound pressure levels from vessel traffic and dredging activities can be quite variable. However, sound pressure levels are generally in the range of 112 to 160 dB (re: 1 µPa), intensities that may influence organism behaviors or perceptions but are not great enough to cause physiological damage (Richardson et al., 1995; NMFS, 2005a).

Operational acoustic impacts would depend upon the specific schedule, duration, and type of vessel traffic and the timing and extent of maintenance dredging. Generally, these impacts would be

behavioral and perceptual, and not physiological in nature as fish would tend to avoid the area during periods of high noise output.

Mitigation Measures

Project design, construction, and operation plans have been modified to avoid or minimize impacts on aquatic resources. These efforts would be ongoing during construction in order to capitalize on avoidance and minimization opportunities that cannot be predicted. However, both direct and indirect impacts on aquatic resources would result from construction and operation of the proposed project.

Following construction of the LNG terminal, habitat and ecosystem function would be restored in place. Permanent impacts on aquatic resources would be mitigated by restoring habitat with similar ecological function in areas substantially larger than that lost to permanent impacts. However, although compensatory mitigation actions would restore habitat and have long-term benefits to wetlands, estuarine ecosystems, and habitat for salmonids in general, there would be short-term adverse effects and longer term adverse effects on some non-target species. In terms of overall ecosystem health, these trade-offs are considered appropriate and valuable enough to more than balance the cost of the adverse effects.

NorthernStar identified a number of sites in the general project area that would be set aside and/or developed as compensatory mitigation. Mitigation for impacts on aquatic resources at the Svensen Island and Hunt Creek Mitigation Sites are summarized below. In addition, the Peterson Point Mitigation Site would include restoration of riparian habitats, thereby providing additional benefits to aquatic resources. This mitigation site is discussed in section 4.5.2.3. NorthernStar has also developed an SEI that would be implemented throughout the life of the project. The SEI is described in detail in section 4.6.2.2.

The FERC received numerous comments stating that the mitigation proposed by NorthernStar does not adequately compensate for impacts on aquatic resources associated with the project. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. To ensure that the mitigation proposed for the Bradwood Landing Project adequately compensates for project-related impacts, we have recommended that NorthernStar continue to consult with the appropriate natural resource agencies to finalize its Compensatory Mitigation Plan. The final Compensatory Mitigation Plan should be filed along with agency comments and applicable approvals with the Secretary prior to construction of the project.

Svensen Island Mitigation Sites

As discussed in section 4.4.1.2, the Svensen Island Mitigation Sites would be the primary wetland mitigation sites in Oregon and are located about 14 miles downstream of the proposed Bradwood Landing LNG terminal in Clatsop County, Oregon (see figure 2.1.5-1). For over 100 years, Svensen Island has been protected and separated from the Columbia River by a surrounding dike (an 1868 map shows the dike). The area inside the dike has been agricultural land since the dikes were constructed. Two cross dikes divide the island into three distinct areas. NorthernStar proposes to provide mitigation at two of the three areas, lower Svensen Island and middle Svensen Island. Existing conditions and a list of mitigation measures that would be implemented at these two areas are discussed in the following sections.

Lower Svensen Island

The westernmost section of the island (lower Svensen Island, which includes more than half of the island acreage) was flooded when the dike breached at the northwestern tip of the island in December 2003. Since then, twice daily high tides flood about 170 acres inside the dike, and tidal marsh has reestablished itself. A high percentage of the flooded area is now occupied by a diverse array of marsh species, mostly native, and is a fish and wildlife haven. Since the location is upriver of the area of

saltwater intrusion into the river, the marsh is a freshwater marsh. In addition to the main channel now bisecting the site, many smaller remnant channels exist. New channels stemming from the main channel also appear to be forming. At low tide, the eastern portion of the site is saturated, but only certain areas maintain standing water. A culvert in the northeastern part of the site prevents water from draining properly, and may strand fish at low tide.

Tidal marshes are the most productive fish habitats of the lower Columbia River estuary. Marsh vegetation, such as that found within the lower Svensen Island area, may produce an average annual standing crop of 5 tons per hectare. The resulting plant detritus can sustain a large and diverse population of invertebrates. Some of these small crustaceans and aquatic insects are an important food source for juvenile salmon. The tidal marsh includes dendritic channels that provide excellent fish habitat. Large numbers of juvenile Chinook and chum salmon are present within tidal channels of the marsh, and other species, such as starry flounder, likely use these areas as well. Chinook fry may rear in the marsh for up to a month. During that time, Chinook fry would nearly double in size and quadruple their weight as they feed on the abundant invertebrates. The protected and turbid water of the lower Svensen Island marsh also offers a certain amount of protection against predators. At present, fish have access to the site through the channel at the northwestern breach location and at the culvert that lost its tidegate. The site serves as a protected area for salmon rearing and may serve as a refuge from storm flows.

Wildlife observed at the site includes numerous shorebirds and waterfowl, in addition to raptors. Also, there have been recent reports of hundreds of red-legged frogs and thousands of Pacific chorus frogs during the spring and early summer. This provides some indication that common predators, such as bass and bullfrogs, are not prevalent within the lower Svensen Island area.

To mitigate for impacts on aquatic resources and wetlands due to the proposed project, NorthernStar has proposed to preserve lower Svensen Island and would also implement the following restoration activities:

- control invasive weeds;
- add anchored LWD at tidal channels as fish habitat features;
- further restore fish accessibility by removing two remaining tidegates from existing culverts;
- further restore fish habitat value by removing several (up to eight) remaining culverts on former farm roads that block fish escape with receding tides;
- further restore wetland and riparian habitat by removing remaining buildings and facilities so that plants can grow (possibly adding soil); and
- remove remaining fuel tanks that might pose a risk to aquatic organisms.

Middle Svensen Island

Middle Svensen Island includes both uplands and wetlands dominated by a mix of pasture grasses and invasive herbaceous species with shrubs (such as Himalayan blackberry and red elderberry) along some of the ditch spoil piles and the dikes. Because middle Svensen Island is generally isolated from the river and lower Svensen Island, it currently provides no habitat for fish. The area has seasonally saturated wetlands that have no surface water interconnection with the Columbia River except through tidegates on drainage ditches that preclude fish passage.

To mitigate for impacts on aquatic resources and wetlands due to the proposed project, NorthernStar has proposed implementing the following mitigation measures at middle Svensen Island:

- remove three tidegates on the south side of the island;
- breach the northern dike near the cross-dike between middle and lower Svensen Island (the above actions would flood about 65 acres at normal high tide);
- provide a large culvert connection through the cross-dike to facilitate wetland vegetation seed transport from lower to middle Svensen Island to speed wetland establishment;
- fill or reconfigure existing drainage ditches;
- excavate new low-tide channels;
- place some excavated material along selected dike areas to facilitate growth of shrubs and trees to be planted;
- add anchored LWD at tidal channels as fish habitat features; and
- control invasive weeds.

NorthernStar has an exclusive option to purchase a majority of Svensen Island. The habitat values would be maintained under a stewardship agreement with a land trust, which would be funded by NorthernStar.

Hunt Creek Mitigation Site

The Hunt Creek Mitigation Site is located adjacent to the proposed LNG terminal (see figure 2.1.5-1). The portion of Hunt Creek adjacent to the LNG terminal is designated EFH and provides spawning and rearing habitat for the Lower Columbia River coho salmon ESU. In addition, the confluence of Hunt Creek with Clifton Channel is designated critical habitat and provides rearing habitat for the same ESU/DPSs as the log pond that would be filled at the LNG terminal (see section 4.6.2.2). The Hunt Creek Mitigation Site would be a preservation area. The only active management proposed is the control of invasive weeds (e.g., purple loosestrife) to prevent a reduction of wetland and habitat functions.

The primary goal of the Hunt Creek Mitigation Site would be to assure protection and preservation of the tidal wetlands and stream habitat associated with the portion of Hunt Creek that would be located within the property owned by NorthernStar by placing a conservation easement on the title. Preservation of the Hunt Creek Mitigation Site would provide ongoing benefits to salmonids and other aquatic resources within the Columbia River estuary.

Monitoring and Adaptive Management

NorthernStar has committed to monitor fisheries at the Svensen Island Mitigation Sites semiannually for the first five years of the project. Following this period, monitoring would be conducted annually throughout the life of the project. Monitoring would include surveying and recording of the quality and extent of fisheries habitat present; taking depth measurements at various locations during both low and high tides to capture the extent of tidal function; observing fish directly to define patterns of access and utilization of the mitigation sites; and determining function of LWD. Due to proposed

activities at the Hunt Creek Mitigation Site being limited to noxious weed control, monitoring is not currently proposed.

The Svensen Island Mitigation Sites are considered new mitigation sites. Therefore, adaptive management would be needed. A number of corrections in management may be required to keep the mitigation site accessible to fish, grow appropriate vegetation, and maintain a properly functioning hydrologic regime. Working from the monitoring reports, management would be adjusted to ensure that mitigation objectives would be met despite obstacles that may occur.

4.5.2.2 Essential Fish Habitat

EFH is described in detail in section 4.5.1.2. Construction and operation of the proposed LNG terminal has the potential to impact one species of groundfish (starry flounder) and two species of Pacific coast salmon (Chinook and coho). These species are discussed below.

Of the 90 species managed by the groundfish FMP, only the starry flounder has been documented in freshwater habitat, such as at the proposed LNG terminal site. As described in section 4.5.1.2, starry flounder have been documented as residents in the lower Columbia River (Bottom and Jones, 1990). All life stages of the starry flounder are present in estuaries; however, only juveniles and adults occur in freshwater. Juvenile starry flounder prefer habitat with sandy to muddy substrates and adults prefer habitat with sandy to coarse substrates. Both of these substrate types occur at the proposed LNG terminal site, thus making it potential habitat for starry flounder. EFH for eggs, parr, smolt, and adult Chinook and coho salmon occur at the proposed LNG terminal site.

General project activities potentially impacting EFH include dredging of the berth and maneuvering area, filling of the log pond, shoreline development, pile driving, water withdrawals and discharges, railroad realignment, Hunt Creek Bridge replacement, and accidental spills or leaks of hazardous materials.

Potential impacts on aquatic resources (which include EFH) from construction of the proposed LNG terminal and maintenance dredging of the ship berth and maneuvering area are discussed in detail in section 4.5.2.1. As shown in table 4.5.2-1, dredging of the ship berth and maneuvering area, removal of riparian vegetation, shoreline development, pile driving, and water withdrawals and discharges would result in a substantial adverse effect on EFH for eggs, parr, smolt, and adult Chinook and coho salmon as well as juvenile and adult starry flounder. In addition, filling of the log pond and wetlands at the LNG terminal site, realignment of the railroad, and replacement of the Hunt Creek Bridge would result in substantial adverse impacts on Pacific coast salmon EFH. Construction adjacent to EFH could also result in increased stormwater runoff and/or an inadvertent spill of hazardous materials, either of which could result in substantial adverse effects on EFH. Construction and maintenance of the power line would result in impacts on the waterbodies crossed by the power line, which are unnamed tributaries to Hunt Creek. However, these tributaries are located upstream of Hunt Creek falls; therefore, because there is no fish passage above the falls and the tributaries are at least 5,700 feet from Hunt Creek falls and at least 2,500 feet from the Columbia River, impacts on EFH would not be expected to occur. A detailed discussion of measures that would be implemented to avoid or minimize impacts on aquatic resources (which include EFH) is presented in section 4.5.2.1.

TABLE 4.5.2-1			
Potential Impacts on EFH Due to the Bradwood Landing LNG Terminal			
EFH	Description of EFH	Project Action with Potential Impacts on EFH	Determination of Effect
Groundfish	Aquatic habitat from the extent of saltwater intrusion in river mouths to the boundary of the EEZ.	Accidental spill or leak of hazardous materials. Dredging of the berth and maneuvering area. Removal of riparian vegetation. Shoreline development. Pile driving. Water withdrawals and discharges.	Substantial adverse effect on starry flounder EFH (see section 4.5.2.1 for a discussion of mitigation measures).
Pacific Coast Salmon	All streams, lakes, ponds, wetlands, and other waterbodies currently and historically accessible to salmon.	Accidental spill or leak of hazardous materials. Dredging of the berth and maneuvering area. Removal of riparian vegetation. Shoreline development. Pile driving. Water withdrawals and discharges. Filling of the log pond. Railroad realignment. Hunt Creek Bridge replacement.	Substantial adverse effect on Pacific Coast salmon EFH (see section 4.5.2.1 for a discussion of mitigation measures).

4.5.2.3 Terrestrial Wildlife

As described in section 4.4.2.2, the Bradwood Landing LNG terminal site comprises eight distinct upland vegetation cover types. These vegetative communities provide nesting, cover, and/or foraging habitat for a variety of wildlife. Open water and wetland habitats also provide these functions for wildlife species. Potential impacts on these habitats are described and quantified in sections 4.3.2.3 and 4.4.1.2, respectively. The wildlife habitats that would be impacted by the proposed LNG terminal are shown in table 4.5.2-2.

TABLE 4.5.2-2		
Acreages of Wildlife Habitats Impacted by the Bradwood Landing LNG Terminal		
Habitat	LNG Terminal ^a	
	Construction	Operation
Coniferous forest	8.6	8.6
Deciduous forest	7.8	6.0
Early seral forest	8.6	5.6
Riparian forest	0.7	0.5
Scrub-shrub	12.8	2.2
Riparian scrub-shrub	<0.1	<0.1
Palustrine emergent wetland	5.7	5.7
Palustrine scrub-shrub wetland	3.4	2.7
Multiple wetland types	5.6	4.5
Open water	63.5	59.0
Dredged materials/bare ground	21.3	19.3
Developed and roads	5.1	2.0
Total	143.2	116.1
Note: The totals shown in this table may not equal the sum of addends due to rounding		
^a	The LNG terminal includes terminal facilities, Hunt Creek Bridge replacement, and power line.	
^b	Since the issuance of the draft EIS, modifications have been proposed to Clifton and Bradwood Roads and the construction worker parking area. Information quantifying these impacts on wildlife habitats has not been provided.	

Table 4.5.1-2 identifies some of the wildlife species that are common to these habitats. The most prevalent habitats are open water, forest (i.e., coniferous, deciduous, mixed, early seral, and riparian forests), and wetlands (i.e., palustrine emergent, scrub-shrub, and multiple wetland types). Open water habitats account for approximately 44.3 percent of the wildlife habitat affected. Impacts on wildlife occurring in open water habitats are discussed in section 4.5.2.1. As described in section 4.5.1.3, forest habitats provide the greatest vertical structure and support diverse faunal assemblages. Wetland habitats support diverse floral species and provide foraging and dispersal habitat for a wide variety of wildlife species. These habitats account for about 17.9 and 10.2 percent, respectively, of the wildlife habitat that would be affected by construction of the proposed LNG terminal. A portion of the forest and wetland habitats would also be considered riparian habitat. Similar to the other forest habitats, riparian forest provides significant vertical structure, and generally supports the most diverse faunal assemblages of the affected habitats. The least prominent habitats that would be affected are, in descending order of prevalence, dredged materials and bare ground (14.8 percent), upland scrub-shrub (8.9 percent), developed (3.6 percent), and riparian scrub-shrub (less than 0.1 percent).

General Impacts on Terrestrial Wildlife

The impact of the project on terrestrial wildlife species and their habitats would vary depending on the requirements of each species and the existing habitat present within the project area. Construction of the proposed LNG terminal would affect 143.2 acres of wildlife habitat, and would permanently convert approximately 32.1 acres of land to industrial use. Direct impacts of construction on wildlife would include the displacement of wildlife within the project area and direct mortality of some individuals. Potential impacts on terrestrial wildlife from construction and operation of the proposed LNG terminal are discussed below.

During construction activities, mobile wildlife, such as birds and larger mammals, would be expected to leave the vicinity of the project area. Noise associated with construction could also disrupt bird courting or nesting and breeding of other wildlife in the vicinity of the proposed project. Impacts on migratory birds and proposed minimization measures are described in section 4.6.2.2. Animals displaced by construction activities may relocate into similar habitats nearby; however, the lack of adequate territorial space could force some animals into suboptimal habitats. The influx and increased density of animals in some undisturbed areas caused by these dislocations could increase inter- and intra-specific competition and also reduce the reproductive success of animals that are not displaced by construction. The loss of these individuals could result in a decrease in the food stock available for predators of these species. Additionally, some smaller, less mobile wildlife, such as small mammals and burrowing species (e.g., mice, voles, weasels, and beaver), amphibians, and reptiles, could be crushed by construction equipment or trapped in trenches. However, these effects would cease after construction and wildlife would return to the newly disturbed areas and adjacent, undisturbed habitats after restoration is completed.

As discussed in table 4.5.2-2, about 25.7 acres of upland forested habitat would be affected by construction of the LNG terminal and associated power line. Forested habitats affected by the LNG terminal would include 8.6 acres of coniferous forest, 7.8 acres of deciduous forest, 8.6 acres of early seral forest, and 0.7 acres of riparian forest. The greatest impact would be on sensitive species such as the olive-sided flycatcher, bald eagle, and other species associated with remnant mature coniferous forests that might have used this habitat for nesting or other activities (see section 4.6.2.2). The loss of some trees in this already small patch of habitat would decrease the proportion of habitat that is insulated from the edge, thus making the habitat less attractive to some species.

The scrub-shrub habitat (12.8 acres) impacts would be shorter term than the impacts on forest lands, but regeneration of these areas could still take up to 3 years. Although the structural component of

scrub-shrub habitats would recover slowly, successful restoration of non-woody vegetation may improve the value of forage for some wildlife within a relatively short time.

A total of about 0.7 and 14.8 acres of riparian forest and wetland habitats, respectively, would be affected by construction of the LNG terminal. These areas are important habitats for a number of resident wildlife species. Disturbance to these habitats would be minimized through implementation of NorthernStar's terminal ESC Plan.

Substrate disturbance associated with dredging and LNG carrier transit, especially in nearshore areas of the Columbia River, may temporarily reduce the availability of prey for many bird species. However, impacts would be temporary, as use of these habitats would resume upon the completion of construction.

Impacts on wildlife and their habitats from construction and operation of the LNG terminal would be mitigated for in accordance with recommendations from the FWS, ODFW, and WDFW as described in NorthernStar's preliminary Compensatory Mitigation Plan, which is being developed in coordination with the FWS and the ODFW. Potential impacts on wildlife due to terminal lighting, terminal fencing, and the electric power line are discussed below.

Terminal Lighting

As discussed in section 4.5.2.1, construction of the LNG terminal would require the installation of temporary lighting to facilitate some construction activities and permanent operational lighting. Glare from terminal lighting can affect foraging, reproduction, communication, and other critical wildlife behaviors. In some cases, these behavioral changes can lead to alterations in population or community dynamics (e.g., changes to inter-specific competition and/or predation).

One of the most pervasive effects of night lighting is on behaviors controlling orientation (Wada et al., 1987; Witherington, 1997; and Evans and Ogden, 1996). Sometimes, artificial lighting may disorient organisms used to navigating in dark environments. For example, songbirds can confuse lights on buildings and communication towers for stars that provide navigational cues during migration. This disorientation can lead to birds striking buildings and towers or colliding with one another, especially under overcast or foggy weather conditions (Evans and Ogden, 1996; Evans and Rosenberg, 1999). Conversely, increased illumination may extend diurnal or crepuscular behaviors into the nighttime by improving an animal's ability to orient itself (Longcore and Rich, 2004). This can be beneficial to some individual animals by allowing them to extend the length of activities such as foraging or mating.

Behavioral changes associated with increased lighting can affect activity levels, foraging behavior, habitat use, and mating (Wolfe and Summerlin, 1989; Yurk and Trites, 2000; Bird et al., 2004). In a study conducted by Buchanan (1993), the ability of frogs to detect and consume prey was significantly reduced under increased lighting. Many frogs exhibit a narrow range of environmental illumination in which they are active; within this range, frogs exhibit certain behaviors (such as calling, breeding, and foraging) only at very specific light levels. Bird et al., (2004) found that mice used fewer patches of food and ate less in areas with artificial lighting, indicating that the perceived risk of predation increases with increased lighting (Lima and Dill, 1990). Alternatively, certain species of bats are attracted to and congregate around lit areas, presumably to feed on insects also attracted by the light (Blake et al., 1994; Rydell and Baagøe, 1996). Although outdoor lighting has been shown to affect flight, navigation, vision, migration, dispersal, oviposition, mating, feeding and has lead to increased predation in some moth species, many moth species appear unaffected by outdoor lighting (Frank, 1988). Large mammals, such as mountain lions, strongly avoid lit areas, which can alter their movement patterns and potentially increase habitat fragmentation (Longcore and Rich, 2004).

Artificial lighting could positively and negatively affect wildlife in the vicinity of the proposed LNG terminal. The specific impacts of artificial lighting on individual organisms, populations, or communities are difficult to predict. To minimize the positive and negative impacts of lighting on wildlife, the FWS has developed the *Service Interim Guidelines for Recommendations on Communications Tower Siting, Construction, Operation, and Decommissioning*. These guidelines, which NorthernStar has agreed to implement, can be applied to facilities other than communication towers and include recommendations to reduce the number and intensity of security lights to the minimum required and to use down-shielding lights. To avoid and minimize construction lighting effects during construction, lights would be shielded and directed as needed to illuminate the work areas and meet safety requirements, but to avoid extending off-site unnecessarily. Researchers speculate that in rural locations, down-shielding would have an even greater effect than in urban areas because there is less illumination from other lit structures (Reed et al., 1985). While potential project impacts from artificial lighting cannot be completely eliminated, implementation of the FWS's guidelines related to facility lighting would minimize the potential for terminal lighting to adversely affect wildlife in the project area.

Due to the presence of high-quality habitats that are frequently used by shorebirds, waterfowl, and other waterbirds migrating along the Pacific Flyway and the potential presence of sensitive wildlife species, additional measures are necessary to minimize impacts from terminal lighting on wildlife in the vicinity of the proposed project. Therefore, we have recommended in section 4.5.2.1 that NorthernStar continue to consult with the NMFS, FWS, ODFW, and other applicable agencies to finalize its Lighting Plan.

Terminal Fencing

Comments were received during the scoping process regarding the potential impacts of fencing on wildlife movement patterns. For security purposes, fencing would be constructed around the LNG terminal. The fencing that would surround the proposed LNG terminal would be 8-foot-high woven wire and topped with barbed wire, which would potentially change wildlife movement patterns. At this height, the fence would effectively preclude most if not all wildlife from jumping over the fence (Montana State University, Extension Service, 2000), thus minimizing or eliminating the risk of wildlife being trapped within the LNG terminal site. Measures to minimize impacts from fencing would include establishment and maintenance of passage for mammals and other terrestrial wildlife around the perimeter of the fenced LNG terminal. This would be accomplished by maintaining a natural grade and native vegetative community along the shoreline between the berm and the MLLW elevation as described in section 4.4.2.2. In addition, the majority of the fenced area (71.7 percent) would be graveled and developed for industrial use, and thus would not provide suitable habitat for foraging, breeding, dispersal, or other wildlife movements. Therefore, wildlife in the area would be expected to use other, more suitable areas of habitat for dispersal or other movements. As such, significant impacts on wildlife as a result of the installation of terminal fencing are not anticipated.

Power Line

Construction of the power line would temporarily impact about 17.7 acres of forested habitats. Following construction, 12.7 acres of forest habitats would be replanted with native trees and shrubs and allowed to revegetate. In general, temporary impacts on terrestrial wildlife due to construction of the power line would be similar to those described above for construction of the LNG terminal; however, impacts would be considered longer-term because of the time required to restore forest habitat to its preconstruction condition. The remaining 0.1 acre of habitat temporarily impacted by the power line would be upland scrub-shrub. Restoration of woody vegetation associated with upland scrub-shrub habitat would be complete within 3 to 5 years.

Impacts on wildlife from operation of the power line would be limited to disturbance during maintenance activities and potential electrocution of nesting birds. Maintenance activities would include mechanical and chemical control of about 5.0 acres of forested habitats within the power line right-of-way and maintenance of access roads, towers, and the transmission lines. These activities would be conducted by PacifiCorp and would be of limited duration, but would happen infrequently over the life of the power line. Activities would be conducted only as needed to prevent vegetation from interfering with operation and maintenance of the power line. For the most part, the affected vegetative communities would be early seral forest, which is often dominated by shrubby vegetation within the right-of-way (see section 4.4.2.2). However, some clearing and topping/limbing of coniferous forest could be required to accommodate the supporting towers.

Specific vegetation maintenance procedures that PacifiCorp would apply to maintenance of the power line include:

- mowing would be limited to 15 feet on either side of distribution primary wires and within power line rights-of-way;
- frequency of vegetative control using mechanical and chemical means would be determined based on need and annual inspections and would not occur on a predetermined basis;
- wetlands would be worked by hand in accordance with all applicable federal, state, and local laws and regulations;
- tree removal conditions are site- and tree-specific. However, tree clearing would generally be limited to within 15 feet of distribution conductors and within the 100-foot power line right-of-way. Removal of trees that are dead, dying, diseased, deformed, or unstable and that have a high probability of falling would be emphasized;
- trees would not be felled into streams in a way that could obstruct or impair the flow of water, unless instructed otherwise by the responsible governing agency. Machine work would not be performed within 50 feet of a live stream. Water pollution would be prevented and soil or debris would not be placed in streams. Equipment would use existing or designated stream crossings. State fish and wildlife agencies would be contacted if tree removal in and around streams could cause erosion or if resulting exposure could increase water temperature. Federal and state laws and regulations would be followed concerning stream protection; and
- pre-maintenance surveys would be conducted to protect migratory birds by marking active nests if the line must be worked during nesting season.

Comments were raised during the scoping process regarding the potential for the power line to electrocute migratory birds and nesting raptors during operation of the proposed project. To minimize impacts on birds, PacifiCorp has included specific elements in the power line and tower design for use in raptor areas. Additional discussion of potential impacts on migratory birds is included in section 4.6.2.2.

Unique or Sensitive Wildlife Habitats

Julia Butler Hansen National Wildlife Refuge

The proposed LNG terminal site is near the JBHNR, which is located on the far shore of the Columbia River in Washington and across Clifton Channel on Tenasillahe Island. The proposed ship berth and unloading facilities would be less than 2,000 feet from the closest point of the refuge – the southeast corner of Tenasillahe Island. The area historically has been used for the placement of dredged materials. As described above, the JBHNR contains over 5,600 acres of pasture, forested tidal swamp, woodlots, marshes, and sloughs along the Columbia River in both Washington and Oregon and supports a population of Columbian white-tailed deer federally listed as endangered under the ESA. The presence of potentially suitable Columbian white-tailed deer habitat within the LNG terminal site, as well as the site's proximity to the refuge suggests that this species may utilize the area. Potential impacts on the Columbian white-tailed deer and its habitat are discussed in section 4.6.2.2. Impacts on wildlife at the JBHNR as a result of construction and operation of the proposed LNG terminal would be limited to increased noise and terminal lighting. Impacts on wildlife as a result of terminal lighting are discussed above.

Increased noise would occur as a result of both construction and operation of the LNG terminal. As discussed in section 4.10.2.2, NorthernStar selected five (N1 - N5) noise measurement and analysis sites in the vicinity of the proposed LNG terminal (see figure 4.10.2-1). Although none of these sites were within the JBHNR, N2 and N3 (both located on Puget Island) are a similar distance from the proposed terminal site as the southeastern corner of Tenasillahe Island within the JBHNR across the Clifton Channel. Generally, the background noise levels at these locations are relatively low (46 to 48 A-weighted scale (dBA) L_{dn}). During dredging activities, noise levels are expected to average between 68 and 73 dBA L_{dn} at N2 and N3; during non-dredging construction activities at N2 and N3, noise levels would average between 50 and 53 dBA L_{dn} . During operation of the LNG terminal, the analysis showed an average increase of 4 dBA L_{dn} at N2 and N3. Noise levels attributed to construction and operation of the LNG facility drop off quickly to ambient levels at distances farther than N3 (farther than 1 mile from the LNG site). These data suggest that during construction and operation of the Bradwood Landing Project, noise levels at the southeastern corner of Tenasillahe Island would be higher than existing conditions. In fact, conditions may be noisy enough to disturb and/or displace some wildlife species found on the southeastern corner of Tenasillahe Island, particularly during dredging operations. However, this portion of the JBHNR is dominated by sands deposited during dredging of the Columbia River navigation channel, and is an area that provides limited value as wildlife habitat. As such, we anticipate only relatively minor impacts on wildlife inhabiting the JBHNR.

During the draft EIS comment period, comments were received regarding potential impacts on sensitive wildlife sites and sensitive species from blasting activities. NorthernStar would develop a Blasting Management Plan that would contain measures for noise mitigation. Due to the presence of both sensitive wildlife sites and high quality habitat for the Columbian white-tailed deer and other sensitive species in the vicinity of the LNG terminal, we recommend that:

- **NorthernStar should consult with the NMFS, FWS, ODFW, and other appropriate agencies in developing its Blasting Management Plan relative to the proposed noise mitigation measures. NorthernStar should file its Blasting Management Plan along with agency comments on the plan with the Secretary for review and written approval by the Director of OEP, prior to blasting activities.**

Oregon Major Big Game Habitat

The proposed LNG terminal site would be located within major big game habitat as mapped by Clatsop County. Elk and deer tracks were observed near the proposed terminal site during a site visit, and black bear have been observed at the site by previous property owners. The *Clatsop County Comprehensive Plan* (Clatsop County, 1996) includes development standards for ODFW-identified big game areas. To minimize disturbance to wildlife, NorthernStar would establish signage along roads and instruct project personnel to reduce vehicle speeds along roads where big game and Columbian white-tailed deer occur to avoid vehicle-animal collisions. Project personnel would also be instructed not to approach big game (either adults or young) at any time. Section 4.6.2.2 includes additional discussion of the Columbian white-tailed deer.

Active Osprey Nest

The proposed LNG terminal site currently supports an active osprey nest on an existing piling along the Columbia River shoreline near the southeast end of the LNG terminal site. Ospreys are common birds of prey that are frequently present near rivers and other waterbodies that provide sufficient quantities of aquatic prey. This species is common along the Columbia River and often builds nests on artificial nest platforms provided by the utility companies. These nest sites are frequently located in close proximity to roadways and other disturbed sites.

The osprey nest would be affected by increased noise and visual disturbance coming from the construction area, which could lead to nest abandonment and failed reproduction. Therefore, NorthernStar has consulted with biologists from the FWS and ODFW to identify appropriate measures to avoid or minimize disturbance to nesting osprey and avoid a “taking” under the Migratory Bird Treaty Act. Per ODFW recommendations, osprey nest relocation would be conducted outside of the critical nesting period (early September through late February). This relocation would occur when no osprey courtship behavior is observed at the site and when the nest is not being actively used (i.e., outside of the breeding season).

Osprey typically exhibit a high degree of nest fidelity and are likely to attempt to rebuild at the existing location unless a superior site is provided nearby. As such, the relocated structure would be of comparable or better quality and meet the following conditions:

- the new nest platform would be in an exposed location that is as high or higher than the original nest site and surrounding structures (including power lines);
- the new location would be located as close as possible to the existing nest, but no closer than 0.25 mile from activities associated with construction and operation of the LNG terminal;
- the new location would be no closer than 600 feet to an existing osprey, bald eagle, or peregrine falcon nest;
- if using a transmission pole, a predator guard (sheet metal) would be installed at the base of the pole;
- an elevated perch (minimum of 3 feet above the nest platform) would be included in the platform design to attract the osprey pair to the new nest site;

- the platform and structure would be mounted securely and capable of supporting a nest that may weigh 100 to 200 pounds; and
- the old nest would be kept intact (if possible) and relocated onto the new platform; however, if the nest cannot be kept intact, portions of the old nest would be used to construct the new nest.

If the piling for the original nest were to be left intact, it would be modified to discourage ospreys from rebuilding a nest at the same site. This would likely be accomplished by installing a triangular perch guard to prevent osprey from landing and rebuilding the replaced nest.

Mitigation Measures

Project design, construction, and operation plans have been modified to avoid or minimize impacts on terrestrial wildlife. These efforts would be ongoing during construction in order to capitalize on avoidance and minimization opportunities that cannot be predicted. However, both direct and indirect impacts on wildlife would result from construction and operation of the proposed LNG terminal. Mitigation measures discussed in this section are specifically for impacts on upland habitats. Mitigation measures proposed by NorthernStar for wetland and aquatic habitats would also benefit terrestrial wildlife, and are discussed in sections 4.4.1.2 and 4.5.2.1, respectively, and in NorthernStar's Compensatory Mitigation Plan.

The FERC received numerous comments stating that the mitigation proposed by NorthernStar does not adequately compensate for impacts associated with the project. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. To ensure that the mitigation proposed for the Bradwood Landing Project adequately compensates for project-related impacts, we have recommended that NorthernStar continue to consult with the appropriate natural resource agencies to finalize its Compensatory Mitigation Plan. The final Compensatory Mitigation Plan should be filed along with agency comments and applicable approvals with the Secretary prior to construction of the project.

The primary proposed mitigation site for impacts on wildlife habitat is at Peterson Point, which is located 6 miles west of Clatskanie, Oregon. The Peterson Point Mitigation Site currently provides habitat for a variety of wildlife species including Columbian white-tailed deer, beaver, bald eagle, northern harrier, red-tailed hawk, numerous species of waterfowl and songbirds, and a variety of reptiles and amphibians, including tree frogs. About 40 to 100 Columbian white-tailed deer from the Oregon lowlands subpopulation occasionally use the site. Additionally, there are two bald eagle nests within a 2-mile radius of the site; one is located about 1.0 mile north of the mitigation site on a slough bordering Whites Island and the other is located about 1.8 miles from the site on Whites Island. No other federally endangered or threatened species have been documented at the Peterson Point Mitigation Site.

NorthernStar proposes to restore about 114 acres of native forest and about 31 acres of riparian habitat. As described in section 4.5.3.3, the current owner has been working with Ducks Unlimited to enhance wildlife habitat values through a combination of activities including blocking drainage ditches, installing flow control structures, and clearing hybrid poplars. The result is a mosaic of hybrid poplar stands, emergent wetlands and pasture/grassland habitats. The proposed mitigation parcels are in strategic locations throughout the site and include 114 acres of hybrid poplars on relatively higher ground that is drier than many of the other areas at the site due, in part, to flow control structures and pump stations, which regulate the water levels in the sloughs and ditches. In addition, the mitigation site contains 31 acres along the Columbia River and Westport Slough that are currently providing high-quality riparian habitat. Mitigation at this site would include a combination of preservation and enhancement by planting understory and riparian vegetation (for Columbian white-tailed deer), controlling noxious weeds,

installing artificial nest structures (for purple martins, osprey, wood ducks, and bats), and installing brush piles to provide refugia for small mammals, herptofauna, and ground-nesting birds. The parcels restored on the Peterson Point Mitigation Site would be protected in perpetuity from development by accomplishing deed restrictions, memorandums of understanding, and control by a third party.

The primary goal of the Peterson Point Mitigation Site would be to enhance and protect potentially suitable habitat for the Columbian white-tailed deer (see section 4.6.2.2). However, by restoring 145 acres of forested habitat, a net benefit would be provided to a wide variety of terrestrial wildlife species by increasing the availability of potential habitat for breeding, foraging, and dispersal. NorthernStar proposes to conduct annual monitoring of the Peterson Point Mitigation Site for 5 years. Monitoring reports, which would be submitted to the ODFW and FWS, would include a detailed summary of conditions of each of the parcels. In addition to submitting monitoring results, recommendations would be made for maintenance of non-native weedy species and/or corrective actions necessary to meet the performance standards.

NorthernStar has also developed an SEI, which would be implemented throughout the life of the project. Although the primary goal of the SEI would be to ensure the recovery of salmon and the lower Columbia River ecosystem, the projects would also benefit terrestrial species. The SEI is described in detail in section 4.6.2.2.

4.5.2.4 Oregon Department of Fish and Wildlife - Habitat Mitigation Policy

The ODFW developed a HMP (OAR 635-415-0010) to further fish and wildlife management policies “through application of consistent goals and standards to mitigate impacts on fish and wildlife habitat caused by land and water development actions” (ODFW, 2006a). The policy includes a description of six qualitative habitat categories, which are based on relative importance to fish and wildlife. The rule establishes mitigation goals and corresponding implementation standards for each habitat category. These categories with their mitigation goals and implementation standards are summarized below.

- Habitat Category 1 is irreplaceable, essential habitat for a fish or wildlife species, population, or a unique assemblage of species and is limited on either a physiographic province or site-specific basis, depending on the individual species, population, or unique assemblage. The mitigation goal for Category 1 habitat is no loss of either habitat quantity or quality. The implementation standard recommends or requires avoidance of impacts through alternatives to the proposed development action; or no authorization of the proposed development action if impacts cannot be avoided.
- Habitat Category 2 is essential habitat for a fish or wildlife species, population, or unique assemblage of species and is limited either on a physiographic province or site-specific basis depending on the individual species, population, or unique assemblage. The mitigation goal, if impacts are unavoidable, is no net loss of either habitat quantity or quality and to provide a net benefit of habitat quantity or quality. The implementation standard recommends or requires avoidance of impacts through alternatives to the proposed development action; or mitigation of impacts, if unavoidable, through reliable in-kind, in-proximity habitat mitigation to achieve no net loss of either pre-development habitat quantity or quality. In addition, a net benefit of habitat quantity or quality must be provided. If this cannot be achieved, the ODFW shall recommend against or shall not authorize the proposed development action.

- Habitat Category 3 is essential habitat for fish and wildlife, or important habitat for fish and wildlife that is limited either on a physiographic province or site-specific basis, depending on the individual species or population. The mitigation goal is no net loss of either habitat quantity or quality. The implementation standard recommends or requires avoidance of impacts through alternatives to the proposed development action; or mitigation of impacts, if unavoidable, through reliable in-kind, in-proximity habitat mitigation to achieve no net loss in either pre-development habitat quantity or quality. If this cannot be achieved, ODFW shall recommend against or shall not authorize the proposed development action.
- Habitat Category 4 is important habitat for fish and wildlife species. The mitigation goal is no net loss in either existing habitat quantity or quality. The implementation standard recommends or requires avoidance of impacts through alternatives to the proposed development action; or mitigation of impacts, if unavoidable, through reliable in-kind or out-of-kind, in-proximity or off-proximity habitat mitigation to achieve no net loss in either pre-development habitat quantity or quality. If this cannot be achieved, ODFW shall recommend against or shall not authorize the proposed development action.
- Habitat Category 5 is habitat for fish and wildlife having high potential to become either essential or important habitat. The mitigation goal, if impacts are unavoidable, is to provide a net benefit in habitat quantity or quality. The implementation standard recommends or requires avoidance of impacts through alternatives to the proposed development action; or mitigation of impacts, if unavoidable, through actions that contribute to essential or important habitat. If this cannot be achieved, ODFW shall recommend against or shall not authorize the proposed development action.
- Habitat Category 6 is habitat that has low potential to become essential or important habitat for fish and wildlife. The mitigation goal is to minimize impacts. The implementation standard recommends or requires actions that minimize direct habitat loss and avoid impacts on off-site habitat.

NorthernStar's Compensatory Mitigation Plan identified a number of sites in the general project area that would be set aside and/or developed as compensatory mitigation. Specifically, these sites would compensate for temporary or permanent impacts on wetlands, wildlife habitats, and salmonid habitats that could not otherwise be mitigated. The compensatory mitigation sites were identified only after all other forms of impact mitigation (i.e., avoidance, minimization, rectification, and reduction) were considered and, when appropriate, implemented. In developing these sites, it is NorthernStar's intent to provide an overall net benefit to the environment of the lower Columbia River ecosystem. However, because NorthernStar's Compensatory Mitigation Plan has not been finalized, we recommended in section 4.4.1.1, that NorthernStar continue to consult with the COE, ODSL, WDE, other applicable agencies, and appropriate Native American tribes to finalize its Compensatory Mitigation Plan. Based on NorthernStar's proposed compensatory mitigation and our recommendation to continue to consult with appropriate agencies regarding compensatory mitigation, we anticipate that the goals and standards of ODFW's HMP would be met.

4.5.3 Pipeline Facilities

4.5.3.1 Aquatic Resources

Existing Aquatic Resources

Anadromous and freshwater fish occurring in the lower Columbia River and its tributaries are described in section 4.5.1.1.

Commercial and Recreational Fisheries

Commercial and recreational fisheries of the lower Columbia River and its tributaries are described in section 4.5.1.1.

Impacts on Aquatic Resources

General project activities potentially impacting aquatic resources include in-water construction activities, terrestrial/riparian habitat modification, water appropriations, accidental spills or leaks of hazardous materials, and periodic maintenance of the pipeline. Much of the impact discussion included below applies to the fish protected under the ESA, which are described in detail in sections 4.6.1.1 and 4.6.2.3, and to EFH designated under the MSA, which is discussed further in section 4.5.2.3.

In-Water Construction Activities

Fish and other aquatic resources could be impacted by in-water construction activities associated with pipeline construction. The degree of impacts on fish associated with construction activities would depend on the timing of in-water construction. Construction during periods of sensitive fish activity (i.e., spawning, juvenile rearing, and migration) can have a greater impact on fish than construction during other periods. To minimize impacts on fish, pipeline construction within waterbodies would occur during in-water work windows designated by the ODFW and WDFW.

The proposed pipeline would impact 94 waterbodies, of which 52 are intermittent and 42 are perennial. Of these, up to 23 would be crossed using the HDD or conventional bore methods, which would avoid in-water construction activities. The remaining waterbodies would be crossed using a dry open-cut method (see table 4.3.2-4). Waterbody crossing methods are described in detail in sections 2.4.2.2 and 4.3.2.4).

In-stream construction across waterbodies would directly affect aquatic resources. In addition, construction across waterbodies would remove vegetation and habitat, thereby potentially increasing the sedimentation and turbidity of the water, streambank erosion, and water temperature. Construction-related impacts on aquatic resources could also result from an inadvertent release of drilling mud during HDDs. A discussion of potential impacts on aquatic resources is provided below. The degree of impact would depend on the proposed crossing method, the existing conditions at each crossing location, the mitigation measures employed, and the timing of construction.

Dry waterbody crossing methods (i.e., diverted dry open-cut, flume, dam and pump) could interfere with essential life processes. In-stream construction could also delay or prevent migrating fish from reaching upstream spawning areas or could delay downstream movement of juveniles. Equipment moving through a stream and the trenching of a waterbody could physically damage fish, fish eggs, and other aquatic organisms, including fish prey and forage species. In-stream structures for support of equipment bridges over streams may similarly impact fish and other aquatic organisms. The HDD and

conventional bore methods avoid in-stream construction and generally minimize impacts on aquatic resources.

The majority of the waterbodies affected by the Bradwood Landing Project would be crossed using the dam and pump or flume method if water is flowing in the waterbody at the time of construction. In-stream activities associated with placing the flume pipe and constructing the sandbag dams would be expected to displace most fish either upstream or downstream from the dams. Flumes and dams would be completely installed and functioning before any in-stream disturbance. All flume and dam and pump crossings would be completed as a single effort to minimize the duration of in-stream disturbance.

Inadvertent Release of Drilling Mud

NorthernStar proposes to install the pipeline across all 12 waterbodies containing federally listed salmonids or their designated critical habitat (see table 4.3.2-6) using the HDD or conventional bore method. The HDD and bore methods eliminate the need to excavate a trench through the stream or river channel, and would minimize or eliminate sedimentation and turbidity associated with the more common open-cut methods of pipeline construction. NorthernStar has agreed to follow our Procedures, which require submittal of a plan prior to construction that contains site-specific diagrams showing the location of mud pits, pipe staging areas, and all areas to be disturbed or cleared for construction.

Although the HDD method would minimize or avoid in-stream impacts on aquatic resources because it eliminates the need for in-stream excavation, it does not completely eliminate the possibility of impacts due to the possibility of an inadvertent release of drilling mud or fluid (also referred to as a frac-out) into the waterbody. Drilling mud primarily consists of water mixed with bentonite, which is a naturally occurring clay material. The only other possible additives would be non-toxic solid materials (e.g., sawdust, nut shells, bentonite pellets, or other commercially available non-toxic products) that could be needed to plug an inadvertent release. Bentonite, by itself, is essentially non-toxic (Breteler et al., 1985; Hartman and Martin, 1984; Sprague and Logan, 1979). However, bentonite, as with any fine particulate material, can interfere with oxygen exchange by the gills of aquatic organisms (EPA, 1986). The degree of interference generally increases with water temperature (Horkel and Pearson, 1976). Impacts would be localized and would normally be limited to individual fish in the immediate vicinity of the frac-out. The majority of highly mobile aquatic organisms, such as fish, would be able to avoid or move away from the affected area. Other less mobile or immobile organisms, such as fish eggs, mussels, and other macroinvertebrates, would incur direct mortality.

Comments were received on the draft EIS relating to potential impacts on spawning habitat due to a frac-out during pipeline construction. As stated above, if fish eggs are present in the vicinity of a frac-out, direct mortality could occur. However, at the time of a frac-out, NorthernStar would stop drilling immediately and notify appropriate agencies. A vacuum truck or pump(s), with a sufficient hose, would then be used to remove the bentonite, working from downstream to upstream, to allow maximum visibility. Hand tools may be used to scarify the sediments and ensure removal to the maximum extent practicable, thus minimizing impacts on spawning habitat.

As discussed in section 4.3.2.4, the highest potential for a frac-out typically occurs at the beginning or the end of the HDD borehole where the separation between the borehole and ground surface is the least. NorthernStar has designed the proposed HDD crossings so that areas at greatest risk of a potential inadvertent release are in upland areas away from the water's edge. HDD entry and exit pits would be located a minimum of 75 feet from sensitive waterbodies (Appendix B), which would minimize the potential for an inadvertent release into a waterbody, thereby minimizing the likelihood of impacts on aquatic resources. NorthernStar's *HDD Contingency Plan* describes how the drilling operations would be conducted and monitored to minimize the potential for inadvertent drilling mud releases. The plan also

includes procedures and measures to be taken during an inadvertent release of drilling mud. NorthernStar would station the necessary equipment and supplies to respond to an inadvertent release of drilling mud upon discovery of loss of drilling fluid. At the time of a release of drilling mud, NorthernStar would stop drilling immediately, contain drilling fluids, and notify appropriate agencies. Appropriate resource experts, such as fisheries biologists and wetland scientists would be brought onsite to monitor resources and effects of the release.

Suspended Sediments and Turbidity

Increased suspended sediment and turbidity levels, due to in-water trenching and backfilling, would pose the greatest potential for impacts on aquatic species due to construction of the proposed pipeline. The extent of the impact would be dependent on sediment loads, water velocity, and sediment particle size at the time of construction. Potential impacts of clearing the pipeline right-of-way would be analogous to, but on a much smaller scale than, timber harvest and associated road construction, which have been found to increase the frequency and magnitude of soil destabilization, erosion, and eventually stream sedimentation (Everest et al., 1987; Swanson et al., 1987). As discussed above, sedimentation can adversely affect fish eggs and fish survival, benthic community diversity and health, and spawning habitat. Suspended particles and sediment can result in turbidity in sufficient quantities to affect oxygen exchange over the gills in aquatic species, resulting in weakened individuals or mortality. Additionally, sediment stirred into the water column can be redeposited on downstream substrates, which could bury aquatic macroinvertebrates (an important food source for salmonids). However, studies indicate that impacts on streams and rivers from typical pipeline construction would be temporary, and that no long-term effects on water temperature, pH, dissolved oxygen, benthic invertebrate populations, or fish populations would occur (Vinkour and Shubert, 1987; Blais and Simpson, 1997). To reduce sedimentation and erosion, NorthernStar would perform turbidity monitoring in accordance with state permits, implement its pipeline ESC Plan for Oregon, and its SWPPP for Washington. NorthernStar would compensate for impacts on surface waters and aquatic resources that could not be avoided by setting aside or developing a number of mitigation sites, which are described in its Compensatory Mitigation Plan.

Vegetation and Habitat Removal

Aquatic resources could be affected through the removal of vegetation and habitat at the waterbody crossing sites. Potential impacts include increased water temperature, decreased LWD and the associated reduction in habitat, and increased mass failures adjacent to waterbodies. These impacts are discussed below.

Clearing the right-of-way would remove shading vegetation from uplands and riparian areas, exposing the land and water to increased sunlight, resulting in both direct increases in water temperatures and indirect increases as water flows over the warmer land surface and eventually reaches the waterbody (Beschta and Taylor, 1988). The effects of water temperature on the life stages of salmonids have been extensively reviewed and are described in section 4.5.2.1. To mitigate these potential impacts, NorthernStar would allow a corridor at least 25 feet wide, as measured from the OHWM, to permanently revegetate with native plant species across the entire construction right-of-way following construction. However, to facilitate access for periodic pipeline corrosion/leak surveys, a corridor centered on the pipeline and up to 10 feet wide may be maintained in an herbaceous state. NorthernStar's use of the HDD construction method to cross waterbodies would also limit impacts on riparian habitats. The only potential disturbance in riparian areas crossed using the HDD method would be minor trimming of vegetation using hand tools directly over the pipeline. This minor clearing is required to facilitate the temporary deployment of HDD guidance (telemetry) cables along the ground during construction and to perform a leakage survey after installation and commissioning.

In addition to potential temperature impacts, one of the most significant potential effects of forest clearing on fisheries is the reduction of LWD in streams and on land (Harmon et al., 1986; Sedell et al., 1988). Large logs provide in-stream channel structures (i.e., pools and riffles), which are critical to salmon spawning and rearing. As the size of individual logs or accumulations of logs increases, the size and stability of pools that are created also increase (Beschta, 1983). Riparian forests that undergo harvesting of large trees take on secondary-growth characteristics and contribute lower quantities of woody debris than unmanaged, old-growth forests (Bisson et al., 1987). However, sufficiently wide, carefully managed riparian buffers that retain a full complement of ages, sizes, and species of native trees and vegetation can ensure adequate recruitment of LWD to streams (Bisson et al., 1987; Murphy and Koski, 1989; Morman, 1993).

NorthernStar is consulting with the FWS, NMFS, and state agencies regarding potential mitigation for replacement of in-stream habitat. These preliminary discussions indicate that mitigation could include the placement of LWD within the waterbodies following construction to mitigate for loss of habitat from in-stream construction. The use of LWD as a mitigation measure for impacts associated with in-stream construction has been documented as an effective means of creating in-stream habitat heterogeneity, reducing streambank erosion, reducing sediment mobilization, and enhancing local fish abundance (Scarborough and Robertson, 2002; Bethel and Neal, 2003). Because short-term loss of riparian vegetation within construction work areas may affect water temperatures by removing shade sources, placement of LWD on the streambanks and in the streams can provide shade and increase bank stability while vegetation is maturing following construction. Additionally, placement of LWD in streams or on streambanks can supply habitat for forage species and enhance the salmonid rearing potential of an area. Due to the importance of numerous fish species in waterbodies along the proposed route, we have recommended in section 4.3.2.4 that NorthernStar continue to consult with the COE, NMFS, FWS, and appropriate federal and state agencies to finalize its *Waterbody and Wetland Construction and Mitigation Procedures Plan*, including a description of the specific methods of in-water habitat mitigation to be conducted.

Forest clearing and construction have also been found to increase the frequency and amount of sediment production through mass failures which are a major contributor of sediment to streams, particularly in steep landscapes (Swanson et al., 1987). Mass failures adjacent to streams and resulting debris flows carve stream banks, thereby resulting in significant patches of bare ground. These areas favor revegetation by fast-growing species such as red alder rather than a diverse plant community which is normally characteristic of riparian habitats (Knutson and Naef, 1997). Debris flows also move LWD to floodplain areas or to concentrated locations, reducing the distribution of this habitat throughout the stream (Swanson et al., 1987). Although the potential for mass failures cannot be completely eliminated, since this is also a natural phenomenon, NorthernStar would ensure equipment stability and worker safety by avoiding the placement of HDD or bore entry and exit pits in areas where steep slopes are present because they require significant extra workspace as compared to open-cut methods. Clearing this extra workspace on already unstable sideslopes would increase the likelihood of mass failures and landslides. NorthernStar would also implement its pipeline ESC Plan for Oregon and its SWPPP for Washington to reduce the potential for mass failures. In addition, we have also recommended that NorthernStar conduct additional field mapping and subsurface investigations as needed to develop a Final Pipeline Design Geotechnical Report.

Streambank Erosion

The clearing and grading of vegetation during construction could increase erosion along streambanks and turbidity levels in the waterbodies. Alteration of the natural drainage ways or compaction of soils by heavy equipment near streambanks during construction may accelerate erosion of the banks, runoff, and the transportation of sediments into waterbodies. The degree of impact on aquatic

organisms would depend on sediment loads, stream velocity, turbulence, streambank composition, and sediment particle size. To minimize these impacts, NorthernStar would use temporary equipment bridges, mats, and pads to support equipment that must cross the waterbody or work in saturated soils adjacent to the waterbody. In accordance with our Procedures and where topography allows, NorthernStar would attempt to preserve a minimum of 10 feet of vegetation along the waterbody banks during clearing and grading and locate temporary extra workspaces back from the edge of perennial and intermittent waterbodies where feasible to minimize the disturbance of riparian vegetation. As discussed in section 4.4.2.3, NorthernStar would allow a corridor at least 25 feet wide, as measured from the OHWM, to permanently revegetate with native plant species across the entire construction right-of-way following construction. At waterbodies that would be crossed via the HDD method, the only anticipated streambank disturbance would be minor trimming of vegetation using hand tools directly over the pipeline. NorthernStar would also install sediment barriers, such as silt fence and straw/hay bales, adjacent to waterbodies until the right-of-way revegetation is complete.

Introduction of Exotic Species

Comments were received on the draft EIS stating that invasive mussels may occur within waterbodies crossed by the proposed project. Although NorthernStar has developed a *Noxious Weeds and Soil-borne Plant Disease Control Plan* for upland vegetation, a similar plan has not been developed to prevent the introduction of invasive species into waterbodies impacted by pipeline construction. Therefore, we have recommended in section 4.3.2.4 that NorthernStar continue to consult with the COE, NMFS, FWS, and appropriate federal and state agencies to finalize its *Waterbody and Wetland Construction and Mitigation Procedures Plan*, including measures to prevent the spread of invasive species due to construction activities within waterbodies.

Terrestrial/Riparian Habitat Modification

Fish and other aquatic resources could be impacted indirectly by activities that alter terrestrial and riparian habitat including upland pipeline construction. The clearing and grading of vegetation during construction could increase erosion along streambanks and turbidity levels in the waterbodies. Alteration of the natural drainage ways or compaction of soils by heavy equipment near streambanks during construction may accelerate erosion of the banks, runoff, and the transportation of sediments into waterbodies. The degree of impact on aquatic organisms due to erosion would depend on sediment loads, stream velocity, turbulence, streambank composition, and sediment particle size. Potential impacts due to vegetation clearing are discussed above (see *Vegetation and Habitat Removal*). NorthernStar would minimize potential impacts on wildlife during construction by implementing the procedures in its pipeline ESC Plan for Oregon and SWPPP for Washington. To avoid impacts on aquatic habitat during operation of the project, NorthernStar would allow a riparian strip at least 25 feet wide, as measured from the waterbody's MHW mark, to permanently revegetate with native plant species across the entire construction right-of-way. Within the riparian strip, trees greater than 15 feet tall, or deep-rooted shrubs that could damage the pipeline's protective coating, obscure periodic surveillance, or interfere with potential repairs, would not be allowed to grow within 15 feet (30 feet total) of the pipeline (see section 4.4.2.3).

Water Appropriation

As discussed in section 4.3.2.4, NorthernStar would appropriate water from the Columbia River for hydrostatic testing of the proposed pipeline. As described in section 4.5.2.1, NorthernStar would obtain the necessary permits from state agencies before withdrawing water and use modern fish screening technology on surface water intakes. The volume of water withdrawn for hydrostatic testing of the pipeline would not measurably reduce downstream flows. Water appropriated for hydrostatic testing of

the pipeline would be discharged to an upland area near the pipeline crossing of the Columbia River using appropriate filtering techniques. The water would be discharged at an approximate rate of 1,000 gpm and would not be chemically treated. All discharges would be in compliance with NorthernStar's ODEQ water discharge permit and would not be expected to impact fish.

Accidental Spills or Leaks of Hazardous Materials

For any large construction project, there is the potential for spills or leaks of fuels or hazardous materials from storage containers, equipment working in or near streams, and fuel transfers. Any spill of fuel or hazardous liquid that reaches a waterbody would be detrimental to water quality. The chemicals released during spills could have acute, direct effects on fish, or could have indirect effects such as altered behavior, changes in physiological processes, or changes in food sources. Fish could also be killed if a large volume of fuel or hazardous liquid is spilled into a waterbody. Ingestion of large numbers of contaminated fish could affect primary and secondary fish predators in the food chain.

To minimize the potential for spills, NorthernStar prepared a pipeline ESC Plan and a SWPPP that include spill prevention and response procedures. NorthernStar's implementation of these plans would minimize the potential for and the impact of any spill near surface waters. Specific measures in these plans include prohibiting liquid transfer, vehicle and equipment washing, and refueling within 100 feet of waterbodies and specific steps to be followed to control, contain, and clean up any spill that occurs. NorthernStar's implementation of these plans would minimize the potential for and the impact of any spill near surface water during construction of the pipeline.

Crossing of Unstable Slopes

Most of the unstable slopes near sensitive waterbodies would be crossed by the HDD construction method. There are no other locations where the pipeline would cross an unstable slope within 200 feet upslope of a waterbody. Further information regarding unstable slopes and mitigation measures is provided in section 4.1.4.3.

Mitigation Measures

Project design, construction, and operation plans have been modified to avoid or minimize impacts on aquatic resources. These efforts would be ongoing during construction in order to capitalize on avoidance and minimization opportunities that cannot be predicted. However, both direct and indirect impacts on aquatic resources would result from construction and operation of the proposed pipeline. NorthernStar has committed to provide an overall net benefit to the environment of the lower Columbia River ecosystem.

Following construction of the pipeline, habitat and ecosystem function would be restored in place. Permanent impacts on aquatic resources would be mitigated by restoring habitat with similar ecological function. Mitigation would occur in areas substantially larger than that lost to permanent impacts, and would be restored to a higher level of ecosystem function. However, although compensatory mitigation actions would restore habitat and have long-term benefits to wetlands, estuarine ecosystems, and habitat for salmonids in general, there would be short-term adverse effects and longer term adverse effects on some non-target species. In terms of overall ecosystem health, these trade-offs are considered appropriate and valuable enough to more than balance the cost of the adverse effects.

As described in sections 4.5.2.2 and 4.5.2.3, NorthernStar identified a number of sites in the general project area that would be set aside and/or developed as compensatory mitigation in Oregon. In addition to these sites in Oregon, the Delameter Creek Mitigation Site would include restoration of

riparian habitats in Washington, thereby providing additional benefits to aquatic resources. This mitigation site is discussed in section 4.4.1.3.

The FERC received numerous comments stating that the mitigation proposed by NorthernStar does not adequately compensate for impacts associated with the project. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. To ensure that the mitigation proposed for the Bradwood Landing Project adequately compensates for project-related impacts, we have recommended that NorthernStar continue to consult with the appropriate natural resource agencies to finalize its Compensatory Mitigation Plan. The final Compensatory Mitigation Plan should be filed along with agency comments and applicable approvals with the Secretary prior to construction of the project.

4.5.3.2 Essential Fish Habitat

EFH is described in detail in section 4.5.1.2. Table 4.5.3-1 provides a list of the waterbodies impacted by the proposed route that provide EFH for salmonid species. For the purposes of this analysis, all fish-bearing streams that would be crossed by the proposed pipeline route are assumed to provide EFH for Chinook or coho salmon. Within the nine waterbodies designated as EFH for Chinook and/or coho salmon that would be crossed using the open-cut method, in-water work would affect a total of 0.4 acre of EFH would be temporary affected. As described in section 4.3.2.4, all waterbody crossings that involve open trenching would be constructed during established in-water work windows. To reduce impacts on EFH, NorthernStar would implement its *Waterbody and Wetland Construction and Mitigation Procedures Plan*, pipeline ESC in Oregon, and SWPPP in Washington as well as our Procedures.

In freshwater, EFH for Chinook and coho salmon include habitats for spawning, rearing, and migration corridors (PFMC, 2003). Components of the proposed pipeline with the potential to adversely affect designated EFH include removal of terrestrial and riparian vegetation, in-water pipeline construction, accidental spills and leaks of hazardous materials, and water appropriation for hydrostatic testing. Construction adjacent to EFH could also result in increased stormwater runoff and/or an inadvertent spill of hazardous materials, either of which could result in substantial adverse effects on EFH. Potential impacts on aquatic resources (which include EFH) from pipeline construction as well as measures that would be implemented to avoid or minimize impacts on aquatic resources is presented in section 4.5.3.1.

The determinations of effect on EFH resulting from the proposed Bradwood Landing pipeline are described in table 4.5.3-2. The FERC will respond to any EFH Conservation Recommendations issued by the NMFS through the EFH/ESA consultation process. Official written correspondence between FERC and the NMFS for the Bradwood Landing Project is part of the public record for this proceeding and is available through the FERC's internet web page (at www.ferc.gov) by clicking on the elibrary link.

4.5.3.3 Terrestrial Wildlife

As described in section 4.4.2.3, the Bradwood Landing pipeline would cross nine distinct upland vegetation cover types. Each of these vegetative communities provides nesting, cover, and/or foraging habitat for a variety of wildlife. Open water and wetlands habitats also provide these functions for wildlife species. Potential impacts on these habitat types are described and quantified in sections 4.3.2.4 and 4.4.1.3, respectively. Wildlife habitats crossed by the pipeline are shown in table 4.5.3-3.

Developed and roads	42.7	8.5
Total	437.6	126.0
^a Pipeline facilities includes the construction or permanent right-of-way, extra work spaces, and associated aboveground facilities.		

Table 4.5.3-4 identifies some of the wildlife species that are common to these habitats. The most prevalent habitats are forest (i.e., evergreen, deciduous, mixed, early seral, and riparian forests) and wetlands (i.e., palustrine emergent, scrub-shrub, forested, and multiple wetland types). Forest habitats provide the greatest vertical structure and support diverse faunal assemblages. Wetland habitats support diverse floral species and provide foraging and dispersal habitat for a wide variety of wildlife species. These habitats account for about 41.1 and 22.4 percent, respectively, of the wildlife habitat that would be affected by construction of the proposed project. A portion of the forest and wetland habitats would also be considered riparian habitat. Similar to the other forest habitats, riparian forest provides significant vertical structure, and generally supports the most diverse faunal assemblages of the affected habitats. Agricultural and developed lands account for approximately 22.5 and 9.8 percent, respectively, of the wildlife habitat affected. Although agricultural habitats support several cover types, they often have low diversity within each cover type. The least prominent habitats that would be affected are, in descending order of prevalence, open water habitats (2.5 percent), upland scrub-shrub (1.6 percent) and dredged materials and bare ground (<1.0 percent).

General Impacts on Terrestrial Wildlife

Construction of the proposed pipeline would affect 437.6 acres of wildlife habitat and would convert approximately 159.1 acres of land to permanent right-of-way, which would be maintained in an herbaceous state. The impacts of construction and operation of the proposed pipeline on terrestrial wildlife and wildlife habitats would vary depending upon the timing of construction and types of construction techniques used, as well as on the requirements of each species and the habitat present where various project components would be constructed. Direct impacts of construction on wildlife would include the displacement of wildlife within the project area and direct mortality of some individuals. In general, impacts on terrestrial wildlife due to construction of the pipeline and proposed mitigation measures would be similar to those described above for construction of the LNG terminal.

TABLE 4.5.3-4

Wildlife Species Occurring within the Vegetative Communities in the Bradwood Landing Pipeline Area

Vegetative Communities	Typical Wildlife Found within the Vegetative Communities
Forest ^a	<p>Amphibians: northwestern salamander, western red-backed salamander, roughskinned newt, western toad, Pacific treefrog, red-legged frog, bullfrog ^d.</p> <p>Reptiles: rubber boa, common garter snake, northwestern garter snake.</p> <p>Mammals: beaver, big brown bat, black bear, black-tailed deer, bobcat, bushy-tailed woodrat, California myotis, Columbian white-tailed deer, cougar, coyote, deer mouse, Douglas squirrel, elk, forest deer mouse, hoary bat, little brown myotis, long-eared myotis, long-legged myotis, mink, mountain beaver, porcupine, raccoon, red fox, silver-haired bat, striped skunk, Townsend's chipmunk, vagrant shrew, western gray squirrel, Yuma myotis.</p> <p>Birds: American robin, bald eagle, barred owl, belted kingfisher, blue grouse, black-capped chickadee, dark-eyed junco, downy woodpecker, great blue heron, great-horned owl, hairy woodpecker, northern flicker, olive-sided flycatcher, osprey, peregrine falcon, red-breasted nuthatch, red-tailed hawk, ruby-crowned kinglet, ruffed grouse, rufous hummingbird, song sparrow, spotted towhee, Steller's jay, Swainson's thrush, willow flycatcher, winter wren, and yellow-rumped warbler.</p>
Scrub-Shrub ^b	<p>Amphibians: Pacific treefrog, red-legged frog, bullfrog ^d.</p> <p>Reptiles: rubber boa, northwestern garter snake, common garter snake.</p> <p>Mammals: beaver, big brown bat, black-tailed deer, California myotis, Columbian white-tailed deer, coyote, deer mouse, hoary bat, little brown myotis, long-eared myotis, long-legged myotis, mink, nutria ^d, raccoon, red fox, Townsend's vole, Yuma myotis.</p> <p>Birds: American kestrel, American robin, Bewick's wren, dark-eyed junco, great blue heron, marsh wren, song sparrow, red-winged blackbird, red-tailed hawk, rufous hummingbird, white-crowned sparrow, wood duck.</p>
Wetlands ^c	<p>Amphibians: northwestern salamander, western toad, Pacific tree frog, red-legged frog, bullfrog ^d, Oregon spotted frog.</p> <p>Reptiles: western painted turtle, northwestern pond turtle, common garter snake.</p> <p>Mammals: beaver, big brown bat, black bear, California myotis, coyote, hoary bat, little brown myotis, long-eared myotis, long-legged myotis, mink, muskrat, northern river otter, nutria ^d, raccoon, striped skunk, silver-haired bat, Townsend's big-eared bat, vagrant shrew, Yuma myotis.</p> <p>Birds: American coot, belted kingfisher, Bewick's wren, black-bellied plover, black-capped chickadee, Canada goose, cinnamon teal, cliff swallow, common snipe, dunlin, great blue heron, greater yellowlegs, mallard, marsh wren, northern harrier, northern pintail, northern shoveler, peregrine falcon, pied-billed grebe, purple finch, red-winged blackbird, short-billed dowitchers song sparrow, sora, tree swallow, violet-green swallow, Virginia rail, western sandpiper.</p>
Streams and Ponds	<p>Amphibians: long-toed salamander, northwestern salamander, Pacific giant salamander, western toad, Pacific tree frog, red-legged frog, bullfrog ^d, Oregon spotted frog, tailed frog.</p> <p>Reptiles: western painted turtle, northwestern pond turtle, common garter snake, rubber boa.</p> <p>Mammals: beaver, big brown bat, black bear, California myotis, coyote, hoary bat, little brown myotis, long-eared myotis, mink, muskrat, nutria ^d, raccoon, silver-haired bat, Townsend's big-eared bat, Yuma myotis.</p> <p>Birds: American dipper, band-tailed pigeon, barn swallow, belted kingfisher, Bewick's wren, black swift, black-capped chickadee, black-throated gray warbler, Bullock's oriole, common merganser, common yellowthroat, great blue heron, green heron, hooded merganser, mallard, mourning dove, olive-sided flycatcher, peregrine falcon, red-eyed vireo, ruffed grouse, rufous hummingbird, song sparrow, spotted sandpiper, spotted towhee, warbling vireo, willow/alder flycatcher, Wilson's warbler, wood duck, yellow-breasted chat, yellow warbler.</p>
Nearshore	<p>Mammals: beaver, big brown bat, black bear, California myotis, Pacific harbor seal, hoary bat, little brown myotis, long-eared myotis, long-legged myotis, mink, muskrat, northern river otter, nutria ^d, raccoon, silver-haired bat, Steller sea lion, Townsend's big-eared bat, Yuma myotis.</p> <p>Birds: American dipper, bald eagle, bufflehead, California gull, Canada goose, Caspian tern, common goldeneye, cormorants, great blue heron, greater scaup, lesser scaup, mallard, northern rough-winged swallow, osprey, peregrine falcon, purple martin, red-winged blackbird, ring-billed gull, rock dove ^d, western grebe.</p>
Agricultural	<p>Mammals: beaver, big brown bat, black-tailed deer, black rat, California myotis, coast mole, coyote, creeping vole, deer mouse, fox squirrel, hoary bat, house mouse, little brown myotis, long-eared myotis, long-legged myotis, long-tailed vole, muskrat, shrew-mole, silver-haired bat, snowshoe hare, striped skunk, Townsend's big-eared bat, Townsend's mole, Townsend's vole, Trowbridge's shrew, vagrant shrew, Yuma myotis.</p> <p>Birds: American bittern, American crow, Canada goose, common yellowthroat, barn swallow, Brewer's blackbird, common snipe, house finch, house sparrow ^d, killdeer, mourning dove, northern harrier, red-tailed hawk, ring-necked pheasant, rock dove ^d, Savannah sparrow, song sparrow, spotted towhee, western meadowlark.</p>
Dredged Materials and Bare Ground	<p>Reptiles: common garter snake, northwestern garter snake.</p> <p>Mammals: black-tailed deer, deer mouse, raccoon.</p> <p>Birds: American Crow, killdeer, mourning dove, rock dove ^d, song sparrow, spotted towhee.</p>

^a Forested communities include coniferous, deciduous, mixed, early seral, and riparian forests.

^b Scrub-shrub communities include both upland scrub-shrub and riparian scrub-shrub.

^c Wetland communities include palustrine emergent, palustrine scrub-shrub, palustrine forested, and multiple wetland types.

^d Non-native species or invasive species occurring in the vicinity of the pipeline.

As described in detail in NorthernStar's pipeline ESC Plan, the entire construction right-of-way would be allowed to revegetate; however, large brush and trees would be periodically removed near the pipeline. Trees greater than 15 feet tall, or deep-rooted shrubs that could damage the pipeline's protective coating, obscure periodic surveillance, or interfere with potential repairs, would not be allowed to grow within 15 feet (30 feet total) of the pipeline. A 10-foot-wide area centered over the pipeline may be cleared annually, which would result in the conversion of forested communities to a grassland/herbaceous cover type.

Because much of the area affected by pipeline construction would be allowed to revert to the preconstruction habitat type, impacts on wildlife species would generally be short term. However, long-term impacts on terrestrial wildlife would occur in forested areas due to the time required to restore the forested habitat to its preconstruction condition. As discussed in section 4.4.2.2, about 176.8 acres of upland forested habitat would be affected by construction of pipeline facilities. Forested habitats affected by pipeline construction would include 76.2 acres of coniferous forest, 52.2 acres of mixed forest, 32.1 acres of deciduous forest, and 16.3 acres of early seral forest. Upland forested communities would be replanted in-kind with trees, with the exception of the portion of the right-of-way within 15 feet of the pipeline (30 feet total), resulting in permanent impacts on about 54 acres of upland forested communities.

Clearing of forested habitats associated with pipeline construction and maintenance would increase the amount of edge habitat in the area. Forest fragmentation can have negative effects on forest dwelling species, causing individuals to crowd into remaining patches of habitat. This can lead to increased competition for nesting habitat, breeding habitat, and food resources (Piatt et al, 2006). It also allows fringe forest species to move into the area, which can lead to competition for resources and can increase levels of predation and nest parasitism (Cornell Lab of Ornithology, 2003). Consequently, some studies have shown a positive correlation between nest success rates and greater distances from the forest edge (Piatt et al, 2006). However, due to the similar and ample habitat in the vicinity of the project, the conversion of 54 acres of forested habitats to herbaceous/grassland habitats would not be expected to have an adverse impact on wildlife populations.

Temporary impacts on scrub-shrub habitat due to construction (6.9 acres) of the pipeline would be more short term than the impacts on forest lands, but regeneration of these areas could still take up to 3 years. Although the structural component of scrub-shrub habitats would recover slowly, successful restoration of non-woody vegetation may improve the value of forage for some wildlife within a relatively short time.

A total of about 2.9 and 97.9 acres of riparian forest and wetland habitats, respectively, would be affected by construction of the pipeline facilities. These areas are important habitats for a number of resident wildlife species. Disturbance to these habitats would be minimized through implementation of NorthernStar's pipeline ESC Plan in Oregon and SWPPP in Washington and would be mitigated in accordance with recommendations from the FWS, NMFS, ODFW, and WDFW as described in NorthernStar's Compensatory Mitigation Plan. We have also recommended that NorthernStar consult with the appropriate federal and state resource agencies to develop a project specific Wetland Restoration Plan that would include measures to re-establish herbaceous and/or woody species, control exotic species, and monitor the success of wetland revegetation and weed control efforts. Additional discussion of wetland impacts and mitigation can be found in section 4.4.1.3.

Following construction and restoration, NorthernStar would monitor the revegetation of the right-of-way in non-cultivated areas during the first and second year after construction, and until revegetation is considered successful. Non-cultivated areas where seedling establishment has failed would be reseeded during the next appropriate seeding period. The revegetation of the construction area would be considered successful when, based on visual observation, the density or cover of well established,

herbaceous, non-nuisance vegetation in the construction area is similar to the density or cover of herbaceous vegetation in adjacent areas not disturbed by construction. If the herbaceous vegetative cover or density in the construction area is not similar to the herbaceous vegetative cover or density in adjacent areas not disturbed by construction, or if there are excessive noxious weeds after the first or second growing season, an agronomist would determine the need for additional restoration measures. NorthernStar would implement additional restoration or mitigation measures, as necessary. Additionally, NorthernStar has developed a *Noxious Weeds and Soil-borne Plant Disease Control Plan* to prevent the introduction and proliferation of noxious weeds during and after construction.

Unique or Sensitive Wildlife Habitats

Oregon Major Big Game Habitat

MPs 0.0 through 1.0 of the proposed pipeline route would be located within major big game habitat as mapped by Clatsop County. In addition, the proposed pipeline route between MPs 1.0 and 6.2 is mapped as peripheral big game range. Elk and deer tracks were observed near the proposed terminal site during a site visit, and black bear have been observed at the site by previous property owners. The *Clatsop County Comprehensive Plan* (Clatsop County, 1996) includes development standards for ODFW-identified big game areas. To minimize disturbance to wildlife, NorthernStar would establish signage along roads and instruct project personnel to reduce vehicle speeds along roads where big game, including Columbian white-tailed deer, occur to prevent vehicle-animal collisions. Project personnel would also be instructed not to approach big game (either adults or young) at any time. Sections 4.6.1.1 and 4.6.2 include additional discussion of the Columbian white-tailed deer.

Ducks Unlimited Waterfowl Management Area

From approximate MPs 6.0 to 8.1, the proposed pipeline would cross the Karamanos property, portions of which are managed by Ducks Unlimited as a waterfowl management area. NorthernStar has initiated consultation with the landowner and the Ducks Unlimited land manager regarding the proposed project (Karamanos, 2005; Lobdel, 2005). According to the landowner, Ducks Unlimited is funding the establishment of more wetland habitat with ponds over a 35-year period in the western and eastern portions of the property. To minimize impacts on waterfowl, NorthernStar would schedule construction activities between March and September, the period when waterfowl would be least likely to inhabit the property. In addition, because the Karamanos property is proposed for use as a mitigation site (the Peterson Point Mitigation Site), it is unlikely that the project would result in adverse impacts on the portion of the property managed by Ducks Unlimited (see section 4.5.2.3).

Westside Riparian-Wetlands

Approximately 1.8 acres of riparian forest habitat would be affected by the portion of the proposed pipeline in Washington. By definition, this vegetation community is a WDFW Priority Habitat. Approximately 85 percent of Washington's terrestrial vertebrate species use riparian habitat for essential life activities and the density of wildlife in riparian areas is comparatively high (Knutson and Naef, 1997). Forested riparian habitat has an abundance of snags that are critical to cavity-nesting birds and mammals and to many insectivorous birds. Downed logs are common within this habitat and provide cover and resting habitat for amphibians, reptiles, and small mammals. In addition, the relatively mild microclimate of riparian areas offers relief from hot, dry summers and cold, snowy winters which is especially important to species such as Columbian white-tailed deer and elk (Knutson and Naef, 1997). Riparian habitats form natural corridors that are important travel routes between foraging areas, breeding areas, and seasonal ranges, and provide protected dispersal routes for young (Knutson and Naef, 1997).

Based on the WDFW Priority Habitat classification, riparian habitats within the project area are also considered critical areas by Cowlitz County (as defined in Chapter 19.15 of the CCC) and warrant protection. Proposed mitigation for impacts on riparian forest is included in NorthernStar's Compensatory Mitigation Plan.

Mitigation Measures

As described in detail in section 4.5.2.3, the Peterson Point Mitigation Site would be the primary mitigation site for impacts on terrestrial wildlife in Oregon. The restoration of forested habitat at the Delameter Creek Mitigation Site would provide a net benefit to wildlife in the vicinity of the proposed project in Washington. However, as described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. To ensure that the mitigation proposed for the Bradwood Landing Project adequately compensates for project-related impacts, we have recommended that NorthernStar continue to consult with the appropriate natural resource agencies to finalize its Compensatory Mitigation Plan. The final Compensatory Mitigation Plan would be filed along with agency comments and applicable approvals with the Secretary prior to construction of the project.

4.6 THREATENED, ENDANGERED, AND OTHER SPECIAL STATUS SPECIES

Federal agencies are required by section 7 of the ESA (19 USC § 1536(c)), as amended, to ensure that any actions authorized, funded, or carried out by the agency do not jeopardize the continued existence of a federally listed endangered or threatened species, or result in the destruction or adverse modification of the designated critical habitat of a federally listed species. The action agencies (i.e., the FERC, COE, and Coast Guard) are required to consult with the FWS and/or NMFS to determine whether federally listed endangered or threatened species or designated critical habitat are found in the vicinity of the proposed project, and to determine the proposed action's potential effects on those species or critical habitats. For actions involving major construction activities with the potential to affect listed species or designated critical habitat, the federal agency must prepare a BA for those species that may be affected. The action agency must submit its BA to the FWS and/or NMFS and, if it is determined that the action would likely adversely affect a listed species, the federal agency must submit a request for formal consultation to comply with section 7 of the ESA. In response, the FWS and/or NMFS would issue a BO as to whether or not the federal action would likely jeopardize the continued existence of a listed species, or result in the destruction or adverse modification of designated critical habitat.

As the lead federal agency in conducting the NEPA analysis, FERC is also analyzing project-related activities authorized by the Coast Guard and the COE that could potentially affect federally listed endangered and threatened species. In compliance with section 7 of the ESA and the MSA, the FERC staff prepared a BA and EFH Assessment for the Bradwood Landing Project and submitted it to the FWS and NMFS in March 2007. Based on comments from the FWS and NMFS, the FERC staff is currently revising the BA and EFH Assessment and will resubmit the BA and EFH Assessment to the services with a request to initiate consultation. The BA and EFH Assessment details the environmental baseline for federally listed species, designated critical habitat, and EFH; direct, indirect, interdependent and interrelated, and cumulative effects; proposed conservation measures; and determinations of effect. A general summary of the information included in the BA and EFH Assessment is included in this EIS.

In addition to the federal ESA, the State of Oregon has endangered species provisions that protect native vertebrates and plants on state lands (ORS sections 496.172 to .192; 498.026; 564.100 to .135) and requires consideration of the impacts of forest practices on threatened and endangered species (ORS section 527.610). The State of Washington also has an endangered species law that covers animals (Wa. Rev. Code Ann. sections 77.08.010, 77.12.020, 77.16.040, 77.16.120, 77.21.010). Most species that are listed by these states as either threatened or endangered are also listed as federally threatened or endangered. Other special status species include those protected by the Migratory Bird Treaty Act and the MMPA.

For purposes of this environmental analysis, special status species of plants and animals include:

- species that are listed by the federal government as endangered or threatened, or are candidates for listing;
- species listed by Oregon and Washington as endangered, threatened, or candidates for listing;
- species listed under the MMPA;
- species listed under the Migratory Bird Treaty Act; and
- species identified by federal or state agencies as rare or sensitive with the potential to occur in the vicinity of the proposed project.

To assess potential impacts on special status species and designated critical habitat, the FERC staff (assisted by NorthernStar, as our non-federal representative) informally consulted with the FWS, NMFS, ODFW, WDFW, Oregon Natural Heritage Information Center (ORNHIC), and WDNR Natural Heritage Program (WNHP).

Table 4.6.1-1 identifies the special status species potentially occurring in the project area and describes the portion of the project area where the species may occur. The current status of species is discussed in section 4.6.1. Potential impacts on special status species and their designated critical habitat is discussed in section 4.6.2.

4.6.1 Current Status of Species

4.6.1.1 Federally Listed Threatened and Endangered Species

Fish

Informal consultation with the FWS and NMFS identified 13 federally listed threatened or endangered anadromous salmonid ESUs or DPSs, as well as the North American green sturgeon, as potentially occurring in the project area (see table 4.6.1-1). ESUs and DPSs are distinct populations of a species of fish or wildlife that interbreed when mature (Waples, 1991). Designated critical habitat for 12 of these ESU/DPSs is also present in the project area. Critical habitat has not been designated for the Lower Columbia River Coho salmon ESU or the Southern DPS of the North American green sturgeon.

Primary Constituent Elements (PCE), included in the critical habitat designation (70 Federal Register 52630 – 52858), essential to support one or more life stages of the ESU or DPS (sites for spawning, rearing, migration, and foraging) include:

- freshwater spawning sites with water quantity and quality conditions and substrate supporting spawning, incubation, and larval development;
- freshwater rearing sites with water quantity and floodplain connectivity to form and maintain physical habitat conditions and support juvenile growth and mobility; water quality and forage supporting juvenile development; and natural cover such as shade, submerged and overhanging large wood, log jams and beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks;
- freshwater migration corridors free of obstruction with water quantity and quality conditions and natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, side channels, and undercut banks supporting juvenile and adult mobility and survival;
- estuarine areas free of obstruction and water quality, water quantity, and salinity conditions supporting juvenile and adult physiological transitions between fresh and saltwater; natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, and side channels; and juvenile and adult forage, including aquatic invertebrates and fishes, supporting growth and maturation; and
- nearshore marine areas free of obstruction with water quality and quantity conditions and forage, including aquatic invertebrates and fishes, supporting growth and maturation; and natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, and side channels.

^a Denotes critical habitat for this species has been designated within the proposed project area.

^b Although the bull trout is federally listed as threatened, the NMFS has stated that it does not occur in the proposed project area (NMFS, 2006c); therefore, it is not included in the discussion of special status species.

^c Endangered status for the North Pacific right whale was proposed December 27, 2006 (71 FR 77694-77704).

^d The FWS proposed to remove the brown pelican from the list of endangered and threatened species due to recovery on February 20, 2008 (73 FR 9408-9433).

^e Critical habitat for the Pacific Coast DPS of the western snowy plover was proposed on March 22, 2004 (69 FR 75608-75656).

Detailed descriptions of designated critical habitat for the salmonid ESU/DPSs potentially affected by the project are provided in the BA and EFH Assessment for the Bradwood Landing Project. Sections 4.6.2.1, 4.6.2.2, and 4.6.2.3 provide summaries of designated critical habitat along the waterway for LNG traffic, at the LNG terminal, and along the pipeline route, respectively.

Each of the ESU/DPSs can be divided into ocean-type salmonids and stream-type salmonids. Ocean-type salmonid ESUs in the project area include one chum ESU and three Chinook ESUs (Lower Columbia River, Snake River Fall, and Upper Willamette River). Ocean-type subyearlings, known as fry, commonly spend weeks to months in rearing habitats before undergoing a physiological transition called smolting. Smolting develops the additional strength, energy, and reserve capacity required to adapt to and survive the physical and biological challenges of the ocean environment. Ocean-type smolts migrate downstream to and through the estuary as subyearlings, generally leaving the spawning and rearing area when they have reached a size of 3 to 4 inches. Because they undergo migration at a smaller size, ocean-type salmonids tend to form schools, presumably to reduce predation (Pitcher, 1986).

Stream-type salmonid ESU/DPSs in the project area include five steelhead DPSs (Upper Willamette River, Upper Columbia River, Middle Columbia River, Lower Columbia River, and Snake River Basin), two Chinook ESUs (Upper Columbia River Spring and Lower Snake River Spring/Summer), one sockeye ESU, and one coho ESU. Stream-type salmonids usually remain in the area from which they hatched for 1 year or more and migrate to the ocean as relatively large smolts (generally 4 to 12 inches). Duration and location of rearing varies by salmonid species; for example, steelhead may remain in freshwater for several years before migrating to the ocean, and sockeye rear in lakes rather than streams. As is the case with ocean-type salmonids, stream-type salmonid smolts undergo a physiological alteration in the spring that prepares them for migration and saltwater adaptation. Although the timing of migration varies by species, smolts tend to be spring migrants that pass quickly through the project area from early April to September, remaining in the area between a few days and weeks.

The larger size of the stream-type smolts allows them to occupy a wider range of habitats. Stream-type smolts are commonly found farther from shore with a deeper distribution than ocean-type migrants. Johnsen and Sims (1973) compared beach seine and purse seine catches of Chinook from fresh and brackish water sites in the lower Columbia River. The majority of Chinook collected from the shorelines by beach seine were in the range of 2.0 to 3.0 inches, while the majority of Chinook collected from deeper water by purse seine were in the range of 3.5 to 6.0 inches. These larger fish collected from offshore locations are the smolt-size juveniles characteristic of stream-type salmon.

The following sections discuss the life histories and existing conditions for salmonids identified by the FWS and NMFS as potentially occurring in the vicinity of the proposed project.

Chinook Salmon

Populations of Chinook, called “runs,” are grouped by the time they return to the rivers to begin their final spawning journey; spring, summer, fall, and winter. Although Chinook salmon can be found entering spawning rivers throughout the year, the majority return from April to December. Spawning and rearing times are dependent on the timing of the individual runs. Because of their large mature body size (approximately 30 pounds and 36 inches in length) (NOAA, 2007), Chinook salmon tend to use deeper water and larger gravel size to spawn than other salmonids. The female digs the nest, or redd, about 1 foot deep in areas with moderate to high velocity water. Most spawning and rearing activity takes place in the main stream channels immediately above the saltwater limit or hundreds of miles upstream. Depending on size, a female Chinook will produce 2,000 to 14,000 eggs, with an average of 5,000 eggs per female. Adults die soon after spawning.

Young Chinook salmon emerge from their redds in 3 to 5 months. Research shows that low dissolved oxygen levels and/or low water temperatures increase the length of time the eggs take to develop. The juvenile salmon grow and feed as they migrate downstream toward the ocean, stopping to rear in coastal estuaries for periods lasting up to 5 months before completing their migration to the open ocean. Most Chinook salmon smolts from the Pacific Northwest enter the ocean during their first year of life. Chinook salmon return to spawn in as little as 1 year, or may remain in the ocean for up to 9 years before returning to spawn. Chinook salmon are opportunistic and carnivorous feeders throughout their life, primarily feeding on insects, crustaceans, invertebrates, and other fish.

From April through November, sub-yearling ocean-type juvenile Chinook salmon inhabit the estuaries and intertidal areas of the Pacific Coast. These estuarine areas with fresh and saltwater wetlands and aquatic/riparian vegetation provide habitats that are crucial to juvenile Chinook salmon survival (Myers et al., 1998). Water quality within these areas is also crucial to their survival. Increases in siltation, changes in water temperature, and loss of riparian vegetation all have negative impacts on water quality (StreamNet, 2006). Finally, LWD provides deep, slow flowing pools and off-channel alcoves, creating cover from predators, protection from the sun, and feeding areas for juvenile Chinook.

Lower Columbia River Chinook

Both spring- and fall-run Chinook salmon comprise the ESU, but the majority are fall-run. Evidence from coded wire tag recoveries indicate that since 1960 the majority of the returning fall Chinook salmon on the Oregon side of the lower Columbia River are strays from Big Creek hatchery as well as Rogue River fall-run Chinook salmon released into Big Creek and the Youngs Bay area (Biological Review Team, 1997; Kostow, 1995). A significant portion of the naturally spawning Chinook salmon in Skamokawa Creek and Elochoman River are hatchery strays (WDFW, 2003). Long-term population trends for the Clatskanie River are positive, with an annual increase of 1 to 5 percent (Biological Review Team, 1997). However, trends for most of the other tributaries in the lower Columbia River are negative. The draft 2005 ODFW Oregon Native Fish Status Report indicates that naturally produced Lower Columbia River fall- and spring-run Chinook salmon in Oregon are currently at risk for extinction (ODFW, 2005).

Kostow (1995) designated three streams of the Lower Columbia-Clatskanie subbasin as containing habitat for spawning of fall Chinook: Hunt Creek, Plympton Creek, and the Clatskanie River. Hunt Creek is located adjacent to the LNG terminal site and is a tributary to the Columbia River. Plympton Creek is a tributary to the Westport Slough, which is crossed by the proposed pipeline. Clatskanie River is a tributary to the Columbia River, which is crossed by the proposed pipeline and is hydrologically connected to Westport Slough.

Eight to 10 historic populations in this ESU have become extirpated, most of them spring-run populations. Some natural production still occurs within the lower Columbia River in about 20 populations; however, only one population exceeds 1,000 spawners. High hatchery production continues to pose genetic and ecological risks to natural populations and masks their performance. Although the Clatskanie River population is an exception, most populations in this ESU have not substantially increased in recent years (Biological Review Team, 2003).

Upper Columbia River Spring-run Chinook

Upper Columbia River spring-run Chinook salmon populations exhibit an ocean-type life history (Taylor, 1990; Chapman et al., 1991; Chapman et al., 1994; Matthews and Waples, 1991; Waknitz et al., 1995). Spawning takes place in large, low-elevation streams (Schreck et al., 1986). Ocean-type fry west of the Cascade Crest emerge in April and May, and the majority rear from 1 to 4 months in freshwater

prior to emigrating to the ocean (Mullan, 1987; Olsen et al., 1992; Hymer et al., 1992; WDFW and Western Washington Treaty Indian Tribes, 1993; Chapman et al., 1994; Marshall et al., 1995). However, a small proportion of summer- and fall-run fish remain in freshwater until their second spring and emigrate as yearlings (Chapman et al., 1994; Waknitz et al., 1995). The proportion of yearling out-migrants varies from year to year, perhaps because of environmental fluctuations.

Upper Willamette River Chinook

Willamette Falls limits access of this ESU to the upper reaches of the Willamette River. High flows in the spring provide a window when returning salmon can ascend the falls, while low flows in autumn prevent fish from ascending the falls (Howell et al., 1985). Three major populations exist in the river above Willamette Falls, including the McKenzie River and the North and South Forks of the Santiam River (Kostow, 1995). Adult spring Chinook salmon enter the Columbia River in March and April, but they do not ascend Willamette Falls until May or June. Spawning generally begins in late August and continues into early October, peaking in September (Mattson, 1948; Nicholas, 1995; Willis et al., 1995). Approximately one-third of the habitat available to this run has been made inaccessible by the construction of dams, and the natural production areas for this ESU are limited.

Snake River Spring/Summer-run Chinook

The Snake River contains five principal subbasins that produce spring- and/or summer-run Chinook salmon (Columbia Basin Fish and Wildlife Authority, 1990). Three of the five principal subbasins (Clearwater, Grand Ronde, and Salmon Rivers) are large, complex systems composed of several smaller tributaries, which are further composed of many small streams. In contrast, the other two principal subbasins (Tucannon and Imnaha Rivers) are small systems in which the majority of salmon production occurs within the main rivers themselves. In addition to the five principal subbasins, three small streams provide small spawning and rearing areas (Columbia Basin Fish and Wildlife Authority, 1990). Snake River spring- and/or summer-run Chinook salmon have historically spawned in virtually all accessible and suitable habitat in the Snake River upstream from its confluence with the Columbia River (Evermann, 1896; Fulton, 1968).

Adult spring-run Chinook salmon enter the Columbia River and migrate upstream past Bonneville Dam (CRM 146) from March through May; summer-run Chinook salmon migrate during June and July. Snake River spring- and summer-run Chinook salmon tend to use small, higher elevation streams (headwaters). Snake River spring- and summer-run Chinook salmon exhibit a stream-type life history, and migrate swiftly to the ocean as yearling smolts (Schreck et al., 1986).

This ESU saw a large increase in returning salmon in many populations in 2001. However, recent abundance in this ESU is still short of the levels proposed in the recovery plan for Snake River salmon (NMFS, 1995b). The high level of both production/mitigation and supplementation hatcheries in this ESU leads to ongoing risks to natural populations and makes it difficult to assess trends in natural productivity and growth rate (Biological Review Team, 2003).

Snake River Fall-run Chinook

Adult Snake River fall-run Chinook salmon enter the Columbia River in July and August and reach the mouth of the Snake River between the middle of August and October. Spawning occurs in the mainstem and in the lower reaches of large tributaries in October and November. Based on what is known of Upper Columbia River fall-run Chinook salmon, juveniles in the Snake River presumably emerge from the gravel in March and April, and downstream migration usually begins within several weeks of emergence (Chapman et al., 1991). An overall average of 41 percent of the wild fish and 51

percent of the hatchery fish rear in mainstem Snake and Columbia River reservoirs, migrating out as yearling reservoir-type smolts the following year, with the remainder out-migrating as ocean-type sub-yearlings (Connor et al., 2005).

Fall-run Chinook salmon were widely distributed throughout the Snake River and many of its tributaries, from its confluence with the Columbia River upstream to Shoshone Falls, Idaho (Columbia Basin Interagency Committee, 1957; Haas, 1965; Fulton, 1968; Van Hynning, 1968; Lavier, 1976). The construction of 12 dams on the mainstem Snake River substantially reduced the distribution and abundance of the Snake River Fall-run Chinook salmon ESU (Irving and Bjornn, 1981). Fish passage facilities proved unsuccessful at several projects, and spawning habitats, particularly areas most frequently used by fall-run Chinook salmon, were eliminated with the formation of reservoirs.

Chum Salmon

Chum salmon spend more of their life history in marine waters than other Pacific salmonids. Chum salmon usually spawn in coastal areas, and juveniles out-migrate to the estuary almost immediately after emerging from the gravel that covers their redds (Salo, 1991). As discussed previously, this ocean-type migratory behavior contrasts with the stream-type behavior of some other species of salmonids. This means survival and growth in juvenile chum salmon depends less on freshwater conditions than on favorable estuarine conditions.

Mature chum salmon are fall-run fish and return to the lower reaches of coastal streams to spawn. Chum salmon usually migrate only a short distance upstream, to a point just upstream from the tidewater limit. Unlike other salmon, chum are not strong jumpers, so they are often found distributed downstream from significant barriers in spawning streams. The female lays about 2,000 to 4,000 eggs in a redd and will guard her nest until her death a short time later, about 11 to 15 days after entering freshwater. Chum salmon eggs hatch between December and February and the juvenile chum salmon emerge from the gravel in 1 to 2 months, depending on stream temperature. They quickly migrate downstream to the estuary, feeding on insect larvae in the stream during their journey. Chum salmon juveniles are common in estuaries from January through July (StreamNet, 2006).

Very little research has been done on the Columbia River runs of chum salmon and there is not much known about the status of this species. Historically, chum salmon spawned in the lower reaches of several streams within the lower Columbia-Clatskanie subbasin.

Observations of chum salmon fry are often more difficult to make than are observations of juveniles of other salmonids because chum salmon out-migrants: 1) are smaller than out-migrants of other salmonids; 2) migrate at night; 3) usually have less distance to migrate before reaching saltwater than do other species; and 4) do not school as tightly as some other salmonids. Downstream migration may take only a few hours or days in rivers where spawning sites are close to the mouth of the river or it may take several months.

Kostow (1995) cited a dramatic decline in run sizes within the Columbia River, noting that the 1992 commercial harvest landed about 700 fish, whereas harvest prior to the 1940s ranged from 100,000 to 600,000 fish annually. Most of the production of chum salmon within the lower Columbia River is from streams on the Washington side of the river and the mainstem Columbia River below Bonneville Dam (CRM 146) (Ehlke and Keller, 2003). Chum salmon have been reported in October in the Washougal, Lewis, Kalama, and Cowlitz Rivers in Washington and the Sandy River in Oregon (Salo, 1991). However, the NMFS does not recognize any naturally spawning populations of chum salmon in Oregon (Johnson et al., 1997). Since 1995, there have been no recreational or directed commercial harvests of chum salmon within the Columbia River (Johnson et al., 1997).

Coho Salmon

Coho generally spawn in the tributaries and headwater streams of large rivers, preferably in areas with low water velocity and small-sized gravel. The female digs from one to four redds and generally spawns with different males in each redd, producing 1,000 to 5,000 eggs. Coho die soon after spawning. The eggs hatch in about 1 month and juveniles emerge from the gravel in about 2 to 5 weeks. Juvenile coho usually remain in freshwater for 1 year, moving in and out of side-channels, sloughs, beaver ponds, and tributary streams, seeking food and shelter from the high winter currents (Weitkamp et al., 1995). Although they may begin their migration downstream from April through August, most migrate downstream approximately 1 year after emerging from the gravel (Weitkamp et al., 1995). Coho salmon generally spend 2 days to 1 month in the estuary, feeding and adapting to saltwater before entering the open ocean. Coho generally spend 2 years in the ocean, returning to natal streams to spawn in their third year of life. A small percentage of the coho, usually less than 5 percent of the population, will return early after only 1 year in the ocean and are known as “jack salmon” (Weitkamp et al., 1995).

The coho salmon is a carnivorous and opportunistic feeder throughout its life, feeding primarily on insects, invertebrates, and crustaceans when young, and on other fish and squid when in the open ocean. Like other salmonids, including Chinook, juvenile coho require LWD to provide deep, slow flowing pools that create cover from predators, protection from the sun, and feeding areas.

Spawning of adult coho is largely dependent on streamflows, with most of the population in the lower Columbia River spawning when there is an increase in or maximal streamflow. Generally, adult Lower Columbia River coho salmon can be found migrating to their natal streams between June and February and spawning from September through March (Weitkamp et al., 1995; Good et al., 2005; WDFW, 2003; Wade, 2000, 2002).

Coho salmon from the Lower Columbia River ESU are mostly hatchery produced individuals. Only within the Clackamas and Sandy Rivers of the Columbia River ESU are natural populations known to be found (Good et al., 2005). The 2001 Biological Review Team review of the coho ESU in the lower Columbia River indicated that the vast majority, over 90 percent, of the historical populations appear to be either extirpated or nearly so.

Sockeye Salmon

The sockeye salmon is an anadromous fish with a stream-type life history that spawns and rears in freshwater lakes and streams. The life history of sockeye is variable throughout the Pacific Northwest, depending largely on the region of origin and local stream conditions. Migration into freshwater to spawn commonly occurs between June and August, with spawning taking place August through December. Most sockeye migrate great distances up freshwater streams, through lakes, and into tributary streams, although some sockeye do spawn in the shores of freshwater lakes (Gustafson et al., 1997).

Sockeye salmon are native to the Snake River and historically were abundant in several lake systems in Idaho and Oregon (Gustafson et al., 1997). In this century, a variety of factors have led to the demise of all Snake River sockeye salmon except those returning to Redfish Lake in the Stanley Basin of Idaho. Adults migrate upstream to Redfish Lake between July and September. Juveniles migrate downstream from Redfish Lake during April and May (Dolat, 1997).

Snake River sockeye salmon are unique in that they are the longest migrating sockeye salmon population in the world, traveling up to 900 miles to the high elevation lakes where they spawn. Since becoming listed as an endangered species in 1991, hatchery programs have begun to assist recovery efforts for the population (Good et al., 2005).

Steelhead

Steelhead are listed on a DPS basis, which is analogous to the salmonid ESU designations. Steelhead is the name commonly applied to the anadromous form of the biological species *Oncorhynchus mykiss*. The anadromous form of steelhead is under the jurisdiction of NMFS, while the resident freshwater forms, usually called rainbow or redband trout, are under the jurisdiction of the FWS. Steelhead exhibit one of the most complex suites of life history traits of any species of Pacific salmonid. Unlike other salmonids, steelhead can spawn more than once (iteroparous), whereas all other salmonids discussed spawn once then die (semelparous). The anadromous steelhead may spend up to 7 years in freshwater before smoltification and up to 3 years in saltwater before returning to spawn. Spawning migrations occur throughout the year, with seasonal peaks of activity. In a given river basin, there may be one or more peaks in migration activity. Large rivers, such as the Columbia River, may have migrating adult steelhead at all times of the year.

Steelhead can be divided into two basic reproductive ecotypes based on the state of sexual maturity at the time of river entry and duration of spawning migration (Burgner et al., 1992). The stream-maturing type enters freshwater in a sexually immature condition between May and October and requires several months to mature and spawn. The ocean-maturing type enters freshwater as a mature adult between November and April and spawns shortly thereafter. Steelhead found in the Columbia River are almost exclusively stream-maturing and generally spawn farther upstream than ocean-maturing steelhead.

Lower Columbia River Steelhead

This DPS occupies streams and tributaries to the Columbia River between the Cowlitz and Wind Rivers, Washington (inclusive), and the Willamette and Hood Rivers, Oregon (inclusive). Excluded are steelhead populations in the upper Willamette River Basin above Willamette Falls, Oregon and the Little and Big White Salmon Rivers, Washington. This DPS comprises both winter- and summer-run steelhead. Genetic data show distinction between steelhead of this DPS and adjacent regions, with a particularly strong difference between coastal and inland steelhead in the vicinity of the Cascade Crest (Busby et al., 1996). The majority of stocks within this DPS, for which data is available, have been declining in the recent past, but some have been increasing strongly (Busby et al., 1996; Good et al., 2005).

Middle Columbia River Steelhead

Almost all steelhead populations within this DPS are summer-run fish, with two winter-run exceptions in the Klickitat River and Fifteenmile Creek watersheds. A balance between 1- and 2-year-old smolt out-migrants characterizes most of the populations within this DPS. Adults spend between 1 and 2 years in the ocean before returning to spawn.

Production within the Middle Columbia River steelhead DPS has declined due, in part, to losing spawning habitat because of low flows. Loss of riparian habitat and in-stream structure are also threats to the Middle Columbia River steelhead. Blockages have prevented access to sizable steelhead production areas in the Deschutes and White Salmon Rivers. While there are hatchery facilities located within the drainages of the DPS, there are also stocks within the DPS that have had little or no supplementation from hatcheries.

Upper Columbia River Steelhead

All of the steelhead in this DPS are summer-run fish. Upper Columbia River steelhead return to the Columbia River in the later summer and early fall; most migrate relatively quickly up the mainstem of the river to their natal tributaries. A portion of the returning run over-winters in the mainstem reservoirs,

passing over the upper dams in April and May of the following year. Spawning occurs in the late spring of the calendar year following entry into the river. Upper Columbia River steelhead smolt out-migrants are predominantly 2- and 3-year-old juveniles. Most adult steelhead return after 1 or 2 years at sea, starting the cycle again (Busby et al., 1996).

Current abundance of the Upper Columbia River steelhead, both natural and hatchery produced, have increased in recent years. The average return through Priest Rapids Dam from 1997 through 2001 was 12,900 fish, while the average for the previous 5 years (1992 through 1996) was 7,800 fish. Most returns to the upper Columbia River are hatchery origin fish. Wild fish estimated during this period averaged 2,200 fish, more than double the average from the previous 5-year average of 1,040 fish.

Upper Willamette River Steelhead

This DPS occupies the Willamette River and its tributaries upstream from Willamette Falls. The native steelhead of this basin are late-migrating winter steelhead, entering fresh water primarily in March and April (Busby et al., 1996). This unusual run timing appears to be an adaptation for ascending Willamette Falls, which functions as an isolating mechanism for upper Willamette River steelhead. Early migrating winter steelhead and summer steelhead have been introduced to the upper Willamette River basin and, since naturally spawned steelhead are defined as part of the DPS, some populations (particularly early spawning fish in Coast Range subbasins) may represent introduced stocks. On average, native winter steelhead within this DPS have been declining since 1971 and have exhibited large fluctuations in abundance (ODFW, 2005).

Snake River Basin Steelhead

The Snake River Basin steelhead DPS is comprised of a diversity of steelhead populations with more similar genetic make-up to each other than to those steelhead that spawn outside of the Snake River basin. The Snake River Basin steelhead DPS spawn at high elevations (up to 6,500 feet) and migrate up to 900 miles to their spawning locations. Within this DPS, all steelhead are summer-run fish, but they are divided into two ecotypes, commonly referred to as either A-run or B-run. A-run fish are defined as passing Bonneville Dam before August 25 and B-run fish pass Bonneville Dam after August 25 (Busby et al., 1996). Adult A-run steelhead enter freshwater from June through August and are smaller than B-run fish, which enter freshwater from late August through October. Most of the steelhead populations in the Columbia River basin east of the Cascade Range are A-run fish. B-run steelhead are thought to be produced only in the Clearwater, Middle Fork Salmon, and South Fork Salmon Rivers (Busby et al., 1996). Much of the Snake River Basin steelhead DPS is currently composed of hatchery fish.

North American Green Sturgeon

The Southern DPS of North American green sturgeon is federally listed as threatened. Based on spawning locations, two DPS have been designated for this species: the Southern DPS and the Northern DPS. The Northern DPS spawn in the Rogue, Klamath, Trinity, and Eel Rivers in Oregon and California, and the Southern DPS only spawn in the Sacramento River, California.

Green sturgeon are anadromous and occur along the west coast of the United States and Canada (Erickson and Hightower, 2007). They are the most marine of all sturgeon species (Adams et al., 2006). Migration behaviors and distinctions between non-spawning locations for each DPS are unclear. Both the Northern and Southern DPS have been identified by genetic analysis in the Columbia River and associated estuaries in Oregon/Washington. In the Columbia River system, sturgeon concentrate in the estuaries during summer months. They have been known to travel upriver as far as the Bonneville Dam, but do not spawn in the river (Israel et al., 2004). Green sturgeon abundance is relatively high in the

Columbia River estuary system compared to other estuaries on the west coast of the United States (NOAA, 2006G).

Juveniles spend 1 to 3 years in freshwater before migrating to near coastal habitats between late summer and early winter (Israel et al., 2004; Erickson and Hightower, 2007; Adams et al., 2006). Mature adults (13 to 20 years old) return to natal rivers during the summer every 3 to 5 years, where they broadcast spawn their eggs over the surface of river cobbles (Israel et al., 2004; Adams et al., 2006). Green sturgeon feed on benthic invertebrates and tend to be nocturnal (Israel et al., 2004). When at sea, sturgeon are found over shallow continental shelf areas (less than 300 feet deep) and are often concentrated in specific areas off the coasts of Oregon and Washington (Erickson and Hightower, 2007).

Sea Turtles

Four species of sea turtles have been documented off the coasts of Oregon and Washington and are federally listed as threatened or endangered under the ESA. These include the green, olive ridley, leatherback, and loggerhead sea turtles. Sea turtles nesting on beaches in the United States are under the jurisdiction of the FWS; sea turtles occurring in U.S. waters are under the jurisdiction of the NMFS. None of the listed sea turtles are known to nest along the Pacific Coast of the United States (NMFS and FWS, 1998a; 1998b; 1998c; 1998d).

All four species of sea turtles potentially affected by the project are highly migratory. Eastern Pacific populations of sea turtles generally spend the winter months in breeding grounds off of southern Mexico and Central America, and although sea turtles have been reported during the summer months as far north as Alaska, occurrences are more common in southern California and northern Mexico (NMFS and FWS, 1998a, 1998b, 1998c, and 1998d).

Although sea turtles are generally considered a warm temperate marine reptile; green, olive ridley, leatherback, and loggerhead sea turtles have been recorded off the coasts of Oregon and Washington in the last 10 years (Green et al., 1992). Green et al. (1992) conducted a study to assess the presence and abundance of federally listed species off the Pacific Coast of the United States. This study collected both aerial and shipboard marine fauna data along the Washington and Oregon coasts between 1989 and 1990. During this time, 16 sea turtles were observed; all sightings were leatherback sea turtles and all occurred between June and September, when water temperatures are warmest. Most (62.5 percent) of these sightings occurred over the continental slope waters, with the remainder found over the continental shelf.

The diets of sea turtles vary greatly. Green sea turtles are known to be generally herbivorous; the foraging habits of olive ridley sea turtles are largely unknown, although crustaceans are believed to be a major part of their diet; loggerhead sea turtles primarily forage on benthic invertebrates; and leatherback sea turtles forage on cnidarians and tunicates (NMFS and FWS, 1998a, 1998b, 1998c, and 1998d).

Whales

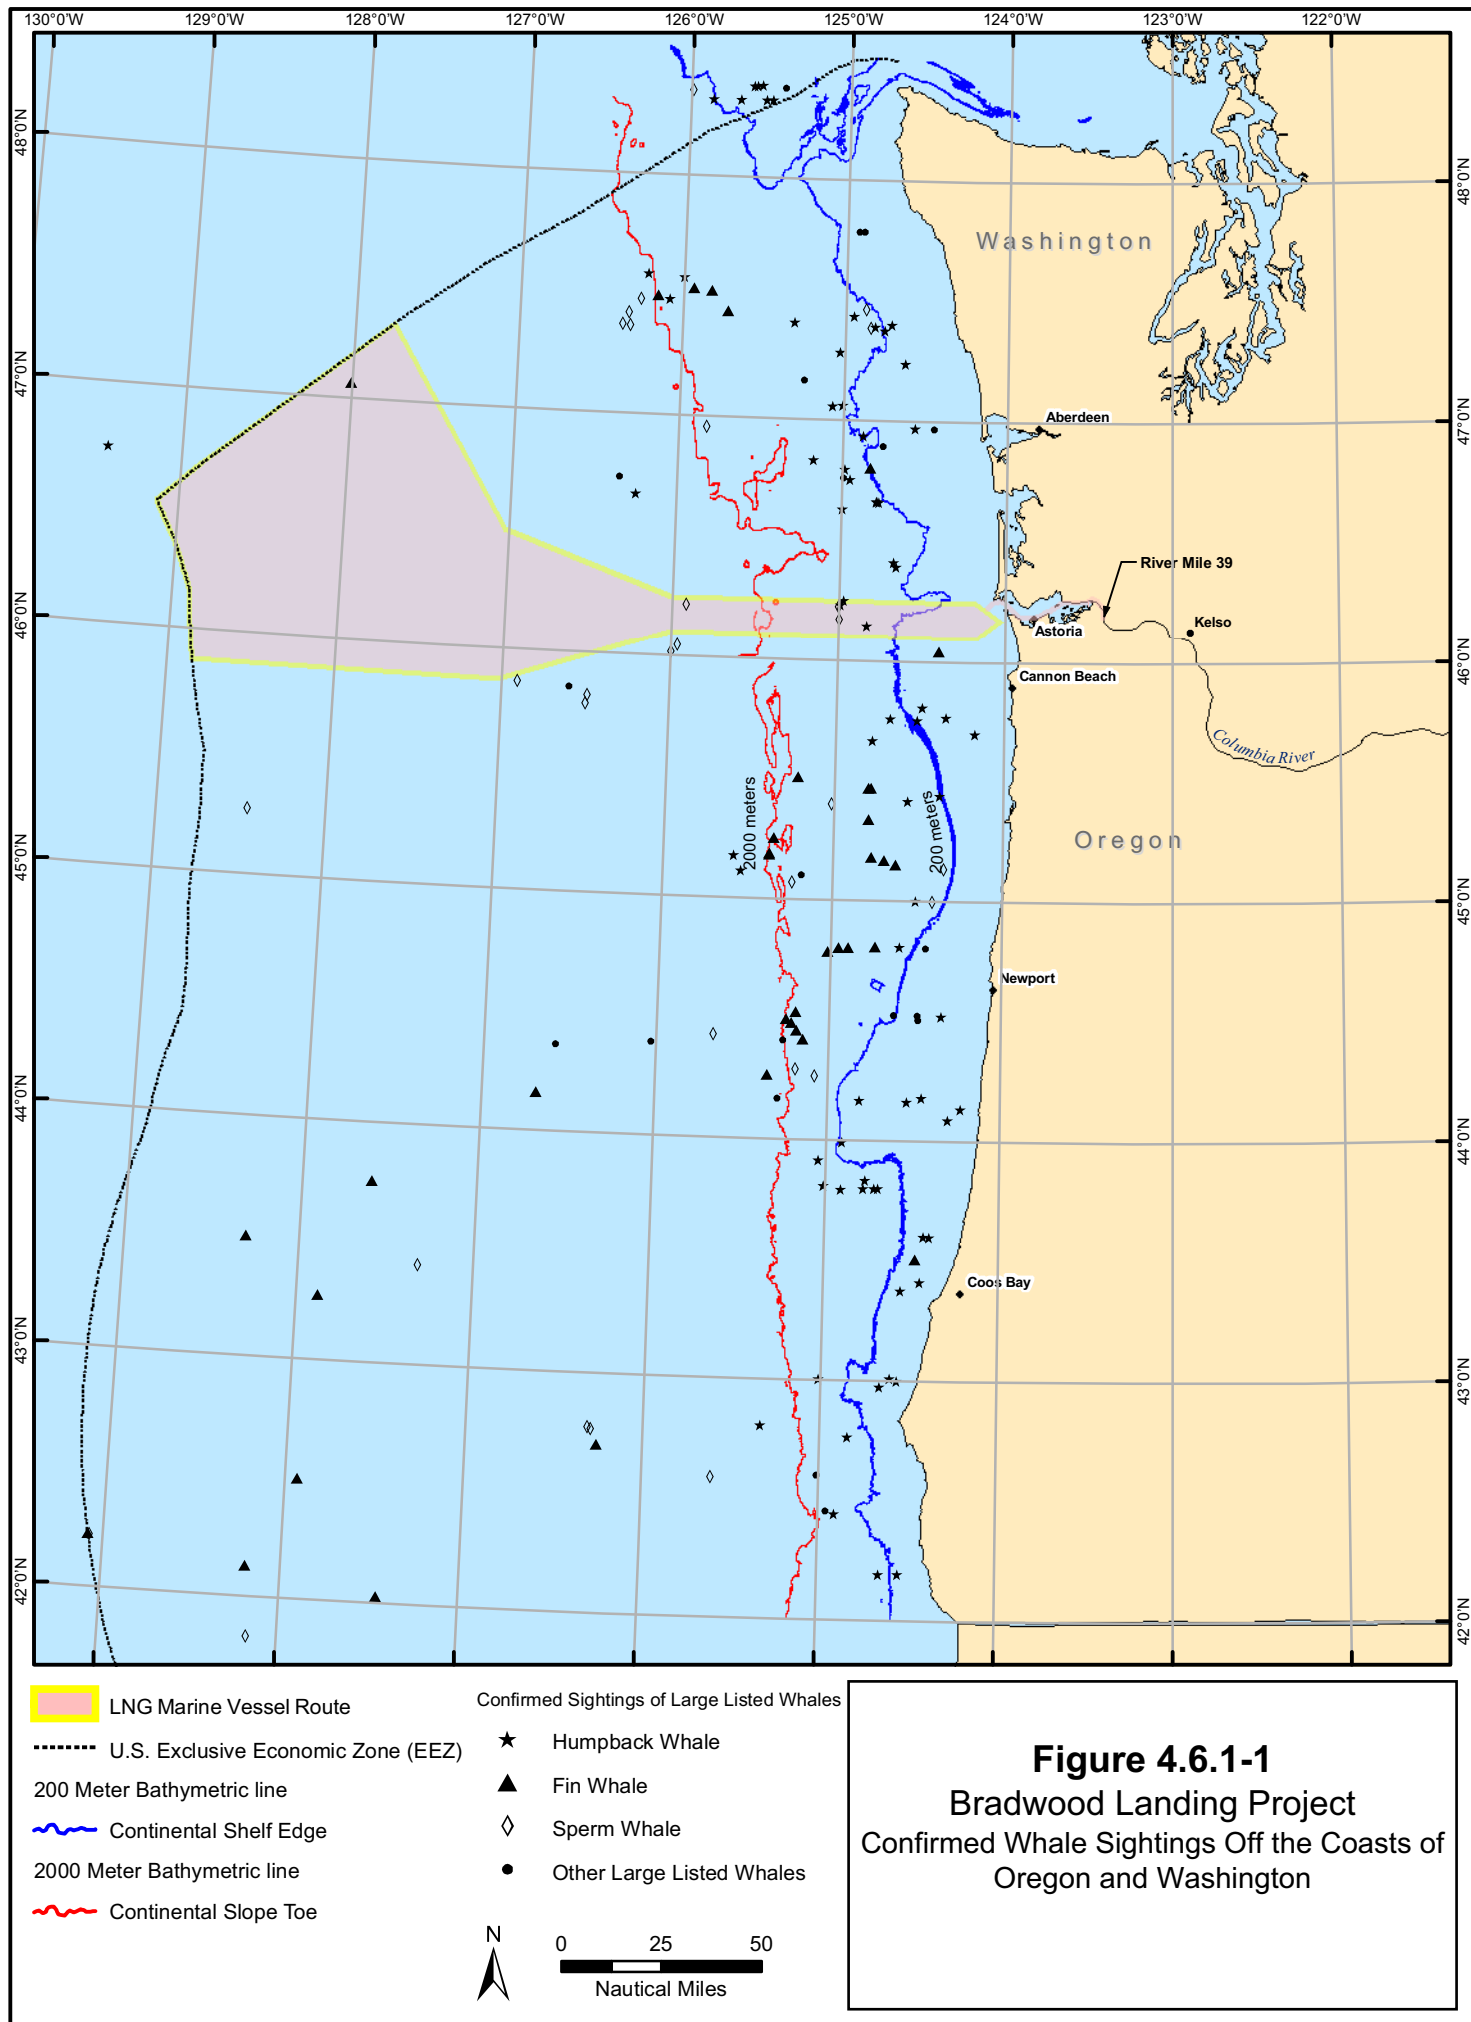

Seven species of whales potentially occur off the coasts of Oregon and Washington that are federally listed as endangered under the ESA (these species are also protected under the MMPA). These include the blue, fin, humpback, North Pacific right, sei, Southern Resident killer, and sperm whales. Whales tend to feed during the summer in the northern latitudes and migrate to the tropical southern latitudes in the winter for breeding. Some whales do not migrate as far north as the rest of the population; therefore, whales can be encountered throughout the year off the coasts of Oregon and Washington.

As depicted in figure 4.6.1-1, marine mammal aerial and shipboard surveys have been conducted in the waters off of Oregon and Washington to determine marine species distribution, abundance, and habitat use patterns. In addition, opportunistic sighting data compiled by the NMFS National Marine Mammal Laboratory's Platform of Opportunity Program (POP) was also used to assess whale distribution. The POP database has been collecting opportunistic data since 1958. Based on the distribution data from both the POP database and the Green et al. 1992 study, beyond the base of the continental slope, marine mammal sightings become increasingly rare compared to sightings along either the slope or shelf. The sperm and sei whales, which are known to have a more oceanic (deeper depth) distribution than other whale species, are exceptions to this pattern.

The blue whale, a baleen whale, is the largest animal ever known to have lived on Earth. Blue whales are found in all oceans worldwide. Blue whales in the Pacific Coast region are part of the Eastern North Pacific Stock, which contains an estimated 1,186 whales (Caretta et al., 2007). Blue whales spend about one-half their time outside the EEZ (Caretta et al., 2007). Blue whales forage in portions of the LNG carrier transit route off of California, British Columbia, and/or the Gulf of Alaska. In addition, blue whales occur throughout the EEZ between June and November prior to migrating south. Unpublished satellite data shows blue whales migrating north/south offshore of the Columbia River mouth, although the distance from the mouth was not known at the writing of this EIS (Calambokidis, 2006).

The fin whale is a baleen whale with populations centered in the temperate zones of both the northern and southern hemispheres. Fin whales found off the Pacific Coast are part of the California/Washington/Oregon Stock. Ship surveys conducted off the Pacific Coast estimated the population to be 3,454 whales (Caretta et al., 2007). Acoustic signals from fin whales are detected year-round off the coasts of northern California, Oregon, and Washington, with peak numbers occurring in the summer and fall (NMFS, 1998). Recent observations show aggregations of fin whales off the coast of Oregon during the summer months (Caretta et al., 2007). Although it has been determined that fin whales are migratory, the pattern of migration is apparently complex, and not well-understood. For example, fin whales occur year-round in some areas (such as the Pacific Coast), but the density of individuals in an area changes seasonally (NMFS, 1998). Although their distribution and migratory patterns are not well understood, 78 percent of the 27 fin whale sightings recorded by Green et al. (1992) and all 9 sightings recorded in the POP database occurred over the slope.

The humpback, one of the large baleen whales, occurs in all oceans of the world, although it is less common in Arctic regions. The Eastern North Pacific Stock resides along the Pacific Coast in the summer and fall months and spends the winter and spring in coastal Central America and Mexico (Caretta et al., 2007). Caretta et al. (2007) provided a best estimate of abundance for the population of humpbacks in California, Oregon, and Washington coastal waters of approximately 1,396 whales. The humpback whales of the Pacific Coast have generally increased in abundance since the taking of humpback whales was prohibited in 1966. Humpback whales occur throughout the EEZ between May and November, with the higher concentrations occurring near abrupt changes in bathymetric relief. Humpback whales congregate near the shelf edge, especially near Heceta Bank in Oregon and submarine canyons in Washington (Green et al., 1992). Of the 68 humpback whale sightings recorded during the Green et al. (1992) study, 41 percent occurred over the shelf, 57 percent occurred over the slope, and 2 percent occurred offshore. The POP database recorded 22 sightings; of these, 29 percent occurred over the shelf, 52 percent occurred over the slope, and 19 percent occurred offshore.

The North Pacific right whale historically ranged across the entire North Pacific Ocean. The current status of this species is unknown but is thought to number only in the tens of animals. Between 1900 and 1994, only 29 verifiable sightings occurred along the Pacific Coast and Hawaii (Caretta, et al., 1995). Recent sightings of the North Pacific right whale have occurred in the Bering Sea and Northern Gulf of Alaska near Kodiak Island. North Pacific right whales are known to occur in the southeast Bering Sea and the northern Gulf of Alaska. The right whales that have been found here have been predominantly males, but at least one female has been identified by genetic analysis of a biopsy sample (LeDuc, 2004). Little else is known about the North Pacific right whale's current state, including whether the whales known to occur in the Bering Sea are all that remain of the entire population, or if they are just one portion of the eastern population, with the rest of the population occurring elsewhere during summer months. Additionally, little, if anything, is known about the route that North Pacific right whales take on their migration south.

The sei whale is a baleen whale with a similar life history, appearance, and distribution as the fin whale. Sei whales occurring off the Pacific Coast are part of the Eastern North Pacific Stock. Generally occurring in offshore waters, sei whales do not appear to be associated with coastal features, which partially accounts for the low frequency of observations in the shelf waters of Oregon and Washington (NMFS, 1998; Caretta et al., 2005). The sei whale abundance estimate for California, Oregon, and Washington waters out to 300 nautical miles is approximately 43 whales (Caretta et al., 2007). Migration of the Eastern North Pacific Stock is between coastal waters of the Pacific Coast and Vancouver Island (Rice, 1977). Sei whales have been recorded within the EEZ during the summer months. The POP database includes four sightings of sei whales since 1958. Of these, one sighting occurred in shelf waters, one occurred along the slope, and two occurred offshore. However, shipboard surveys between 1991 and 2001 did not record any sightings of the sei whale within the EEZ (Caretta et al., 2005; Green et al., 1992).

The Southern Resident killer whale, a toothed whale, occurs in all oceans and seas of the world, although it prefers the colder waters of both hemispheres. The greatest abundances of killer whales occur within 500 miles of the continents (Mitchell, 1975). Killer whales inhabiting the inland and coastal waters of Oregon and Washington are part of the Eastern North Pacific Southern Resident Stock. This stock is comprised of three pods, one occurs in inland waters, and the other two spend more time offshore (Ford et al., 2000). However, most sightings of these resident whales occur during the summer months in inland waters of Washington and southern British Columbia. This stock has been intensely studied and contained an estimated 88 whales as of November 2007 (Center for Whale Research, 2008). The Southern Resident killer whale DPS occurs mainly within the inland waters of Washington. However, during the winter of 2005 and 2006, Southern Resident killer whales were documented daily at the mouth of the Columbia River (Calambokidis, 2006).

The sperm whale, a toothed whale, is found throughout the northern Pacific Ocean, and has been seen in every season except winter off the coasts of Oregon and Washington (Green et al., 1992). Sperm whales found off the coasts of Oregon and Washington are part of the California-Oregon-Washington Stock, which contains about 2,265 individuals (Caretta et al., 2007). Sperm whale abundance appears to have been rather variable off the coast of California between 1979/1980 and 1996, but does not show any obvious trends. Large populations of sperm whales are known to occur both west and south of the California-Oregon-Washington stock; however, there is no evidence of sperm whale movements into this region from either the west or south (NMFS 2006f). Sperm whales are known to occur in both the open offshore portions of the EEZ and along the slope. Of the 36 recorded during the Green et al. (1992) study, 11 percent occurred over the slope and 89 percent occurred offshore. The POP database had 10 sightings and, of those, 7 occurred over the slope and 3 occurred offshore.

Steller Sea Lion

The Steller sea lion is federally listed as endangered under the ESA, is listed as threatened by the State of Washington, and is protected under the MMPA. The largest of the eared seals, which includes sea lions and fur seals, the Steller sea lion occurs along the rim of the northern Pacific Ocean (NMFS, 1992). Steller sea lions occurring near the project area are part of the Eastern DPS, which extends from southeastern Alaska to northern California. In 2002, the total population of the Eastern DPS was estimated to be 47,885 (Pitcher, ADFG, NMFS unpublished data). The numbers of Steller sea lions in Oregon and Washington have increased in recent years, with Oregon counts increasing at an average rate of 3.7 percent per year since 1977, and Washington counts increasing an average of 9.2 percent per year since the early 1990s (LCFRB, 2004).

Steller sea lions occur throughout the year in Oregon and Washington. Although not known to migrate, Steller sea lions disperse widely outside of the breeding season. Recent tagging efforts have shown that Steller sea lions move between the mouth of the Columbia River and the Bonneville Dam at CRM 146, foraging for food (Stansell et al., 2007). Rookeries occur in a wide variety of areas, but most locations have specific favorable characteristics, including slightly sloped topography, protection from the wind, and isolation from humans and other mammalian predators. Rookeries are occupied from late May through early July, with females arriving about 3 days before the pup is born (NMFS, 1992). Females generally exhibit site fidelity, and rookery locations change little from year to year (NMFS, 1992). No breeding territories (or rookeries) are located in Washington, but five Steller sea lion rookeries occur in Oregon, including Rogue Reef, Sea Lion Caves, Three Arch Rocks, and both Long Brown Rock and Seal Rock at Orford Reef. The nearest rookery to the proposed project is at Three Arch Rocks, which is about 60 miles south of the mouth of the Columbia River.

Haulout sites are locations used by breeding, non-breeding, and subadult sea lions during the non-breeding season, and are generally associated with jetties, offshore rocks and islands, logbooms, marina docks, and navigation buoys (NMFS, 1992; LCFRB, 2004). Similar to rookeries, sea lions show a high degree of site fidelity to haulouts. The nearest haulout site to the proposed project is the South Jetty near the mouth of the Columbia River, which is used by hundreds of sea lions every year (LCFRB, 2004). Use of the South Jetty is lowest in the spring and summer, when adults return to rookeries for pupping and breeding, and increases in fall and winter when animals move to haulouts and forage on salmonids and eulachon. The only other haulout site used by Steller sea lions in the vicinity of the lower Columbia River is the Large Navigation Buoy, which is located about 6 miles into the Pacific Ocean (Jeffries et al., 2000). Recent surveys by the WDFW documented 1,000 Steller sea lions near the mouth of the Columbia River (WDFW, 2007).

Columbian White-tailed Deer

The Columbian white-tailed deer, listed as endangered both federally and in Washington, is the westernmost subspecies of the white-tailed deer. Currently, there are two Columbian white-tailed deer DPSs, one is located in Douglas County, Oregon, and the other is located along the lower Columbia River in Oregon and Washington (Brown, 2003; Smith et al., 2003). Current population estimates for subpopulations of the Columbian white-tailed deer along the lower Columbia River are provided in table 4.6.1-2. Population density is estimated at about 25 to 75 deer per square mile (Clark, 2006).

TABLE 4.6.1-2	
Population Estimates for the Columbian White-tailed Deer along the Lower Columbia River	
Location	2005 Population
Julia Butler Hansen National Wildlife Refuge	
Washington Mainland	100
Tenasillahe Island	100
Wallace Island	25
Crims Island	25
Puget Island	125
Westport Bottomlands	120
Clatskanie Lowlands	25
Fisher Island and Willow Grove	25
Lord Island and Diblee Flats	20
Source: Clark, 2006.	

The majority of deer within the Columbia River population are included in one of four subpopulations (Washington mainland, Tenasillahe Island, Puget Island, and the Oregon lowlands). Each subpopulation is geographically separated by major channels of the Columbia River (WDFW, 2004). Both the Washington mainland and Tenasillahe Island subpopulations occur within the JBHNR, which was established in 1972 (and was then called the Columbian White-tailed Deer National Wildlife Refuge) to protect over 5,600 acres of shoreline and island habitat for the preservation of the Columbian white-tailed deer (WDFW, 2004). These subpopulations are both currently considered secure and viable. The Oregon lowlands subpopulation is located near the community of Westport and reportedly further upstream in the Clatskanie lowlands (FWS, 1983; Clark, 2006). There are also plans to establish another subpopulation on Crims Island, and another subpopulation is being planned on a group of islands including Fisher, Hump, Lord, and Walker islands (FWS, 2005a). This group of islands is located approximately 1 mile upstream of the Crims Island subpopulation and the two subpopulations are expected to merge in the future (FWS, 2005a).

Columbian white-tailed deer typically inhabit forested areas located along waterways and generally select areas that offer both food and cover (Davison, 1979; Verts and Carraway, 1998). Sitka spruce with a grass understory is used most frequently; however, in summer, Columbian white-tailed deer preferentially inhabit mixed forests of western red cedar, red alder, and Sitka spruce with a grassy understory (Suring and Vohs, 1979). Pastures are generally avoided, presumably due to limited cover (Verts and Carraway, 1998). In a study conducted by Smith (1987), density of deer was greatest in areas where woodland cover was greater than 50 percent. Foraging habitat used by Columbian white-tailed deer is generally located within 820 feet of forest cover, and varies greatly with season. Typical forage includes evergreen blackberry, Pacific ninebark, red-osier dogwood, salal, juniper, western red cedar, foxtail, orchard grass, tall fescue, mannagrass, yarrow, red clover, and buttercup (Dublin, 1980). However, Dublin (1980) found that between 25 percent and 50 percent of the diet was comprised of woody browse species between September and February.

Fawning begins at the beginning of June and ends in mid- to late-July (ODOT, 2006; Watson and Schirato, 1990). Peak fawning occurs in mid- to late-June (FWS, 2003). Habitats used for fawning include fields of tall grasses and other habitats that provide thermal and hiding cover and are located away from other deer (Clark, 2006). After birth, the doe goes about her usual activities, returning several times a day to nurse the newborn fawns (Clark, 2006). The young fawns will generally rest or hide during the day in the same location where they were born or may be moved one or more times by the mother (Clark,

2006). Fawns typically are weaned after 10 weeks, although some may continue nursing into autumn (Verts and Carraway, 1998).

Brown Pelican

On February 20, 2008, the FWS proposed to remove the brown pelican from the list of endangered and threatened species due to recovery (73 Federal Register 9408–9433). The brown pelican is currently listed federally and by the states of Oregon and Washington as endangered. The brown pelican occurs along the Pacific Coast between California and Chile (FWS, 2006f). Habitat of the brown pelican is mainly coastal; they are rarely seen inland or far out at sea (FWS, 2006g). Pelicans nest in colonies that are usually located on coastal islands, on the ground, or in small bushes and trees (Palmer, 1962). Nests are composed primarily of grasses, reeds, sticks, and straw and are situated to avoid mammalian predators. This species is not known to breed in Oregon; however, the mouth of the Columbia River supports one of the largest non-breeding communal roosts in the United States. In 2002, as many as 11,000 brown pelicans roosted on East Sand Island at the mouth of the Columbia River between late spring and early fall (FWS, 2008). Brown pelicans roosting in this area feed mostly in shallow portions of the estuary but may sometimes occur up to 40 miles from shore. Their diet consists of various fishes, especially sardines (*Sardinops* spp.), mullet (*Mugil* spp.), and anchovies (*Engraulis* spp.) (FWS, 2005b).

Marbled Murrelet

The marbled murrelet is listed federally and by the states of Oregon and Washington as threatened. Marbled murrelets breed along the Pacific Coast of the United States between Alaska and central California. In the Pacific Northwest, marbled murrelets nest solitarily on mossy platforms on large branches in mature conifer forests within 20 to 50 miles of the coast (Lank et al., 2003; FWS, 1997). Nest stands utilized by marbled murrelets typically have multiple canopy layers, moderate to high canopy closure, and are composed of Douglas-fir, Sitka spruce, and western hemlock. Marbled murrelets nest high in large trees (minimum of 30 inches diameter at breast height) with large, moss-covered branches that serve as nest platforms (Burger, 2002; Nelson and Wilson, 2002). Forests with trees older than 150 years are thought to provide the best structures for suitable nesting habitat, but they also will also use younger stands of trees for nesting (Nelson and Wilson, 2002; Hamer and Nelson, 1995; FWS, 1997; FWS, 2004). Marbled murrelets forage in nearshore marine habitats, generally in waters less than 260 feet deep, on a variety of small fish and invertebrates (FWS, 1996a).

Northern Spotted Owl

The northern spotted owl is listed as threatened federally and in Oregon, and as endangered in Washington. The northern spotted owl is a forest bird that inhabits old-growth coniferous and mixed conifer-hardwood forests from British Columbia through northern California. Suitable habitats for spotted owls provide elements necessary for nesting, roosting, foraging, and dispersal. Characteristics of nesting and roosting habitat in western Oregon and Washington generally include forests dominated by Douglas-fir and western hemlock with large (more than 30 inches diameter at breast height) overstory trees. Canopies exhibit a moderate to high canopy closure (60 to 80 percent), and are multi-layered with multiple tree species (FWS, 1992a). In addition, trees with various structural deformities (cavities, broken tops, mistletoe infections) and large snags are also characteristics of northern spotted owl habitat, as well as accumulated fallen trees and debris on the forest floor (FWS, 1992a). Most nest and roost sites are within forest stands with trees that are often older than 200 years, but spotted owls also utilize mature forests 100 to 200 years old. Foraging and dispersal habitats may be in younger, more open and fragmented forests than those associated with nesting and roosting (FWS, 1992a).

Short-tailed Albatross

The short-tailed albatross is listed as endangered both federally and by the State of Oregon. Short-tailed albatross are oceanic birds that occur throughout most of the North Pacific Ocean and are often found close to the Pacific Coast of the United States (FWS, 2006h). The short-tailed albatross generally breeds in the South Pacific, where it nests on the ground on small oceanic islands, favoring volcanic ash slopes with sparse vegetation and formerly level open areas adjacent to tall clumps of the grass *Miscanthus sinensis* (NatureServe, 2006). Most of the world's breeding short-tailed albatross nest on Torishima Island in the Tsubamezaki colony from late October through early November. There are no breeding populations of short-tailed albatross in the United States, but attempted nesting has been regularly observed on Midway Atoll in the northwestern Hawaiian Islands (FWS, 2006h). Short-tailed albatross forage at sea, but specific geographic and seasonal distribution patterns within the marine range are not well understood. The short-tailed albatross forages at the water surface on squid, fish, eggs of flying fish, shrimp, and other crustaceans (FWS, 2006h). Short-tailed albatross are also known to follow ships and forage on scraps and other refuse (NatureServe, 2006).

Streaked Horned Lark

The streaked horned lark is a candidate for listing federally and in the State of Washington. The streaked horned lark is a rare subspecies of the horned lark that breeds and winters in Oregon and Washington. Historically, many streaked horned larks bred and over-wintered in Oregon (Gabrielson and Jewett, 1940); however, the Washington population was largely migratory (Bowles, 1900; Rogers, 1999; 2000). Currently, flocks tend to arrive in the later half of February, and most leave by mid- to late-August (Bowles, 1900; Rogers, 1999; 2000). Surveys conducted in the winter of 2003 – 2004 and 2004 – 2005 indicate that, as suggested by Rogers (2000), most streaked horned larks winter along the lower Columbia River and in western Oregon (Pearson and Hopey, 2005; Pearson et al., 2005). In 2005, Pearson and Hopey found that there are two peaks in clutch initiation: the first taking place in April through early May or late May through early June, and the second taking place in late June through early July as a result of nesting failure in the first clutch.

This species is associated with bare ground or sparsely vegetated habitats. Along the lower Columbia River, streaked horned larks nest between late March and June in sparsely vegetated, expanses of sand adjacent to the river, or in areas dominated by grasses and forbs with few or no trees or shrubs (Pearson and Hopey, 2005). Streaked horned lark nests are built in shallow depressions in the open or near grassy clumps (FWS, 2006i). Foraging for weed seeds and insects occurs in sparsely vegetated dunes, beaches, and dredge spoils, as well as intertidal areas (FWS, 2006i; Pearson and Hopey, personal observation).

Western Snowy Plover

The western snowy plover is federally listed as threatened within 50 miles of the Pacific Coast. In addition, the western snowy plover is listed in the State of Oregon as threatened and by the State of Washington as endangered. The Pacific Coast population of western snowy plovers occurs from southern Washington to southern Baja California, Mexico (FWS, 2006j). This species nests beside or near tidal waters on barren to sparsely vegetated sand beaches, dry salt flats in lagoons, dredge spoils deposited on beach or dune habitat, levees and flats at salt-evaporation ponds, and river bars (FWS, 2006j). Plovers lay their eggs in shallow depressions in sandy or salty areas with sparse vegetation between early March and late September (FWS, 2006k). Western snowy plovers forage primarily on invertebrates in the wet sand and among surf-cast kelp within the intertidal zone; in dry, sandy areas above the high tide; on salt pans; on spoil sites; and along the edges of salt marshes, salt ponds, and lagoons (FWS, 2006k).

Eight main nesting areas currently occur along Oregon's coast (FWS, 2006l). The northernmost of these sites is near the central coastal community of Florence, which is about 155 miles south of the mouth of the Columbia River. This species historically occurred within the coastal areas of the lower Columbia River, but plovers have not been documented in this area since 1985 (69 Federal Register 75617). In addition, there is no evidence that indicates the western snowy plover occurs or has occurred upstream of the mouth of the Columbia River (Pacific Coast Joint Venture, 1994).

Oregon Silverspot Butterfly

The Oregon silverspot butterfly is listed as threatened federally and as endangered by the State of Washington. The range of the Oregon silverspot butterfly is restricted to coastal areas of California, Oregon, and Washington, where it occurs in three types of grassland habitat, including coastal salt spray meadows, stabilized dunes, and mountain meadows (Washington State Department of Transportation (WDOT), 2006; FWS, 2005c). The Oregon silverspot butterfly requires the early blue violet (*Violet adunca*) as a host plant to complete its development. Females oviposit their eggs near the violet in late August and early September (FWS, 2006m). As an adult, the Oregon silverspot generally moves out of the meadows and into the fringes of conifers or brush where there is shelter for more efficient heat conservation and nectaring flights. Where such sheltered conditions exist, the adults will use various nectar sources, including California aster (*Aster chilensis*), yarrow (*Achillea millefolium*), Indian thistle (*Cirsium edule*), false dandelion (*Hypochaeris radicata*), and tansy ragwort (*Senecio jacobaea*) (FWS, 2006m).

Kincaid's Lupine

Kincaid's lupine is listed as threatened federally and by the states of Oregon and Washington. Kincaid's lupine is the primary host plant for the federally endangered Fender's blue butterfly; the plant is used by Fender's blue butterfly for egg-laying and as a larval food source (FWS, 2005b).

Kincaid's lupine is a low-growing plant that is unable to survive prolonged periods of shade. Loss of prairie habitat has made the ecosystem supporting Kincaid's lupine one of the most endangered in the United States (Noss et al., 1995). The few remnant patches of prairie habitat in Oregon and Washington are threatened to varying degrees by the spread of invasive grasses and shrubs as well as by the succession of prairie to forest (FWS, 2005a). This species is found mainly in the Willamette Valley and south into Douglas County, Oregon, where it occupies both wet and upland prairie habitats and open oak savannas (WDNR and BLM, 1997; FWS, 2005b).

Nelson's Checker-mallow

Nelson's checker-mallow is listed as threatened federally and by the State of Oregon, and is listed as endangered in Washington. There are two Nelson's checker-mallow DPSs (northern Coast Range and Willamette Valley). The Willamette Valley DPS also includes two outlying populations occurring in Cowlitz and Lewis Counties, Washington (FWS, 1998).

The Willamette Valley DPS of Nelson's checker-mallow usually occupies open habitat such as ditches, margins of streams, roadsides, fence rows, drainage swales, native prairie remnants, and fallow fields (FWS, 1998). Most known sites have been densely colonized by invasive weeds, especially introduced forage grasses. Throughout its range, Nelson's checker-mallow habitat is threatened by reduction in native prairie and grassland habitat caused by fire suppression; the associated invasion of woody species; and because of residential, agricultural, and commercial development in otherwise suitable habitat (WDNR and BLM, 1997; FWS, 1998). The Willamette Valley population is considered extremely imperiled and at high risk of extirpation due to agricultural and urban development,

competition with invasive species, seed predation by weevils, small population sizes, and genetic isolation and lack of variation (FWS, 1998).

Water Howellia

Water howellia is listed as threatened both federally and by the state of Washington. Water howellia is an aquatic plant restricted to seasonally flooded, freshwater wetlands. These wetlands are generally small (less than 2.5 acres) and shallow (less than 3 feet deep) (FWS, 1996b). Water howellia require late summer/fall drying of the wetland for seed germination, and spring submergence for growth and subsequent blooming (FWS, 1996b). In western Washington, water howellia inhabit wetlands bordered by Oregon ash and trembling aspen and are generally located adjacent to forests dominated by Douglas-fir and Oregon white oak. Shrubs and emergent vegetation often occurring near water howellia include red-osier dogwood, snowberry, hardhack, water parsnip, bur-reed, inflated sedge, lesser spearwort, and water buttercup (FWS, 1996b; WDNR and BLM, 1997).

4.6.1.2 State Listed Threatened and Endangered Species

NorthernStar consulted with the ODFW, ORNHIC, WDFW, and WNHP to identify state-listed endangered and threatened species with the potential to occur within the proposed project area. Many state listed endangered or threatened species are also federally listed; these species were discussed previously in section 4.6.1.1. Life history information for the remaining state listed threatened or endangered species are discussed below.

Bald Eagle

The bald eagle is listed as threatened by the states of Oregon and Washington. Although the bald eagle was previously listed as threatened under the ESA, the FWS announced on June 28, 2007 that the bald eagle has recovered and would be removed from the list of threatened and endangered species effective August 8, 2007. However, the bald eagle is still federally protected under the Bald and Golden Eagle Protection Act and the Migratory Bird Treaty Act. Under both laws, the disturbance of eagles, their nests, and eggs is prohibited. On June 5, 2007, the FWS issued the Bald Eagle Management Guidelines, which clarified its regulations regarding implementation of the Bald and Golden Eagle Protection Act.

In the Pacific Northwest, bald eagles typically nest in multi-layered, uneven-aged, coniferous stands that are located within 1 mile of large bodies of water (Anthony et al., 1982). Trees are preferably large and stoutly limbed, with snags, broken tops, or rocks that provide easy access to foraging areas. Bald eagles often construct several nests within a territory and alternate between them from year to year; however, overall fidelity to a territory near a reliable food source is high (Stinson et al., 2001).

In Oregon and Washington, bald eagles may begin nest repairs in December, but courtship and pair bonding generally occur during January and February (Stinson et al., 2001). Adults begin incubating eggs by mid to late March, and young hatch near the end of April. Juveniles typically fledge during July but may remain in the nest vicinity through the end of summer (Garrett et al., 1993). Bald eagles inhabiting the Columbia River estuary forage primarily on tidal flats. Although bald eagles on the Columbia River feed primarily on fish; waterfowl, mammals, and marine invertebrates also can make up about 10 percent of this species' diet (Watson et al., 1991; Garrett et al., 1993).

Adult bald eagles in Oregon and Washington remain in their territories until early fall, when they migrate to British Columbia or southeastern Alaska for about 6 weeks to forage on early salmon runs. Fledglings and juvenile eagles also migrate north during this time, but will remain in British Columbia or

Alaska for several months before returning. During this time, southern migrants will occupy rivers in Oregon and Washington for several weeks before continuing north on their migration.

Bald eagles may roost communally in the winter, with three or more eagles perching for consecutive nights in the same trees (Watson and Rodrick, 2001). Communal roosts tend to be located near a rich food resource (i.e., runs of anadromous fish, high concentrations of waterfowl) and in forest stands that are uneven-aged and have at least a remnant of the old-growth forest component (FWS, 1986). Roosts tend to have more favorable microclimates and protection from inclement weather than surrounding areas and thereby facilitate energy conservation. Areas free of disturbance also are an important feature of bald eagle wintering habitat (FWS, 1986).

The greatest threats to nesting and wintering eagle populations are activities that permanently alter bald eagle habitat (e.g., removal of nest, roost, and perch trees, removal of buffers) and human activities that temporarily disturb eagles to the point of reproductive failure or reduced vigor (Watson and Rodrick, 2001). Human activities near nest sites during the breeding season can disturb eagles, leading to abandonment and reduced reproductive success. Disturbances to feeding eagles, particularly during the winter months, can cause the birds to expend more energy, which increases their susceptibility to disease and poor health (Stalmaster, 1987).

Western Pond Turtle

The western pond turtle is listed as endangered in the State of Washington and is classified as sensitive-critical in the State of Oregon. The current range of the western pond turtle extends from Puget Sound in Washington, south to Baja California (Hays et al., 1999). This species of turtle is highly aquatic and occurs in streams, ponds, lakes, and permanent and seasonal wetlands during most of the year. Although western pond turtles spend most of their lives in water, they require terrestrial habitats for nesting. In addition, pond turtles often over-winter on land and may spend portions of the warmest months in aestivation (an inactive state to avoid drought conditions) (Hays et al., 1999). Pond turtles are generally wary, initiating escape behavior when a perceived threat is 330 feet or more distant; however, they may be seen basking on emergent or floating vegetation, logs, rocks, and occasionally mud or sand banks (Hays et al., 1999). Western pond turtles generally nest within 330 feet of water, but may occasionally nest up to 1,300 feet from the nearest waterbody. The western pond turtle is an omnivore and a scavenger, foraging primarily on insects, including the larvae of caddisflies, dragonflies, and nymphs (PacificBio, 2006).

Gray Whale

The eastern North Pacific stock of gray whale was the target of intense whaling between the 1850s and early 1900s, but has increased to about 26,600 individuals as of 1999, largely due to protection from commercial whaling. The eastern North Pacific gray whale represents one of the ESA's success stories. The gray whale was listed as endangered throughout its range on June 2, 1970, and was officially considered recovered and delisted on June 16, 1994. The gray whale is still listed as endangered in the State of Oregon.

Gray whales make the longest migration of any whale, traveling 4,600 to 6,200 miles semi-annually between their summer feeding grounds and winter breeding grounds. Gray whales generally travel within 2 miles of the shoreline over most of their migration route, unless crossing mouths of rivers and straits (Dohl et al., 1983; Braham, 1984). Most of the Eastern North Pacific stock spends the summer feeding in the northern Bering and Chukchi Seas. However, gray whales have been reported feeding in the summer in waters off of Southeast Alaska, British Columbia, Washington, Oregon, and California. Each fall, the whales generally begin their migration between November and December south along the

coast of North America from Alaska to Baja California, Mexico. The eastern North Pacific stock winters mainly along the west coast of Baja California, using certain shallow, nearly landlocked lagoons and bays. The northbound migration generally begins in mid-February and continues through May, with cows and newborn calves migrating northward primarily between March and June along the west coast of the United States.

Subsistence hunters in Alaska and Russia have traditionally harvested whales from the eastern North Pacific stock; between 1996 and 2000, an average of 97 whales per year were taken. The nearshore migration route used by gray whales makes ship strikes another potential source of mortality; between 1996 and 2000, six serious injuries or mortalities of gray whales caused by ship strikes were documented. Gray whales entangled in fishing gear have reportedly been found swimming, floating, or stranded along the Pacific Coast of the United States and British Columbia, and during the 5-year period from 1996 to 2000, an estimated five to six gray whales died per year as a result of interactions with commercial fishing gear. Gray whales are also subjected to the effects of coastal development, pollution, military activities, exploration and development of oil and gas resources, and the whale watching industry.

In 1999 and 2000, a large number of gray whale strandings (273 in 1999 and 355 in 2000) occurred along the west coast of North America between Baja California, Mexico and the Bering Sea. This was compared to an average of 38 gray whale strandings per year for the previous 4 years and only 21 strandings in 2001. While the direct cause is unknown, a variety of anthropomorphic events (e.g., chemical contamination, fishery interactions and ship strikes) are hypothesized to have played a role. Other projected theories include starvation, natural toxins, and disease.

Western Wahoo

Western wahoo is listed as threatened in the State of Washington and grows in shaded, moist draws and ravines west of the Cascades (WNHP, 2007). Western wahoo generally prefers forested areas, but is sometimes found in grassy areas with some trees. Commonly associated species include Oregon white oak (*Quercus garryana*), Douglas-fir, snowberry (*Symphoricarpos albus*), Pacific blackberry (*Rubus ursinus*), western hemlock (*Tsuga heterophylla*), swordfern, and Sitka spruce. This species is generally found on fine sandy loam, silty loam, and silty clay loam soils, and it flowers from May to June (WNHP, 2003).

4.6.1.3 Other Special Status Species

Sensitive Species

In addition to the species listed under the ESA or by the States of Oregon and Washington, seven species that are candidates for listing as endangered or threatened or species of special concern have been identified by state agencies as having the potential to occur in the vicinity of the proposed project. In addition, the NMFS and ODFW expressed concerns regarding several sensitive species, including the coastal cutthroat trout, red -legged frog, tailed frog, western painted turtle, American peregrine falcon, and olive-sided flycatcher. The life histories of these sensitive species are discussed below.

Coastal Cutthroat Trout

The coastal cutthroat trout is currently listed in Oregon as a critically sensitive species. Habitat requirements vary depending on the life history traits of individual populations. Unlike other anadromous salmonids, sea-run forms of coastal cutthroat trout do not over-winter in the ocean and rarely make extended migrations across large bodies of water (64 Federal Register 16397). Migrations are normally within 6 miles of land, but have been detected up to 30 miles offshore (Giger, 1972; Sumner, 1972; Jones,

1976; Percy, 1997; Johnston, 1982). Coastal cutthroat trout may migrate to sea in late spring/early summer at 2 to 3 years of age, and return to freshwater in late autumn/early winter; however, some migrate entirely within a freshwater environment (British Columbia Ministry of Environment, Environmental Stewardship Division, 2007; FWS, 2007a). In the Pacific Northwest, coastal cutthroat trout spawn in tributaries of small watersheds and in small tributaries of larger watersheds between summer and winter. Young cutthroat trout emerge from the gravel between March and June, depending on location and timing of spawning, with a peak in April (Trotter, 1997).

In particular, anadromous coastal cutthroat trout of Oregon typically spawn in the lower Columbia River tributaries that are free of barriers to upstream movement, and later migrate to estuarine or marine water to feed (Johnson et al., 1999). Studies done on anadromous cutthroat trout in the lower Columbia River streams have shown over a 90 percent decline in both wild and hatchery fish in the last decade (ODFW, 1997). Potential factors believed to be contributing to this decline include: genetics, fisheries, reduction in nearshore productivity, and reduction of stream and estuary habitat (ODFW, 1997).

Eulachon

Eulachon (Columbia River smelt) are a candidate for listing in the State of Washington. From December to April, eulachon migrate from the ocean to upriver spawning areas in the mainstem Columbia and Cowlitz Rivers and occasionally into the Lewis, Kalama, and Sandy Rivers. Like salmonids, both male and female adults die after spawning. Eulachon are broadcast spawners and females release from 20,000 to 60,000 eggs. The eggs are sticky and settle to the bottom where they incubate for 30 to 40 days before hatching. Larval eulachon are about 0.15 inch in size and drift with the bottom currents as they develop, ultimately entering the ocean.

Eulachon are primarily fished commercially for use as bait for both the commercial and recreational sturgeon fisheries, but they are also fished as food. Mainstem fishing is done primarily by gill net and, to a lesser extent, by otter trawl. Fishing in the tributaries is done with dip nets as regulated by the States of Oregon and Washington. Total eulachon landings for the mainstem Columbia River for 2006 were estimated at 13,221 pounds, significantly higher than 2005, which had the lowest annual landings on record (208 pounds) (WDFW, 2006b). The highly variable or possibly cyclical run size makes trends in abundance hard to interpret; however, recent ocean conditions are probably the most important factor controlling eulachon abundance, and even riverine conditions (e.g., water temperature) play a major role in determining the species' spawning distribution and abundance (NMFS, 1999).

Lampreys

The lampreys (family Petromyzonidae, stone suckers) belong to a group of fish known as Agnatha, the most primitive of all living vertebrates. Two species of lamprey are designated as sensitive species and are native to the Columbia River basin: the Pacific lamprey (*Lampetra tridentata*), and river lamprey (*L. ayresi*). The river lamprey is currently a candidate for listing as endangered or threatened in the State of Washington and the Pacific lamprey is listed vulnerable within Oregon (ODFW, 2007; WDFW, 2007). The Pacific and river lamprey are both anadromous species. On January 23, 2003, a petition was filed by 11 conservation groups to list these two species as endangered or threatened under the ESA.

Life history information is sparse for these species. Larval lampreys are referred to as ammocoetes. They spend up to 6 years burrowed in the sediment, feeding on diatoms and detritus where they transform into a juvenile stage called macrophthmia. At this stage the lampreys are silver in color, develop teeth and a sucker-like disc, and form true eyes. Physiological transformations occur that initiate migratory behaviors and enable them to tolerate sea water (Fish Passage Center, 2007). After a 2-month

transformation into adults, Pacific and river lamprey migrate into the ocean where they spend 2 to 3 years parasitizing fishes and mammals (PSMFC, 1997). Pacific lampreys enter saltwater between late winter and early spring, while river lampreys enter saltwater between May and July. Lampreys return to freshwater rivers to spawn in the spring, where they lay up to 100,000 eggs in a nest built in gravel or sandy sediments. The adults die after spawning (PSMFC, 1997; ODFW, 2002).

The freshwater habitat requirements of lamprey are similar to anadromous salmonids and include mid-gradient tributaries for spawning. Juveniles burrow into soft mud substrates and remain there for up to 6 years. Adults then move to marine environments for 2 to 3 years before returning to tributaries to spawn (Bayer and Seelye, 1999).

Columbia Torrent (seep) Salamander

The Columbia torrent (seep) salamander is a candidate for listing in the State of Washington and is listed as critical on Oregon's State Sensitive Species List. The Columbia torrent salamander lives in coastal coniferous forests at the edges of clear, cold, fast-flowing streams with rock or gravel bottoms in southwestern Washington and northern Oregon (Burke Museum of Natural History and Culture, 2006; NatureServe, 2006). They can be abundant under gravel at stream edges and in the spray zones of waterfalls. During rainy seasons, they are occasionally found on land away from streams (Burke Museum of Natural History and Culture, 2006). Breeding occurs in spring and early summer, with eggs being laid under gravel in shaded streams (NatureServe, 2006). The Columbia torrent salamander forages on aquatic and semi-aquatic invertebrates, including beetles, stoneflies, snails, flies, and amphipods. (Nussbaum et al., 1983).

Northern Red-legged Frog

The northern red-legged frog is listed as sensitive-undetermined within the Coast Range Ecosystem by the State of Oregon and occurs from southwest British Columbia to Mendocino County in northern California. This species is most common in humid forests, woodlands, grasslands, and streambanks with plant cover (California Herps, 2006). Adult frogs require riparian vegetation near deep, still, or slow-moving ponds or intermittent streams. Riparian habitats provide shelter, escape from predators, and shade to maintain cool water temperatures (Animal Diversity Web, 2007).

Reproduction in northern red-legged frogs occurs from late November to early April, ensuring water temperatures between about 43 °F and 45 °F. Breeding habitat is in permanent water sources such as lakes, ponds, reservoirs, slow streams, marshes, bogs, and swamps; however, non-breeding frogs can be highly terrestrial and are sometimes found in damp areas far from water (California Herps, 2006). The female lays egg masses ranging from 500 to 1,100 eggs in perennial waterbodies that contain extensive vegetation consisting of cattails and tules or bulrushes (Hickman and Roberts, 1995; Davidson, 1996; Jennings and Hayes, 1985). Eggs attach at a minimum depth of 18 inches and at least 2 to 3 feet from the water's edge and hatch within 6 to 14 days (Jennings et al., 1993; Davidson, 1996). As they grow, the froglets move from shallow water to knee-deep water to hide from larger predators (Jennings and Hayes, 1985; Hickman and Roberts, 1995). Males can probably reproduce after 3 years of age while females reproduce after 4 years (Jennings and Hayes, 1985). Life spans of the Northern red-legged frogs range from 12 to 15 years (Cowan, 1941).

Tailed Frog

Tailed frogs are listed as vulnerable on Oregon's State Sensitive Species List and occur in shallow, cold, clear, shaded streams typically found in permanent forests. These streams possess a bed containing rocks that adults can hide under and flat, protruding, moss-free stones that tadpoles can cling

onto with their adhesive organ (Hallock and McAllister, 2005; Getubig, 2006). Adults tend to be highly aquatic, though they have been seen to venture onto land during the night when the humidity and moisture content of the forest is high (Getubig, 2006).

Western Painted Turtle

The western painted turtle is listed as critical on Oregon's State Sensitive Species List and occurs in slow-moving shallow streams, rivers, and lakes. This species prefers soft substrates with abundant vegetation and half-submerged logs for basking (Conant and Collins, 1998). Western painted turtles forage on aquatic vegetation, insects, crayfish, and small mollusks (Conant and Collins, 1998).

Townsend's Big-eared Bat

The Townsend's big-eared bat is currently a candidate for listing as threatened or endangered in the State of Washington and is listed as critical on Oregon's State Sensitive Species List. Townsend's big-eared bat has been documented in nearly every county in Washington and is common throughout most of Oregon (WDFW, 2005). Most habitats occurring in the counties affected by the project are suitable for feeding by Townsend's big-eared bats; however, the distribution of suitable roosts influences the actual locations where they are able to feed. A variety of different roost types are required by Townsend's big-eared bats, including day, nursery, night, and winter roosts. Day roosts are used for resting and hiding during the active season and may include old buildings, silos, concrete bunkers, barns, caves, and mines (WDFW, 2005). Nursery roosts occur in similar structures as well as actively used buildings and large "rooms" in concrete dams (WDFW, 2005). Unlike day and nursery roosts, Townsend's big-eared bats use night roosts for very short periods as stopover hiding and resting places between feeding bouts, but little is known about the use of night roosts. During winter, roosts may be used for weeks to months at a time and may include caves, lava tubes, mines, and other structures. Unlike many species of bats, bridges are not considered valuable roosts for Townsend's big-eared bats (WDFW, 2005). Mating takes place between November and February, with females giving birth to a single young in late May or early June (Schmidly, 1991; Nagorsen and Brigham, 1993). Townsend's big-eared bats forage nocturnally, emerging from roosts later than many bat species to forage primarily on moths; however, they will feed on a variety of other arthropods when available (WDFW, 2005; Nagorsen and Brigham, 1993).

American Peregrine Falcon

Although the American peregrine falcon was previously listed as endangered by the State of Oregon, on April 13, 2007, the ODFW delisted the American peregrine falcon from the Oregon Threatened and Endangered Species List. American peregrine falcons occur from non-Arctic portions of Alaska and Canada south to Baja California, Central Arizona, and Mexico. This species winters chiefly in its breeding range, except that the more northern birds move south (FWS, 2006n). The American peregrine falcon nests in cliffs that tend to dominate the surrounding landscape; however, they also utilize cut riverbanks, trees, and manmade structures, including tall towers and the ledges of tall buildings (FWS, 2006n). Nests typically are situated on ledges of vertical rocky cliffs, commonly with a sheltering overhang (Palmer, 1988; Campbell et al., 1990). The diet of American peregrine falcons includes small- to medium-sized avian species, such as blue jays, flickers, meadowlarks, pigeons, starlings, shorebirds, and waterfowl (FWS, 2006n).

Lewis' Woodpecker

Lewis' woodpecker is currently a candidate for listing in the State of Washington. Although this species historically occurred throughout southwestern Washington, its distribution is currently limited to

areas east of the Cascades and is not known to occur within the project area. Lewis' woodpecker is closely associated with old-growth ponderosa pine and mature riparian cottonwood forests throughout the west (NatureServe, 2006). Suitable habitat for Lewis' woodpecker typically includes forests with an open canopy and shrubby understory, snags available for nest sites, hawking perches, and insect fauna (Bock, 1970). Breeding populations of this species are locally distributed, often occurring in colonies and in burned forests (Jewett et al., 1953; Raphael and White, 1984; Block and Brennan, 1987; and Tobalske, 1997). Lewis' woodpecker is an opportunistic feeder whose diet varies seasonally. During the spring and summer, Lewis' woodpecker primarily forages on insects including ants, bees and wasps, beetles, grasshoppers, and true bugs (Tobalske, 1997). Fruits and berries are the most frequently eaten foods in late summer and fall, and winter food sources include acorns, commercial nuts, and corn (WDFW, 2002).

Northern Goshawk

The northern goshawk is currently a candidate for listing in the State of Washington and is listed as critical on Oregon's State Sensitive Species List. The northern goshawk is widely distributed across North America and generally inhabits coniferous and mixed forests, preferring mature forests with a combination of old, tall trees with intermediate canopy coverage and small open areas within the forest for foraging during their nesting season (Pajerski, 2005; Johnsgard, 1990; Squires and Reynolds, 1997). In the western United States, this species generally nests in mature forests dominated by ponderosa pine (*Pinus ponderosa*), lodgepole pine (*Pinus contorta*), Douglas-fir, cedar, spruce, willow, and aspen (*Populus tremuloides*) (NatureServe, 2006). Typically, the nest is located near the trunk of a medium to large tree and near openings in the forest such as roads, swamps, and meadows (Pajerski, 2005). Northern goshawks breed between early April and mid-June. Mating northern goshawks begin to prepare their nests as much as 2 months before egg-laying. Northern goshawks forage on a wide variety of vertebrates and, occasionally, insects (NatureServe, 2006).

Olive-sided Flycatcher

The olive-sided flycatcher is listed as vulnerable on Oregon's State Sensitive Species List. The olive-sided flycatcher has a widespread distribution and occurs in coniferous forests, usually at mid- to high-elevations (Cornell Lab of Ornithology, 2006). Olive-sided flycatchers are most often associated with forest openings, forest edges near natural openings (e.g., meadows, bogs, canyons, rivers), human-made openings (e.g., harvest units), or open to semi-open forest stands. The olive-sided flycatcher has been recorded on both of the Breeding Bird Surveys conducted near the project area (Sauer et al., 2005).

Purple Martin

The purple martin is currently a candidate for listing in the State of Washington and is listed as critical on Oregon's State Sensitive Species List. Purple martins occur within much of the eastern United States during the summer months. In the western states, this species occurs in scattered locations along the Pacific Coast, and in the deserts and mountains of the southwest into Mexico (Cornell Lab of Ornithology, 2006). Purple martins arrive along the Pacific Coast between April and June and return to South America between August and mid-October (NatureServe, 2006). A study conducted in 1998 to determine the distribution, abundance, and nest site characteristics of purple martins in Oregon found that they were locally common along the Columbia River, in some coastal estuaries, and at the Fern Ridge Reservoir (Hovarth, 1999). Habitat chosen for nesting sites varied substantially and included open water, grassy fields, recent clearcuts, and burns with brush and young trees. However, characteristics common to nesting sites included a distance of more than 18 feet to large live trees and the presence of an unoccupied cavity (Hovarth, 1999). Purple martins forage on a variety of invertebrates, including ants, wasps, beetles, grasshoppers, and dragonflies (NatureServe, 2006).

Marine Mammals

The MMPA established, with limited exceptions, a moratorium on the “taking” of marine mammals in waters or on lands under U.S. jurisdiction. The act further regulates, with certain exceptions, the “take” of marine mammals on the high seas by persons, vessels, or other conveyances subject to the jurisdiction of the United States. Thirty-one species of marine mammals have been recorded off the coasts of Oregon and Washington, including 6 species of baleen whales; 19 species of toothed whales, beaked whales, dolphins, and porpoises; 5 species of pinnipeds (seals and sea lions); and the sea otter (Caretta et al., 2007; Angliss and Outlaw, 2008). Of these, five species of baleen whales, two species of toothed whales, and one pinniped are either state- or federally listed and are discussed in sections 4.6.1.1 and 4.6.1.2.

Off the coasts of Oregon and Washington, 11 whales (minke, short-finned pilot, Baird’s beaked, Cuvier’s beaked, pygmy sperm, dwarf sperm whales, and 6 species of mesoplodont beaked whales), 4 dolphins (Pacific white-sided, Risso’s, short-beaked common, and northern right whale dolphins), and 2 porpoises (harbor and Dall’s porpoises) are all known to occur (Caretta et al., 2007; Angliss and Outlaw, 2008). However, the occurrence of these species would generally be limited to marine portions of the waterway.

In addition, California sea lions, Pacific harbor seals, Northern elephant seals, Northern fur seals, and sea otters occur off the coasts of Washington and/or Oregon. Although Northern fur seals and Northern elephant seals are occasionally present in this area, they do not occur in great numbers or for very long (NMFS, 2007b). The extent of Northern fur seals, and Northern elephant seals, presence in nearshore marine areas adjacent to the Columbia River is unknown (NMFS, 2008b). Similarly, the occurrence of the sea otter is limited to waters off the coast of Washington from Destruction Island (near the Hoh River) north to Neah Bay (FWS, 1995). Alternatively, large numbers of California sea lions and Pacific harbor seals can be found utilizing haulout (or resting) sites along the lower Columbia River (locations shown on maps in Appendix C). These species are described below.

California Sea Lions

California sea lions are found from southern Mexico to southeast Alaska. The United States stock is defined geographically for management purposes and is described as being comprised of animals that breed in the waters of the U.S. The current population estimate for the United States stock of California sea lions is 238,000 (Caretta et al., 2007) and has now reached carrying capacity.

California sea lions generally occur in the lower Columbia River during much of the year, except between mid-June and August when most animals return to breeding rookeries in southern California. However, peak numbers occur during the migration periods in May and September (Scordino, 2006). Recent surveys conducted by the WDFW documented 1,500 California sea lions near the mouth of the Columbia River in 2006 (WDFW, 2007; Jeffries, 2008). Females are rarely observed north of the California-Oregon border; therefore, California sea lions in the Pacific Northwest are sub-adult or adult males (NMFS, 2008b).

The breeding range of California sea lions in the United States is centered on the California Channel Islands but pupping has been reported farther north on the Farallon Islands and at Año Nuevo, California (Keith et al., 1984). Mature males (over 8 years) defend breeding territories on rookeries between May and August. Females return to the rookeries to give birth and most pups are born in June. Males breed with females that come into estrus in their territory. Most males are unsuccessful at establishing breeding territory on the rookeries due to heavy competition between dominant animals and retreat to the sea or to nearby “bachelor” beaches to await breeding opportunities (Heath, 2002)

California sea lions feed on a variety of fish and cephalopods (squid, octopus) based upon season, location, and prey availability. In Oregon coastal rivers, California sea lions are known to eat salmonids and lamprey along with other non-salmonid fish (Roffe and Mate, 1984). Based on analysis of intestinal samples, the California sea lion diet in the Columbia River estuary includes smelt, salmonids, rockfish, lamprey, and herring (Brown et al., 1995).

Pacific Harbor Seals

Pacific harbor seals inhabit coastal and estuarine waters and shoreline areas from Baja California to western Alaska. The Oregon/Washington Coastal stock of harbor seal is one of three management stocks for this species along the Pacific coast of the continental United States. The range of the Oregon/Washington stock, defined geographically for management purposes, extends from the California/Oregon border north to the Strait of Juan de Fuca at Cape Flattery, Washington.

Pacific harbor seals are present throughout the year at the mouth of the Columbia River. Several stocks of Pacific harbor seals occur in waters along the Pacific Coast. The Oregon/Washington coastal stock is estimated to contain about 25,000 animals (NMFS, 2007b).

Numerous harbor seal haulout sites are found on the intertidal mudflats and sandbars in the lower Columbia River estuary including nursery areas in Cathlamet Bay near Astoria (Jeffries et al. 2000; NMFS, 2008b). Harbor seals generally are non-migratory but local movements are associated with factors such as tides, weather, season, prey availability, and reproduction (Scheffer and Slipp, 1944; Bigg, 1969, 1981). Along the coasts of Oregon and Washington females give birth to pups at haulout sites between April and mid-July (Huber et al., 2001). Females breed within weeks of giving birth and breeding activity takes place in the water (NMFS, 2008c).

Although harbor seals are present year-round in the Columbia River estuary, they do exhibit seasonal movements and their numbers within the Columbia River upstream of the South Jetty increase from January to April and then decrease from May through August as the harbor seals move to adjacent bays (e.g., Netarts Bay, Tillamook Bay, Willapa Bay, and Grays Harbor) during the pupping season (Jeffries, 2008). During a typical day in May, approximately 3,000 Pacific harbor seals can be observed resting on haulout sites in the Columbia River estuary (NMFS, 2008b), but very few, if any, may be upstream of the South Jetty area.

The diet of harbor seals in the lower Columbia River is seasonally variable and diverse. In the winter, smelt are predominant; at other times of year, the diet includes anchovy, Pacific herring, salmonids, staghorn sculpin, starry flounder, and lamprey (Riemer and Brown, 1997). Harbor seals forage at varying distances from their haulouts depending on the frequency and quantity of prey encountered. The foraging home-range for harbor seals is unstudied in the Columbia River estuary. However, several studies have taken place in other areas of the Pacific (e.g., Alaska and California). For example, despite occasional long-distance movements in excess of 124 miles, harbor seals in both the Pacific and Atlantic Oceans rarely forage more than 31 miles from haul-out sites (Lowry et al., 2001). However, harbor seals in San Francisco Bay were found to have a foraging home range of only 3 miles from their primary haulout (Grigg et al., 2001).

Migratory Bird Treaty Act

The Columbia River estuary is one of the most important sites on the Pacific Flyway for migratory birds, with more than 300 species occurring in the area throughout the year (Lower Columbia River Estuary Partnership, 2007a). Peak counts in the estuary during migration have been almost 150,000 birds (Lower Columbia River Estuary Partnership, 1999). The Migratory Bird Treaty Act implements

various treaties and conventions for the protection of migratory birds. Under this act, taking, killing, or possessing migratory birds (including any part, nest, or egg) is unlawful.

4.6.2 Impacts and Mitigation

4.6.2.1 Waterway for LNG Marine Traffic

Federally Listed Species

Fish

Lower Columbia River Chinook Salmon ESU

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult, smolt, and juvenile life stages of the Lower Columbia River Chinook salmon ESU. The marine portion of the waterway provides habitat for adult salmon throughout the year. Within the lower Columbia River, migrating spring- and fall-run adults occur between March and June and August and October, respectively. Spring-run out-migrating smolts occur during their second spring/summer, and fall-run out-migrating smolts occur primarily as sub-yearlings from April through June (NMFS, 2005c). In addition, juvenile Chinook salmon rear throughout the year in nearshore habitat of the Columbia River mainstem, lower Columbia River islands, and the accessible low gradient reaches of Columbia River floodplain sloughs.

Critical Habitat – The Lower Columbia River Chinook salmon ESU has designated critical habitat (rearing and migratory corridor PCEs) within the lower Columbia River mainstem. Chinook salmon migrate through the Columbia River estuary en route to their spawning grounds upstream. In addition, critical habitat for rearing has been designated within nearshore habitats of the Columbia River mainstem, Columbia River islands, and the accessible low gradient reaches of Columbia River floodplain sloughs (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation.

Upper Columbia River Spring-run Chinook Salmon ESU

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult and smolt life stages of the Upper Columbia River Spring-run Chinook salmon ESU. The marine portion of the waterway provides habitat for adult salmon throughout the year. Within the lower Columbia River, spawning adults migrate upstream to their spawning grounds between March and June and smolts out-migrate between May and June (NMFS, 2005c). In addition, juveniles spend approximately 1 year rearing in freshwater before passing through the lower Columbia River between May and June (NMFS, 2005c). The Upper Columbia River Spring-run Chinook salmon ESU does not have spawning or rearing habitat along the waterway.

Critical Habitat – The Columbia River is designated as critical habitat (rearing and migratory corridor PCEs) for the Upper Columbia River Spring-run Chinook salmon ESU. However, as described above, no rearing occurs along the portion of the lower Columbia River affected by LNG carrier transit (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation.

Upper Willamette River Chinook Salmon ESU

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult, smolt, and juvenile life stages of the Upper Willamette River Chinook salmon ESU. The marine portion of the waterway provides habitat for adult salmon throughout the year. Within the lower Columbia River, spawning adults migrate upstream to their spawning grounds primarily between April and May, with a peak in mid-May, but have also been known to occur as early as February (NMFS, 2005c). According to the NMFS (2005c), out-migration has been found to occur in recently emerged juveniles in the winter through early spring, in sub-yearlings in the fall through early winter, and as yearlings in the late winter through spring. In addition, juvenile Upper Willamette River Chinook salmon rear throughout the year in nearshore habitat of the Columbia River mainstem, lower Columbia River islands, and the accessible low gradient reaches of Columbia River floodplain sloughs.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Upper Willamette River Chinook salmon ESU (70 Federal Register 52630 – 52858). The lateral extent of critical habitat for each designated stream reach is defined as the width of the stream channel as defined by its bankfull elevation.

Snake River Spring/Summer-run Chinook Salmon ESU

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult and smolt life stages of the Snake River Spring/Summer-run Chinook salmon ESU. The marine portion of the waterway provides habitat for adult salmon throughout the year. Within the lower Columbia River, spawning adults migrate upstream to their spawning grounds between January and May (COE, 1973). Out-migrating smolts pass through the lower Columbia River during their second spring/summer (Bell Fisheries Handbook, 1973). The Snake River Spring/Summer-run Chinook salmon ESU does not have spawning or rearing habitat along the waterway.

Critical Habitat – The Columbia River is designated critical habitat (migratory corridor PCE) for the Snake River Spring/Summer-run Chinook salmon ESU (58 Federal Register 68543 – 68554). Adjacent riparian zones are included in the designation, defined as those areas within 300 feet of the normal line of highwater of a stream channel.

Snake River Fall-run Chinook Salmon ESU

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult, smolt, and juvenile life stages of the Snake River Fall-run Chinook salmon ESU. The marine portion of the waterway provides habitat for adult salmon throughout the year. Within the lower Columbia River, spawning adults migrate upstream to their spawning grounds between August and December and out-migrating sub-yearling smolts pass through the lower Columbia River between April and June (Bell Fisheries Handbook, 1973). In addition, juveniles spend up to 1 year rearing in nearshore habitat of the Columbia River mainstem, lower Columbia River islands, and the accessible low gradient reaches of Columbia River floodplain sloughs (Bell Fisheries Handbook, 1973).

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Snake River Fall-run Chinook salmon ESU (58 Federal Register 68543 – 68554). Adjacent riparian zones are included in the designation, defined as those areas within 300 feet of the normal line of highwater of a stream channel.

Columbia River Chum Salmon ESU

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for all life stages of the Columbia River chum salmon ESU. The marine portion of the waterway provides habitat for adult salmon throughout the year. Within the lower Columbia River, migrating adults and spawning occur between mid-October and December (Ehlke and Keller, 2003; NMFS, 2005c). Out-migrating smolts are present between March and May, with a peak in mid-March/early April (NMFS, 2005c). Juvenile chum salmon generally migrate directly to estuaries upon hatching; however, occasionally juveniles rear in the waters of the lower Columbia River and its tributaries between December and May (NMFS, 2005c).

Critical Habitat – The Columbia River is designated as critical habitat (rearing, migratory corridor, and spawning PCEs) for the Columbia River chum salmon ESU (70 Federal Register 52630 – 52858). As described above, adult chum salmon migrate through and spawn in the lower Columbia River. In addition, critical habitat for juvenile rearing has been designated within nearshore habitats of the Columbia River mainstem. The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation.

Lower Columbia River Coho Salmon ESU

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult, smolt, and juvenile life stages of the Lower Columbia River Coho Salmon ESU. The marine portion of the waterway provides habitat for adult salmon throughout the year. Within the lower Columbia River, adults migrate upstream to their spawning grounds between late August and early February, peaking in October; sub-yearling smolts out-migrate through the lower Columbia River between March and July; and juveniles rear throughout the year in nearshore habitat of the Columbia River mainstem, lower Columbia River islands, and the accessible low gradient reaches of Columbia River floodplain sloughs.

Critical Habitat – Critical habitat has not been designated for the Lower Columbia River coho salmon ESU.

Snake River Sockeye Salmon ESU

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult and smolt life stages of the Snake River sockeye salmon ESU. The marine portion of the waterway provides habitat for adult salmon throughout the year. Within the lower Columbia River, spawning adults are known to migrate upstream in two different runs to their spawning grounds. The first occurs as an early run between late July and early August, and the second occurs as a late run from September to October (Bell Fisheries Handbook, 1973). Out-migrating yearling smolts pass through the lower Columbia River between April and June (Bell Fisheries Handbook, 1973). The Snake River sockeye salmon ESU does not have spawning or rearing habitat along the waterway.

Critical Habitat – The Columbia River is designated critical habitat (migratory corridor PCE) for the Snake River sockeye salmon ESU (58 Federal Register 68543 – 68554). Critical habitat includes the adjacent riparian zone defined as those areas within 300 feet of the normal line of high water of a stream channel.

Lower Columbia River Steelhead DPS

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult, smolt, and juvenile life stages of the Lower Columbia River steelhead DPS. The marine portion of the waterway provides habitat for adult steelhead throughout the year. The lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity. Out-migrating smolts pass through the lower Columbia River between March and June with peaks in April or May (NMFS, 2005c). In addition, juveniles rear throughout the year in nearshore habitat of the Columbia River mainstem, lower Columbia River islands, and the accessible low gradient reaches of Columbia River floodplain sloughs.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Lower Columbia River steelhead DPS (70 Federal Register 52630 – 52858). The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Middle Columbia River Steelhead DPS

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult and smolt life stages of the Middle Columbia River steelhead DPS. The marine portion of the waterway provides habitat for adult steelhead throughout the year. The lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity. Out-migrating smolts pass through the lower Columbia River between March and June (NMFS, 2005c). The Middle Columbia River steelhead DPS does not have spawning or rearing habitat along the waterway.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Middle Columbia River steelhead DPS (70 Federal Register 52630 – 52858). The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Upper Columbia River Steelhead DPS

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult and smolt life stages of the Upper Columbia River steelhead DPS. The marine portion of the waterway provides habitat for adult steelhead throughout the year. The lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity. Out-migrating smolts pass through the lower Columbia River between March and June (Bell Fisheries Handbook, 1973). The Upper Columbia River steelhead DPS does not have spawning or rearing habitat along the waterway.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Upper Columbia River steelhead DPS (70 Federal Register 52630 – 52858). The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Upper Willamette River Steelhead DPS

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult and smolt life stages of the Upper Willamette River steelhead DPS. The marine portion of the waterway provides habitat for adult steelhead throughout the year. The lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity. Out-migrating smolts

pass through the lower Columbia River between March and July (Bell Fisheries Handbook, 1973). The Upper Willamette River steelhead DPS does not have spawning or rearing habitat along the waterway.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Upper Willamette River steelhead DPS (70 Federal Register 52630 – 52858). However, as described above, no rearing occurs along the portion of the lower Columbia River affected by LNG carrier transit. The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Snake River Basin Steelhead DPS

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for adult and smolt life stages of the Snake River Basin steelhead DPS. The marine portion of the waterway provides habitat for adult steelhead throughout the year. The lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity. Out-migrating smolts pass through the lower Columbia River between March and June (Bell Fisheries Handbook, 1973). The Snake River Basin steelhead DPS does not have spawning or rearing habitat along the waterway.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Snake River Basin steelhead DPS (70 Federal Register 52630 – 52858). However, as described above, no rearing occurs along the portion of the lower Columbia River affected by LNG carrier transit. The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

North American Green Sturgeon

Occurrence along the Waterway – The waterway for LNG marine traffic provides habitat for the adult life stage of North American green sturgeon. Green sturgeon occur within the marine portion of the waterway and in the lower reaches of the Columbia River (NOAA, 2006G; Israel et al, 2004). Within the lower Columbia River, sturgeon concentrate during the late summer and early fall (Adams et al, 2006).

Critical Habitat – Critical habitat has not been designated for the North American green sturgeon.

Impacts and Mitigation

During operation of the Bradwood Landing Project, LNG marine traffic could potentially affect federally listed fish species and/or their designated critical habitat through various activities including:

- fish strandings;
- shoreline erosion;
- ship engine cooling water appropriations and discharges;
- accidental spill or leak of hazardous materials; and
- accidental or intentional breach of an LNG carrier.

Potential impacts and mitigation from each of these factors are summarized in table 4.6.2-1. Potential impacts on aquatic resources (including salmonids and sturgeon) from LNG marine traffic are discussed in section 4.5.1.1. As noted previously, the FERC staff is currently revising its BA and EFH Assessment for the Bradwood Landing Project, which will be resubmitted to the NMFS with a request to initiate formal consultation in compliance with section 7 of the ESA and the MSA. The FERC would not allow construction of the project to proceed until after we have concluded formal consultation with the NMFS and FWS.

TABLE 4.6.2-1

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
LNG Marine Traffic					
Fish strandings ^b	Salmonids and sturgeon - Mortality of sub-yearlings.	Existing deep-draft vessel traffic on the lower Columbia River.	125 LNG carriers per year.	Avoid	<ul style="list-style-type: none"> The speed of LNG carriers on the Columbia River would be limited by the tethered tug to speeds below which most wake stranding occurs.
				Minimize	<ul style="list-style-type: none"> LNG carriers would only traverse the lower 38 miles of the Columbia River where very little wake stranding has been documented. We have recommended in section 4.5.1.1 that NorthernStar coordinate with the NMFS to determine appropriate LNG carrier speed, or other applicable measures, to avoid or minimize wake stranding impacts.
Shoreline erosion ^b	Salmonids and sturgeon - Resuspension of material in water column.	Shoreline erosion along the Columbia River is caused by river currents, wind waves, and ship wakes. Ship wakes breaking on shore can cause erosion along the shoreline and resuspend the eroded material with the water column.	125 LNG carriers per year would contribute ship wakes similar to other deep draft vessels on the lower Columbia River.	Minimize	<ul style="list-style-type: none"> The speed of LNG carriers on the Columbia River would be limited by the tethered tug, thus reducing the potential for shoreline erosion. We have recommended in section 4.5.1.1 that NorthernStar coordinate with the NMFS to determine appropriate LNG carrier speed, or other applicable measures, to avoid or minimize shoreline erosion impacts. We have recommended in section 4.1.3.3 that NorthernStar prepare a <i>Shoreline Monitoring Plan</i> for the west end of Puget Island.
Ship ballast and cooling water appropriations and discharges ^b	Salmonids and sturgeon - Entrainment, introduction and spread of exotic species, changes in water temperature. Discharge of warm water that has been treated with biocide.	NA	125 LNG carriers per year would appropriate and discharge water for engine cooling and as ballast.	Minimize	<ul style="list-style-type: none"> NorthernStar changed its original project design to provide screened water to ships at dock for cooling engines and filling ballast tanks, thus minimizing entrainment impacts on juvenile salmonids. NorthernStar would offer contract incentives for ships to retrofit in order to utilize the system.

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project				
Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a Description
Transiting of LNG marine vessels	Sea turtles, whales, and Steller sea lion - Increased noise levels, vessel strikes.	Existing vessel traffic.	125 LNG carriers per year.	<ul style="list-style-type: none"> While docked, LNG carriers that are retrofitted would recirculate ballast water through the engines for cooling after the shore-based water supply is turned off and until the ship is ready to leave the wharf to avoid additional water intake and discharging heated water within the LNG wharf and maneuvering area. We have recommended in section 4.3.2.3 that NorthernStar develop performance standards for water temperature impacts and biocide use associated with LNG carrier water intakes and discharges. We have recommended in section 4.5.2.1 that NorthernStar conduct post-installation water flow mapping through all intake screens at the LNG terminal, and develop and implement a monitoring program to assess the effects of impingement and entrainment from use of the screened water supply system on juvenile salmonids during terminal operations. We have recommended in section 4.5.2.1 that NorthernStar either require LNG carriers to be retrofitted or develop an alternative system meeting the same standard that does not require vessel retrofitting. LNG carrier operators would follow industry standard hull plating surface treatments and mandatory ballast management practices required by the Coast Guard and IMO to minimize possible introduction or spread of exotic species. LNG carriers push a considerable bow wave when underway on the open ocean, which would likely push sea turtles away from the vessel.

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
				Minimize	<ul style="list-style-type: none"> NorthernStar would minimize impacts on whales by contractually requiring that the LNG carriers travel in a defined area that would narrow to 10 nautical miles in width between 126 degrees to the marshalling area off the mouth of the Columbia River. We have recommended in section 4.6.2.1 that NorthernStar coordinate with the NMFS to determine appropriate LNG carrier speed and seasonal restrictions, or other applicable measures to avoid or minimize impacts on whales. All LNG carriers are constructed with double hulls, which increases the structural integrity of the hull system and provides protection for the cargo tanks in case of an accident. Each LNG carrier would maintain a SOPEP, which would contain measures to be implemented in the event of a spill or release. The presence of vessels involved in spill control and clean-up would discourage aquatic species from approaching the area. The risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed with appropriate safety and security measures.
Accidental spill or leak of hazardous materials	Salmonids, sturgeon, sea turtles, whales, and Steller sea lion - Direct impacts, changes in food sources, water contamination.	Existing vessel traffic.	125 LNG carriers per year.	Avoid	
				Minimize	
Accidental or intentional breach of an LNG carrier	Salmonids, sturgeon, sea turtles, whales, Steller sea lion, Columbian white-tailed deer, brown pelican, marbled murrelet, northern spotted owl, streaked horned lark, western snowy plover, Kincaid's lupine, and Nelson's checker-mallow - Mortality.	Existing vessel traffic.	125 LNG carriers per year.	Minimize	

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
In-water Construction Activities					
Dredging of the berth and maneuvering area; dredge material placement ^b	Salmonids and sturgeon - Alteration of habitat, increased suspended sediment and turbidity levels, removal of benthic organisms, resuspension of contaminated sediments, entrainment of eggs and juvenile salmonids, increased noise, and altered sediment transport and deposition rates. Steller sea lion - Displacement.	Nearshore habitat with water depths ranging from 21 to 42 feet. Designated as critical habitat for 12 species of salmonids. The Wahkiakum County Sand Pit site is similar in function to the LNG terminal site, but has been affected by previous and ongoing dredged material placement.	46 acres of habitat would be dredged to a depth of 42 feet CRD, making the area deeper and more uniform.	Avoid Minimize	<ul style="list-style-type: none"> Site location was chosen where no shallow water habitat would be dredged. Site location was chosen where only water deeper than 21 feet would be dredged. Dredging during the NMFS recommended in-water work window would minimize impacts on salmonids. NorthernStar would use BMPs to minimize sedimentation impacts from dredging, resulting in only minor, non-lethal effects. We have recommended in section 4.2.2.2 that NorthernStar prepare a plan to monitor the side slopes of the maneuvering area after dredging; the plan shall include slope protection measures, should such mitigation be necessary. We have recommended in section 4.10.2.2 that NorthernStar file a finalized dredging noise mitigation plan that would identify all measures to be implemented during dredging to reduce noise levels. NorthernStar would implement their terminal ESC Plan to minimize impacts on water quality. Following construction, shoreline would be replanted with native vegetative communities and monitored annually for 5 years. Pile driving would occur during the NMFS recommended in-water work window, minimizing impacts on salmonids. NorthernStar revised the project design to use larger than normal piles to minimize the number of piles required. Piles would be installed vertically, which allows the use of bubble curtains (caissons full of bubbles) to minimize sound pressure levels during pile driving.
Development of the river shoreline	Salmonids and sturgeon - Increased suspended sediment and turbidity levels.	The site was used as a rough saw mill until 1962. The site has most recently been used as a dredged material disposal site by the COE.	Site would be raised to 25 feet NAVD 88 and surrounded by a 5-foot perimeter berm.	Minimize	
Pile driving	Salmonids, sturgeon, Steller sea lions, Columbian white-tailed deer, and streaked horned larks - Increased sound pressure levels and noise.	NA	NA	Minimize	

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
Filling log pond	Salmonids and sturgeon - Loss of rearing habitat.	Off-channel refugia and rearing habitat. Designated as critical habitat for 12 species of salmonids.	Log pond would be filled during construction of the LNG terminal.	Avoid	<ul style="list-style-type: none"> • We have recommended in section 4.5.2.1 that NorthernStar continue to consult with the appropriate federal and state agencies to develop a revised Bubble Curtain Contingency Plan that establishes a performance standard to assess whether or not bubble curtains are adequately working. The plan would describe specific noise attenuation methods to be implemented if monitoring indicates poor noise attenuation performance. • NorthernStar would use a pile cap between the hammer and the pile during impact pile driving to further reduce underwater noise levels if monitoring indicates the bubble cushion within the caisson is not achieving the desired sound pressure reduction. • NorthernStar would use vibratory pile drivers as conditions allow to lower sound pressure levels during pile driving. • NorthernStar would monitor for Steller sea lions within the established Safety Zone and not start pile driving until any Steller sea lions have moved outside the Safety and Buffer Zones. • NorthernStar selected a previously developed industrial location to avoid impacts on less disturbed sites.
				Minimize	<ul style="list-style-type: none"> • NorthernStar would implement its <i>Fish Salvage Plan</i> to capture, record, and release as many salmonids as possible. • We have recommended in section 4.5.2.1 that during fish collection efforts, NorthernStar place nets at the outlet of the log pond that only allow emigration from the pond.

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
Placement of wharf and piles in nearshore portion of the Columbia River	Salmonids and sturgeon - Loss of rearing and migratory habitat; behavioral changes, increased predation, alterations to water quality.	Nearshore habitat, depths ranging from 20 to 40 feet. Designated as critical habitat for 12 species of salmonids.	Pilings would occupy about 0.4 acre of nearshore habitat. Current would go around pilings, changing microhabitats locally. Unloading platform would occupy a total area of about 0.5 acre; shading associated with the platform could alter the microhabitat within this area.	Minimize	<ul style="list-style-type: none"> The number of pilings would be minimized by using larger diameter piles.
HDD stream crossings	Salmonids and sturgeon - Loss of drilling mud to river (frac-out) and related water quality impacts.	Undisturbed stream-bottom habitats.	NA	Avoid	<ul style="list-style-type: none"> The HDD method is the preferred method for avoiding impacts on listed species.
Open-out stream crossings	Salmonids and sturgeon - Increased suspended sediment and turbidity levels, vegetation removal, increased water temperature, decreased LWD and the associated reduction in habitat, mass failures, streambank erosion, and physical damage.	Undisturbed stream-bottom habitats.	Flume or dam and pump methods would minimize suspended sediment and turbidity levels.	Avoid	<ul style="list-style-type: none"> NorthernStar would implement its <i>HDD Contingency Plan</i> to minimize potential impacts from a frac-out, if one were to occur. NorthernStar would use the HDD or bore method to cross all 12 waterbodies known to contain listed salmonids.
				Minimize	<ul style="list-style-type: none"> NorthernStar would implement our Procedures and its pipeline ESC Plan in Oregon and SWPPP in Washington to minimize potential impacts. NorthernStar would allow a riparian buffer at least 25 feet wide to permanently revegetate with native woody plant species across the entire right-of-way after construction is completed.

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
Habitat Modification					
Conversion of existing habitats to industrial use at the LNG terminal site	Columbian white-tailed deer - Habitat loss.	The LNG terminal site has patches of potentially suitable foraging, resting, and fawning habitat for the Columbian white-tailed deer.	Potentially suitable habitat for the Columbian white-tailed deer would be limited to riparian vegetation along the shoreline of the Columbia River; however, fencing around the facility and the infrastructure would preclude use of the site.	Avoid	<ul style="list-style-type: none"> • We have recommended in section 4.3.2.4 that NorthernStar continue to consult with the COE, NMFS, FWS, and appropriate federal agencies to finalize its <i>Waterbody and Wetland Construction and Mitigation Procedures Plan</i>. • NorthernStar selected a former industrial site to avoid preferred or more pristine habitats. • We have recommended in section 4.6.2.3 that pipeline construction activities shall not occur in potential habitat during the fawning season (between June 1 and July 15).
Power line construction	Salmonids and sturgeon - Change in water temperature, loss of LWD, sediment runoff. Columbian white-tailed deer - Habitat modification.	Forested habitat that is predominately commercially managed stands of Douglas-fir.	About 17.8 acres of forested habitat would be cleared for construction of the proposed power line. Of this, 5.0 acres would be maintained in a grassland/herbaceous cover type.	Minimize	<ul style="list-style-type: none"> • The LNG terminal site has been minimized and is smaller than existing LNG terminals. • During early project planning, NorthernStar rerouted the proposed power line to avoid impacts on old-growth forest. • PacifiCorp would implement BMPs to minimize erosion.
Hunt Creek Bridge Replacement	Salmonids and sturgeon - Erosion, displacement, acoustic shock and noise, increased suspended sediment and turbidity levels.	Existing bridge across Hunt Creek.	New pre-cast concrete bridge.	Avoid	<ul style="list-style-type: none"> • The proposed bridge would be located 2.4 feet above the 100-year floodplain and the concrete abutments would be installed above the MHHW and from the adjacent uplands to avoid impacts on Hunt Creek. • Existing wooden piles would remain in place; only the piers and piles that interfere with the new bridge would be cut.
				Minimize	<ul style="list-style-type: none"> • NorthernStar would implement its terminal ESC Plan to minimize potential impacts on Hunt Creek. • Bridge demolition and construction would occur during the ODFW recommended in-water work window for Hunt Creek.

TABLE 4.6.2-1 (cont'd)

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
Upland pipeline construction	Salmonids and sturgeon - Increased erosion resulting in increased suspended sediment and turbidity levels. Columbian white-tailed deer - Habitat modification, disruption of fawning. Kincaid's lupine, Nelson's checker-mallow - Removal.	Various.	Construction right-of-way would be replanted and allowed to fully revegetate.	Avoid	<ul style="list-style-type: none"> • Vegetative clearing during construction would be scheduled outside of the Columbian white-tailed deer fawning season.
				Minimize	<ul style="list-style-type: none"> • NorthernStar would implement our Procedures and its pipeline ESC Plan in Oregon and SWPPP in Washington to minimize potential impacts on water quality. • NorthernStar would allow a riparian buffer at least 25 feet wide to permanently revegetate with native woody plant species across the entire right-of-way after construction is completed. • We have recommended in section 4.4.2.3 that NorthernStar revise its <i>Noxious Weeds and Soil-borne Plant Disease Control Plan</i>. • We have recommended in section 4.6.2.2 that NorthernStar conduct additional botanical surveys before construction of the proposed pipeline.
Miscellaneous Construction Activities					
Water appropriation and discharge	Salmonids and sturgeon - Entrainment, impingement, reduced downstream flows, changes in water quality.	NA	Withdrawal of up to 84 million gallons of water from the Columbia River.	Minimize	<ul style="list-style-type: none"> • NorthernStar would install screens on all water intakes using NMFS and ODFW fish-screen criteria. • We have recommended in section 4.5.2.1 that NorthernStar conduct post-installation water flow mapping through all intake screens at the LNG terminal, and develop and implement a monitoring program to assess the effects of impingement and entrainment from use of the screened water supply system on juvenile salmonids.

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
Construction lighting of the LNG terminal site.	Salmonids and sturgeon, and Columbian white-tailed deer - Avoidance, predator attraction.	NA	Lighted construction area.	Minimize	<ul style="list-style-type: none"> We have recommended in section 4.5.2.1 that NorthernStar continue to consult with the FWS, NMFS and ODFW to finalize its <i>Terminal Lighting Plan</i> for construction and operation of the LNG terminal.
Blasting	Salmonids, sturgeon, and Steller sea lions – Changes in behavior, decreased perception, and damage to body tissue.	NA	Blasting at the quarry could generate noise levels of 115 dB.	Avoid	<ul style="list-style-type: none"> The estimated maximum noise exposure to salmonids and pinnipeds from blasting at the Bradwood quarry (115 dB) would be less than the noise thresholds for pinnipeds and salmonids (160dB_{rms} and 150 dB_{rms}). Therefore, adverse impacts on federally listed species as a result of blasting at the LNG terminal site are not expected.
				Minimize	<ul style="list-style-type: none"> We have included a recommendation that NorthernStar consult with the NMFS, FWS, ODFW, and other appropriate agencies when developing its Blasting Management Plan.
Accidental spills or leaks of hazardous materials	Salmonids and sturgeon - Water quality, direct and indirect effects on organisms.	NA	NA	Avoid	<ul style="list-style-type: none"> NorthernStar would prohibit liquid transfer as well as refueling of vehicles and equipment within 100 feet of waterbodies.
				Minimize	<ul style="list-style-type: none"> NorthernStar would implement our Procedures and its ESC Plans in Oregon and SWPPP in Washington to minimize the likelihood of an accidental spill or leak of hazardous materials occurring.
Collisions with vehicle or railway traffic	Columbian white-tailed deer - Increased likelihood of collisions between vehicles or trains and deer.	Current use of Clifton Road is estimated at about 50 vehicle trips per day. Railway is not currently in use.	Up to 1,500 vehicle trips per day would occur along Clifton and Bradwood roads during construction of the proposed project. Railway use is expected to be infrequent.	Minimize	<ul style="list-style-type: none"> NorthernStar would post speed limit and deer warning signs on all roads. NorthernStar would implement a training and awareness program for all personnel accessing the LNG terminal site. NorthernStar would make information available to train operators about the risk of collision and importance of protecting the Columbian white-tailed deer. NorthernStar would bus construction workers to the terminal site from a temporary parking lot southeast of the Taylorville interchange at Highway 30.

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
LNG Terminal Operation					
Stormwater runoff	Salmonids and sturgeon - Increased suspended sediment and turbidity levels.	The proposed LNG site currently consists of highly permeable soils (typical drainage is greater than 14 inches per hour).	About 6 acres at the proposed LNG terminal site would be impervious surface. The remainder would be either landscaping or loosely packed gravel overlying dredged materials. Modifications to Bradwood and Clifton Roads as well as the Hunt Creek Bridge replacement would increase the total impervious surface.	Avoid	<ul style="list-style-type: none"> We have recommended that NorthernStar develop a traffic management plan to reduce traffic impacts. Drainage basins described in NorthernStar's <i>Stormwater Management Plan</i> would contain stormwater runoff generated by a 100-year storm event. Curb extensions would discharge stormwater into small rock flow spreader structures before flowing through vegetation. NorthernStar would construct a bioswale on the west side of the bridge to increase this distance between the new bridge and Hunt Creek and provide storage necessary to promote infiltration. NorthernStar would install additional culverts and drainage ditches would be installed to improve stormwater drainage from Clifton Road.
Accidental spills or leaks of hazardous materials	Salmonids and sturgeon - Water quality, direct and indirect effects on organisms.	NA	NA	Avoid	<ul style="list-style-type: none"> Perimeter berm would contain any potential spills or leaks of hazardous materials at the LNG terminal.
Maintenance dredging ^b	Salmonids and sturgeon - Alteration of habitat, increased suspended sediment and turbidity levels, removal of benthic organisms, resuspension of contaminated sediments, entrainment of eggs and juvenile salmonids, increased noise, and alteration sediment transport and deposition rates. Steller sea lions - Displacement.	LNG carrier berth and maneuvering area would have developed benthic invertebrate communities due to influx from areas immediately upriver. Proposed dredge disposal site is similar in function to the LNG terminal site, but has been affected by previous and ongoing dredged material disposal.	Dredging would result in a depth of -42 feet CRD within the LNG carrier berth and maneuvering area.	Avoid	<ul style="list-style-type: none"> Loss of sediment for downstream habitat would be partially avoided by placing dredged material back into the river system.

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
				Minimize	<ul style="list-style-type: none"> Dredging during the NMFS recommended in-water work window would minimize impacts on salmonids. NorthernStar would use BMPs to minimize sedimentation impacts from dredging, resulting in only minor, non-lethal effects. NorthernStar would neutralize SCV discharge water as required under its NPDES permit prior to discharge to the Columbia River.
Routine discharge of condensate water from the SCVs	Salmonids and sturgeon - Increased acidity, temperature, and dissolved solids in water in the vicinity of the LNG terminal.	NA	Discharge of 160 gpm of water to the Columbia River.	Avoid	
				Minimize	<ul style="list-style-type: none"> NorthernStar would discharge SCV water using an outfall/diffuser system mounted below the water level. Measurable increases of dissolved solids would be contained within a 10-foot mixing zone. Water used for fire suppression system testing would be returned to the Columbia River essentially unchanged.
Routine discharge of condensate water from the fire suppression system	Salmonids and sturgeon - Increased water temperature.	NA	Discharge of 260,000 gallons of water per week to the Columbia River.	Avoid	
Operation of noise-producing equipment	Salmonids, sturgeon, Columbian white-tailed deer, and streaked horned larks - Increased sound pressure levels and noise.	Existing noise levels at the nearest noise sensitive areas range from about 44 to 48 L _{dn} (dBA).	Noise levels at the nearest noise sensitive areas would range from about 40 to 50 L _{dn} (dBA).	Minimize	<ul style="list-style-type: none"> To minimize noise generated during operation of the LNG terminal, NorthernStar would incorporate noise barriers or enclosures to block sound transmission from operating equipment; valves with "low-noise" trims, acoustical insulation for aboveground piping, and selection of equipment types with the least noise emissions. We have recommended in section 4.10.2.2 that NorthernStar make all reasonable efforts to ensure its predicted noise levels from the LNG terminal are not exceeded at noise sensitive areas.

TABLE 4.6.2-1 (cont'd)

Summary of Potential Impacts and Mitigation Measures for Federally Listed Species Associated with the Bradwood Landing Project

Action	Species - Potential Impact	Baseline Condition	Proposed Condition	Resolution ^a	Description
Lighting of the ship berth and unloading facilities	Salmonids, sturgeon, and Columbian white-tailed deer - Avoidance of the area, predator attraction.	NA	Lighted LNG import terminal.	Minimize	<ul style="list-style-type: none"> NorthernStar's final LNG terminal lighting design would include light reduction techniques (e.g., directed lighting, timers, motion sensors) to avoid unnecessary lighting. We have recommended in section 4.5.2.1 that NorthernStar continue to consult with the FWS, NMFS and ODFW to finalize its <i>Terminal Lighting Plan</i> for construction and operation of the LNG terminal.
Pipeline Operation					
Vegetative clearing for maintenance of the right-of-way	Salmonids and sturgeon - Change in water temperature, loss of LWD, sediment runoff. Columbian white-tailed deer - Habitat modification, disruption of fawning.	Variable	Maintenance of 50-foot-wide right-of-way in uplands.	Avoid	<ul style="list-style-type: none"> Vegetative clearing would be conducted outside of the Columbian white-tailed deer fawning season.
				Minimize	<ul style="list-style-type: none"> NorthernStar would implement our Procedures and its pipeline ESC Plan in Oregon and SWPPP in Washington to minimize potential impacts on water quality. NorthernStar would allow a riparian buffer adjacent to waterbodies at least 25 feet wide to permanently revegetate with native woody plant species across the entire right-of-way after construction is completed. NorthernStar would minimize the disturbance to upland forested communities by replanting the right-of-way in-kind with trees, with the exception of a 30-foot strip centered along the pipeline, which would be maintained as an herbaceous community. We have recommended in section 4.3.2.4 that NorthernStar continue to consult with the COE, NMFS, FWS, and appropriate federal agencies to finalize its <i>Waterbody and Wetland Construction and Mitigation Procedures Plan</i>.
^a Unavoidable impacts would be resolved through implementation of NorthernStar's final Compensatory Mitigation Plan.					
^b Potential impacts on federally listed species due to wake stranding, shoreline erosion, entrainment and impingement, and habitat modification due to dredging continues to be studied and will be discussed in additional detail in the revised BA and EFH Assessment.					

Sea Turtles

Occurrence along the Waterway

As discussed in section 4.6.1.1, although sea turtles are generally considered a warm temperate marine reptile, green, olive ridley, leatherback, and loggerhead sea turtles have been recorded off the coasts of Oregon and Washington in the last 10 years (Green et al., 1992). Most (62.5 percent) of these sightings occurred over the continental slope waters, with the remainder found over the continental shelf. Sea turtles would not likely occur within the lower Columbia River; however, they may occur in marine portions of the LNG carrier route.

Critical Habitat

Designated critical habitat for the sea turtles does not occur within the Zones of Concern associated with LNG carrier transit. Critical habitat has been designated for the green sea turtle in waters off of Puerto Rico and for the leatherback sea turtle in waters near the U.S. Virgin Islands (63 Federal Register 46693 – 46701 and 44 Federal Register 17711 – 17712, respectively). Critical habitat has not been designated for olive ridley or loggerhead sea turtles.

Impacts and Mitigation

As discussed in section 2.1, construction and operation of the Bradwood Landing Project would result in the addition of 125 vessel trips per year on the Columbia River and off the coasts of Oregon and Washington. Potential impacts on sea turtles as a result of increased vessel traffic include increases in underwater noise generated by engines, vessel-sea turtle strikes, and possible spills or leaks of hazardous materials.

Engine-noise produced by LNG carriers would result in temporary increases in underwater noise levels near the transiting ships. However, because sea turtles are mobile, it is anticipated that they would avoid areas with high noise levels during operation of the proposed project. Sea turtles could also be vulnerable to vessel strikes as a result of the proposed project. Vulnerability to collision with an LNG carrier would be greatest while sea turtles feed, swim, and rest near the surface of the water. In areas of intense ship traffic, sea turtles can experience propeller or collision injuries; however, most of these injuries are caused by small, fast moving vessels (NMFS, 2004b). In contrast, LNG carriers push a considerable bow wave when underway on the open ocean because of their design and large displacement tonnage. This wave pushes water, flotsam, and other small objects (such as sea turtles) away from the vessel. Therefore, sea turtles are not likely to be struck by LNG carriers as a result of the project.

If a sea turtle were to encounter a spill, leak, or accidental release of fuels, lubricants, or other hazardous substance from an LNG carrier, a turtle would be at risk due to impacts on respiratory system, skin, blood chemistry, and salt gland function (NMFS, 2004b). Sea turtles are susceptible to the effects of spills either by direct encounter or ingestion of contaminated prey. Fuel (e.g., diesel) used for vessel propulsion or auxiliary/emergency generators could potentially spill or leak. However, fuel on each ship is protected by the vessel's double hull. Furthermore, each LNG carrier would maintain a SOPEP which would contain measures to be implemented in the event of a petroleum release (see section 4.3.2.2). In addition, the presence of the vessels involved in spill control and clean-up would discourage sea turtles from approaching spill areas.

The potential exists for an LNG spill and associated fire during transit of the LNG carriers to the LNG terminal that could affect sea turtles present at the ocean surface at the time of the spill. As described in section 4.11.5.3, the released LNG would vaporize rapidly upon contact with the air and

water. Because LNG is not soluble in water and the LNG would completely vaporize shortly after being spilled, there would be no liquid left that could mix and/or contaminate the water. However, the greatest threat to sea turtles from an LNG spill would be thermal stress from coming into contact with the cryogenic liquid (before the LNG vaporizes) or the fire associated with the ignited vapors. Any sea turtles in the immediate vicinity of the LNG or the fire would probably experience a sudden thermal shock that would be lethal. Sea turtles in the general area of a spill would most likely detect the temperature change and avoid the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Whales

Occurrence along the Waterway

Seven species of whales potentially occur off the coasts of Oregon and Washington, including the blue, fin, humpback, North Pacific right, sei, Southern Resident killer, and sperm whales. Whales tend to feed during the summer in the northern latitudes and migrate to the tropical southern latitudes in the winter for breeding. Some whales do not migrate as far north as the rest of the population; therefore, whales can be encountered throughout the year off the coasts of Oregon and Washington.

Critical Habitat

Critical habitat has not been designated for any of the species potentially occurring along the LNG carrier route. However, designated critical habitat for the Southern Resident killer whale DPS has been designated in three specific areas: the Summer Core Area in Haro Strait and waters around the San Juan Islands; Puget Sound; and the Strait of Juan de Fuca (71 Federal Register 69054 – 69070).

Impacts and Mitigation

Construction of the Bradwood Landing Project would not result in impacts on whales. However, operation of the project would result in increased vessel traffic as LNG carriers move through the EEZ to and from the proposed LNG import terminal on the Columbia River. The Columbia River currently supports between 1,800 and 2,000 vessel trips per year. The project would increase vessel traffic into the Columbia River by an additional 125 roundtrip vessel trips, annually. The increase of 125 vessels trips per year from the Bradwood Landing Project represents a 7 percent increase over the current volume. Potential impacts on whales resulting from increased vessel traffic could include: increases in underwater noise generated by engines, vessel-whale strikes, and spills or leaks of hazardous materials.

Noise – Operation of the Bradwood Landing Project has the potential to impact whales due to periodic increases in both underwater and surface noise. This noise would be generated by ship engines as they transit to and from their port of origin (LNG export facility), through the EEZ, to and from the proposed LNG import terminal on the Columbia River.

Noise in the aquatic environment is defined as sound from an array of sources that does not convey biologically significant information. The marine environment contains many natural and anthropogenic sources of noise. Natural noise includes surf, wind, earthquakes, and biological activity. Anthropogenic sources include noise generated to locate submerged objects, measure environmental features, and conduct industrial activities. Noise can be neutral background acoustical clutter, or can impede acoustic communication or other biological functions (NMFS, 2005b).

Cargo ships are the largest component of commercial vessel traffic and also generate higher levels of low frequency noise than other vessels. Over the last few decades, vessel operation statistics indicate steady growth in vessel traffic with an increase in both the number of vessels and in the tonnage of goods shipped (Mazzuca, 2001). Along the Pacific Coast, the bulk of commercial vessel traffic is concentrated through a few major ports, including Los Angeles, Long Beach, Oakland, Seattle, and Tacoma. Noise from shipping is concentrated into the regions adjacent to these ports and their approaches (Hildebrand, 2004). For example, between 1950 and 2000, the overall increase in low-frequency noise was 16 dB (Mazzuca, 2001). During this period, the number of ships worldwide tripled (from about 30,000 to 87,000) and the gross tonnage increased by a factor of 6.5 (from about 85 to 550 million gross tons) (NRC, 2003; Hildebrand, 2004).

LNG carriers are in the category of cargo and tanker vessels, which are increasing in numbers world wide. Cargo vessels are known to emit high levels of low frequency sound (6.8 to 7.7 hertz (Hz) at 181 to 190 dB, re: 1 μ Pa) capable of traveling long distances (Richardson et al., 1995). Noise generated by LNG carriers is generally omni-directional, emitting from all sides of the vessel. Noise levels are greater on the sides of the vessel and weaker on the front and rear of the ship. The omni-directional, moving sound source may be the reason that whales do not always avoid oncoming ships and are thus struck and either injured or killed.

Whales tend to either react strongly or not at all to the noise generated by oncoming ships. These reactions often occur in response to changes in engine and propeller speed. Baleen whales generally avoid approaching vessels and exhibit a greater tendency to avoid vessels moving at higher speeds. In order to avoid an approaching vessel, baleen whales may move to an area more than 1 mile from their original location.

Vessel-whale Strikes –Whales are seasonally present predominantly where the continental shelf and the continental slope occur (Green et al., 1991). Green et al. (2001) also found that whales are not randomly distributed off the Oregon and Washington coasts: humpback whales tend to travel north and south over the continental slope and outer continental shelf during summer; sperm whales have a wider distribution, but are generally found outside the continental slope; and fin whales are primarily found over the continental slope. In addition, some species tend to concentrate in certain areas off the Oregon and Washington coasts. Numerous surveys have been conducted in the waters off of Oregon and Washington to determine whale species distribution, abundance, and habitat use patterns. In addition, data compiled by the NMFS National Marine Mammal Laboratory's POP database was used to assess whale distribution. Based on the distribution data from both the POP database and available survey data, at any point beyond the base of the continental slope, whale sightings become increasingly rare and not as likely as a sighting along either the slope or shelf. The exception to this would be sperm and sei whales, which are known to have a more oceanic (deeper depth) distribution than other whale species. Therefore, collisions between LNG carriers and whales are less likely in the open ocean over the abyssal plain or ocean floor than they are along the continental shelf and slope. Figure 4.6.1-1 shows the confirmed whale sightings off the coasts of Oregon and Washington in relation to the continental slope and shelf.

The ship strike database indicates that large and fast moving vessels (greater than 12 knots) are most typically associated with whale strikes. Some species of whales have been found to exhibit behaviors that increase their susceptibility to collision when approached by vessels. These behaviors include startle responses, more erratic surface movements, reduced surface time, fewer blows per surfacing, shorter intervals between successive blows, and increased frequency of dives without raised flukes (Whitehead et al., 1990; Cawthorn, 1992; Gordon et al., 1992).

When in the open ocean, LNG carriers are expected to travel at approximately 20 knots. Vessels in the open ocean are not subject to any speed restrictions and generally transit along the Great Circle

Route, which is about 300 miles offshore. This open ocean area is considered outside of the project area and within the range of existing conditions because the LNG carriers would be present with all other commercial vessels in the open ocean, regardless of its specific port. However, on approach to ports, vessel traffic is concentrated over the continental shelf and slope, which is also where many whale species congregate off the coasts of Oregon and Washington, especially during the summer months.

Within the Columbia River navigation channel (CRM -3 to CRM 100) and in the marine waters approaching the entrance/exit of the navigation channel (at least out to CRM -8) the Columbia River Bar and River Pilots would determine the ship speed. The decision about proper LNG carrier speed is founded on prudent seamanship and sound marine practice and is targeted toward safe navigation and maneuvering of the vessel. The appropriate speed for given circumstances is highly dependent on the navigation channel characteristics, weather conditions, tide, type of ship, existing vessel traffic and any other maneuvering constraints. LNG carrier speeds would accordingly vary depending on current conditions, but would be limited to approximately 12 knots. This limitation is due to the escort tugboat on stern tether during transit. At present, there is no known speed restriction to reduce vessel collisions with marine mammals within the Columbia River shipping channel. However, given the nature of the entrance to the Columbia River, LNG carriers would be operating at controlled speeds such that large whales and other marine mammals should have sufficient time to avoid the carrier in this location.

Based on information provided by the NMFS, 11 vessel strikes were either reported in the region or detected by necropsy by the Northwest Marine Mammal Stranding Network between January 2002 and January 2008 (NMFS, 2007a; 2008). Strikes were observed in every month except March, April, and December; therefore, we cannot predict whether a vessel strike would be more likely during certain times of the year. Of the reported whale-vessel strikes, fin whales were encountered most frequently (six strikes), and blue, sei, humpback, sperm, and gray whales each had one strike. Jensen and Silber (2003) note that many strikes likely go undetected or unreported as they may occur in remote areas or struck whales may drift out to sea. Thus, the actual number of whale strikes is undoubtedly much greater than reported (Jensen and Silber, 2003). Using the ship trip database for the area between the Strait of Juan de Fuca and Humboldt Bay, approximately 7,931 vessel trips (including LNG carriers) occurred along the coastline in 2002 (Pacific States/British Columbia Oil Spill Task Force, 2002). Because there is no vessel traffic data for any prior or subsequent years, NorthernStar used the number of transits in 2002 as representative of the volume of traffic in this area. This resulted in a total of about 47,586 vessel trips in this region over the same time period that resulted in 11 recorded whale strikes. Based on the available information presented above, statistically, every 7,931 vessel trips would result in a reported fin whale strike and every 47,586 vessel trips would result in a reported blue, sei, humpback, sperm, and gray whale strike. However, as noted above, the number of ship trips per whale strike is likely lower than current information suggests.

The Bradwood Landing Project would result in about 125 LNG carriers calling on the LNG terminal per year, which would result in about 250 vessel trips (to and from the terminal) per year. Based on the number of vessel trips calling on the LNG terminal annually and an estimated operating life 40 years for the LNG terminal (see section 2.9), approximately 10,000 vessel trips would occur during operation of the Bradwood Landing Project. Therefore, our analysis indicates that statistically, LNG carriers associated with the Bradwood Landing Project would strike 1.25 fin whales. The likelihood of an LNG carrier striking a blue, sei, or humpback whale would be about 20 percent.

Based on comments made by the NMFS in its May 11, 2007 letter to the FERC, NorthernStar submitted an analysis of the potential for a vessel-whale strike to occur due to operation of the Bradwood Landing Project. The information provided by NorthernStar states that the statistical likelihood of a vessel-whale strike during operation of the project (40 years) would be less than one whale. However,

based on the assumptions used in NorthernStar's analysis and on feedback received from the NMFS, we feel that the FERC staff's analysis more accurately represents the likelihood of a vessel strike.

NorthernStar would minimize impacts on whales by contractually requiring that the LNG carriers travel in a defined area that would narrow to 10 nautical miles in width between 126 degrees (west of the toe of the continental slope) to the marshalling area off the mouth of the Columbia River (see figure 4.6.1-1). Traveling at an angle that is perpendicular to the continental slope and shelf would minimize the transit through areas where whales would be most likely to occur. This route would avoid known feeding concentration areas and National Marine Sanctuaries. However, because the project would be statistically likely to strike a fin whale, additional measures are necessary to minimize potential impacts on whales. Therefore, **we recommend that:**

- **NorthernStar should coordinate with the NMFS to determine appropriate LNG carrier speed and seasonal restrictions, or other restrictions to be implemented, to avoid or minimize impacts on whales. Results of the coordination, including a discussion of restrictions to be implemented, should be filed with the Secretary, prior to commencing operation of the LNG terminal.**

As noted previously, the FERC staff is currently revising its BA and EFH Assessment for the Bradwood Landing Project, which will be resubmitted to the NMFS with a request to initiate formal consultation in compliance with section 7 of the ESA. The FERC would not allow construction of the project to proceed until we have completed formal consultation.

Spills or Leaks of Hazardous Materials – Spills, leaks, or accidental releases of fuels, lubricants, or other hazardous substances could potentially occur during operation of the proposed project. A spill, leak, or accidental release of hazardous materials to offshore waters could impact whales directly or indirectly through changes in food sources or contamination of the water. However, as discussed above under sea turtles, each vessel would maintain a SOPEP.

The potential exists for an LNG spill and associated fire during transit of the LNG carriers to the LNG terminal that could affect whales present in the area at the time of the spill. As stated in section 4.11.5.3, the released LNG would vaporize rapidly upon contact with the air and water. Because LNG is not soluble in water and the LNG would completely vaporize shortly after being spilled, there would be no liquid left that could mix with and/or contaminate the water. The greatest threat to whales from an LNG spill would be thermal stress from coming into contact with the cryogenic liquid (before the LNG vaporizes) or the fire associated with the ignited vapors. Any whales that came into direct contact with the LNG or the fire would probably experience a sudden thermal shock that could be lethal. Whales in the general area of a spill would most likely detect the temperature change and avoid the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Steller Sea Lion

Occurrence along the Waterway

Two pinniped haulouts occur along the waterway for LNG marine traffic, the South Jetty and the docks at the Astoria East Mooring Basin. The South Jetty is located near the mouth of the Columbia River and is used by hundreds of Steller sea lions every year (LCFRB, 2004). Steller sea lions have also been documented hauling out at the Astoria East Mooring Basin (Brown, 2008). Use of the haulouts is lowest in the spring and summer (during the breeding season) and increases in fall and winter when animals move to haulouts and forage on salmonids and eulachon. Recent surveys by the WDFW

documented 1,500 Steller sea lions near the mouth of the Columbia River (WDFW, 2007; Jeffries, 2008). The nearest rookery is Three Arch Rocks, which is located about 60 miles south of the mouth of the Columbia River.

Critical Habitat

Designated critical habitat for the Steller sea lion does not occur within the Zones of Concern associated with LNG carrier transit. The nearest occurrence of designated critical habitat for the Steller sea lion is at Orford Reef near Port Orford, approximately 280 miles south of the Columbia River mouth (58 Federal Register 45269 – 45285).

Impacts and Mitigation

During operation of the Bradwood Landing Project, Steller sea lions could be impacted by increased LNG marine traffic and accidental spills or leaks of hazardous materials along the LNG carrier route. To date, the various impacts on Steller sea lions from human disturbance have not been studied. Close approach by humans and boats has been shown to cause sea lions at haulouts to go into the water (NMFS, 1992). Repeated disturbance by humans could result in abandonment of the South Jetty haulout site (Kenyon, 1962). However, due to the Steller sea lions' tolerance of current large vessel traffic along the Columbia River, it is expected that an increase of about 7 percent in large vessel traffic during operation of the proposed project would not significantly increase disturbance to Steller sea lions. Similarly, the wakes from LNG carriers moving to and from the proposed LNG import terminal would not significantly increase wave heights and the potential to disturb sea lions at the South Jetty haulout site. Collisions with Steller sea lions would not be expected from the LNG marine traffic because Steller sea lions are highly maneuverable and fast swimmers and they are accustomed to ship traffic in this area. There are no known reports of collisions between Steller sea lions and vessels.

Spills, leaks, or accidental releases of fuels, lubricants, or other hazardous substances could potentially occur during operation of the proposed project. A spill, leak, or accidental release of hazardous materials could result in mortality to the Steller sea lion. However, as indicated above under the discussion of sea turtles, each vessel would maintain a SOPEP.

The potential exists for an LNG spill and associated fire during transit of the LNG carriers to the LNG terminal that could affect Steller sea lions present in the area at the time of the spill. The greatest threat to Steller sea lions occurring adjacent to the shipping route from an LNG spill would be thermal stress from coming into contact with the cryogenic liquid (before the LNG vaporizes) or the fire associated with the ignited vapors. This could be particularly damaging if the LNG spill were near the South Jetty or the Large Navigation Buoy during the fall or winter months when use of these sites as haulouts by Steller sea lions is greatest. Any sea lions that came into direct contact with the LNG or the fire would probably experience a sudden thermal shock that could be lethal. Sea lions in the general area of a spill would most likely detect the temperature change and avoid the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Columbian White-tailed Deer

Occurrence along the Waterway

Columbian white-tailed deer typically inhabit forested areas located along waterways and generally select areas that offer both food and cover (Davison, 1979; Verts and Carraway, 1998). Based

on current distribution, Columbian white-tailed deer would only occur between CRM 33 and the LNG terminal.

Critical Habitat

Critical habitat has not been designated for the Columbian white-tailed deer.

Impacts and Mitigation

During operation of the proposed project, impacts on Columbian white-tailed deer from LNG marine traffic would be limited to an accidental or intentional breach of an LNG carrier. Potential impacts on Columbian white-tailed deer from a release of LNG and associated fire include habitat modification, injury, or mortality. In the event of a collision or allision of sufficient magnitude to rupture an LNG cargo tank, it is likely that sparks or flames would ignite the flammable vapors at the spill site. In the unlikely event that ignition did not occur, an LNG spill would rapidly vaporize on water and form a potentially flammable cloud. If the flammable vapor cloud encountered an ignition source, the cloud would burn back to the spill site, rather than outward towards shoreline habitats. In the unlikely event of an LNG spill on water, ignition of the LNG vapors could contribute to a forest fire in areas where the ship route is adjacent to forested habitat. The intensity and extent of a potential forest fire and the resulting damage to Columbian white-tailed deer and its habitat would be highly dependent on a number of variables including the extent of the LNG spill, available fuel (e.g., woody material), moisture and temperature, fuel composition, wind, and topography. Nearly 11,000 acres of essential habitat (both privately owned and part of the JBHNWR) are found within the Zones of Concern, a portion of which could be affected if an accidental or intentional breach of an LNG carrier were to occur during transit. Due to the deer's limited routes of egress from islands along the LNG transit route (e.g., Tenasillahe, Crims, and Wallace Islands), it is possible that a catastrophic event involving an LNG carrier could result in adverse impacts on a subpopulation of Columbian white-tailed deer. However, as discussed in section 4.11.5.3, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Brown Pelican

Occurrence along the Waterway

The brown pelican primarily occurs in coastal habitats; they are rarely seen inland or far out at sea (FWS, 2006g). Therefore, brown pelicans occurring along the waterway would be concentrated in the area near the mouth of the Columbia River during the late spring, summer, and early fall months (FWS, 2008).

Critical Habitat

Critical habitat has not been designated for the brown pelican.

Impacts and Mitigation

During operation of the proposed project, impacts on brown pelicans from LNG marine traffic would be limited to an accidental or intentional breach of an LNG carrier. If a brown pelican were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the pelican would likely be injured, killed, or displaced from the area. The potential exists for an LNG spill and associated fire during transit of the LNG carriers to the LNG terminal that could affect brown pelicans present in the area at the time of the spill. The greatest threat to brown pelicans occurring along the waterway from an

LNG spill would be thermal stress from coming into contact with the cryogenic liquid (before the LNG vaporizes) or the fire associated with the ignited vapors. This could be particularly damaging if the LNG spill were near East Sand Island between late spring and early fall when brown pelicans concentrations are highest. Any pelicans that came into direct contact with the LNG or the fire would probably experience a sudden thermal shock that could be lethal. Brown pelicans in the general area of a spill would most likely detect the temperature change and avoid the area. However, as discussed in section 4.11.5.3, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Marbled Murrelet

Occurrence along the Waterway

Marbled murrelets may occur in old-growth forest and nearshore habitats along the LNG carrier route throughout the year. In addition, about 176 acres of designated critical habitat for the marbled murrelet occur within the Zones of Concern.

Critical Habitat

Designated critical habitat for the marbled murrelet does not occur within the Zones of Concern associated with LNG carrier transit. The closest critical habitat unit to the LNG carrier route is OR-01-a, which is about 2.5 miles southeast of the LNG terminal site near Wauna, in Clatsop County, Oregon (61 Federal Register 26255 – 26320).

Impacts and Mitigation

During operation of the proposed project, impacts on marbled murrelets from LNG marine traffic would be limited to an accidental or intentional breach of an LNG carrier. Potential impacts on the marbled murrelet and its designated critical habitat from a release of LNG and associated fire include habitat modification, injury, or mortality. In the unlikely event of an LNG spill on water, ignition of the LNG vapors could contribute to a forest fire in areas where the ship route is adjacent to marbled murrelet habitat. This could be particularly damaging if a spill were to occur during the marbled murrelet nesting season. Given the relatively high precipitation in the region, large forest fires in the area are infrequent but they can be severe when they do occur. The intensity and extent of a potential forest fire and the resulting damage to marbled murrelet habitat would be highly dependent on a number of variables including the extent of the LNG spill, available fuel (e.g., woody material), moisture and temperature, fuel composition, wind, and topography. However, as discussed in section 4.11.5.3, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Northern Spotted Owl

Occurrence along the Waterway

Northern spotted owl may occur in old-growth coniferous and mixed conifer-hardwood forests along the LNG carrier route throughout the year.

Critical Habitat

Designated critical habitat for the northern spotted owl does not occur within the Zones of Concern associated with LNG carrier transit. The closest critical habitat unit to the LNG carrier route is

WA-39 (57 Federal Register 1796 – 1838), which is located about 24.4 miles east of the pipeline interconnect with the Williams Northwest pipeline system in eastern Cowlitz County (FWS, 1992b).

Impacts and Mitigation

During operation of the proposed project, impacts on northern spotted owls from LNG marine traffic would be limited to an accidental or intentional breach of an LNG carrier. If a northern spotted owl were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the risk and impacts would be similar to those described above for the marbled murrelet.

Short-tailed Albatross

Occurrence along the Waterway

Because the short-tailed albatross is a pelagic species, this species may occur in waters off the coasts of Oregon and Washington.

Critical Habitat

Critical habitat has not been designated for the short-tailed albatross.

Impacts and Mitigation

During operation of the proposed project, impacts on short-tailed albatross from LNG carrier traffic would be limited to an accidental or intentional breach of an LNG carrier. If a short-tailed albatross were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the albatross would likely be injured, killed, or displaced from the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Streaked Horned Lark

Occurrence along the Waterway

Streaked horned lark breeding and wintering areas occur along the waterway for LNG marine traffic on five dredge spoil islands along the lower Columbia River, including Rice Island, Miller Sands, Pillar Rock Island, West Wallace Island, and an unnamed island located just upstream of Tenasillahe Island (Pearson and Altman, 2005). Although some streaked horned larks are migratory, these sites may be occupied throughout the year.

Critical Habitat

Critical habitat has not been designated for the streaked horned lark.

Impacts and Mitigation

During operation of the proposed project, impacts on streaked horned larks from LNG carrier traffic would be limited to possible increased shoreline erosion and an accidental or intentional breach of an LNG carrier. If a streaked horned lark were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the lark would likely be injured, killed, or displaced from the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is

extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Western Snowy Plover

Occurrence along the Waterway

The western snowy plover historically occurred within the coastal areas of the lower Columbia River; however, plovers have not been documented along the lower Columbia River since 1985 (69 Federal Register 75617). In addition, there is no evidence that indicates the western snowy plover occurs or has occurred upstream of the mouth of the Columbia River (Pacific Coast Joint Venture, 1994).

Critical Habitat

Designated critical habitat for the western snowy plover does not occur within the Zones of Concern associated with LNG carrier transit. The nearest designated critical habitat unit to the waterway for LNG marine traffic is WA-4, which is located about 40 miles northwest of the LNG terminal in Pacific County, Washington (64 Federal Register 68507 – 68544).

Impacts and Mitigation

During operation of the proposed project, impacts on western snowy plovers from LNG carrier traffic would be limited to an accidental or intentional breach of an LNG carrier. If a western snowy plover were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the plover would likely be injured, killed, or displaced from the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Oregon Silverspot Butterfly

Occurrence along the Waterway

Within the counties located adjacent to the LNG carrier route, the Oregon silverspot butterfly is only known to occur within the coastal dune habitat in Clatsop County, Oregon. While potential habitat may be present, Oregon silverspot butterflies are not known to occur along the LNG carrier route.

Critical Habitat

Designated critical habitat for the Oregon silverspot butterfly does not occur within the Zones of Concern associated with LNG carrier transit. The nearest designated critical habitat unit to the waterway for LNG marine traffic is located about 175 miles south of the LNG terminal in Lane County, Oregon (45 Federal Register 44935 – 44939).

Impacts and Mitigation

During operation of the proposed project, impacts on Oregon silverspot butterflies from LNG carrier traffic would be limited to an accidental or intentional breach of an LNG carrier. If an Oregon silverspot butterfly were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the butterfly would likely be injured, killed, or displaced from the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Kincaid's Lupine

Occurrence along the Waterway

While potential habitat may be present, no Kincaid's lupine plants are known to occur within the Zones of Concern along the waterway for LNG marine transit.

Critical Habitat

Critical habitat has not been designated for Kincaid's lupine. However, critical habitat was proposed for this species in 2005 (70 Federal Register 66491 – 66599). The nearest proposed critical habitat unit for this species is located in Lewis County, Washington, which is approximately 30 miles northeast of the proposed LNG terminal site.

Impacts and Mitigation

During operation of the proposed project, impacts on Kincaid's lupine from LNG carrier traffic would be limited to an accidental or intentional breach of an LNG carrier. In the unlikely event that an accidental or intentional breach of an LNG carrier resulted in a forest fire, the resulting damage to Kincaid's lupine and its habitat would be highly dependent on a number of variables including the extent of the LNG spill, available fuel (e.g., woody material), moisture and temperature, fuel composition, wind, and topography. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Nelson's Checker-mallow

Occurrence along the Waterway

While potential habitat may be present, no Nelson's checker-mallow plants are known to occur within the Zones of Concern along the waterway for LNG marine transit.

Critical Habitat

Critical habitat has not been designated for Nelson's checker-mallow.

Impacts and Mitigation

During operation of the proposed project, impacts on Nelson's checker-mallow from LNG carrier traffic would be limited to an accidental or intentional breach of an LNG carrier. The risks and impacts associated with an accidental or intentional breach of an LNG carrier on Nelson's checker-mallow would be similar to those described for Kincaid's lupine.

State Listed Threatened and Endangered Species

NorthernStar consulted with the ODFW, ORNHIC, WDFW, and WNHP to identify state listed endangered and threatened species with the potential to occur within the proposed project area. Many state listed endangered or threatened species are also federally listed; these species were discussed above (see *Waterway for LNG Marine Traffic, Federally Listed Species*). The remaining state listed threatened or endangered species are discussed below.

Gray Whale

Gray whales occur off the coasts of Oregon and Washington during their northern migration between March and June and their southern migration, beginning in November and December. Potential impacts on gray whales as a result of LNG carrier traffic associated with the Bradwood Landing Project are discussed above (see *Whales*).

Bald Eagle

Bald eagle nesting, foraging, and wintering areas occur along the waterway for LNG marine traffic in the form of mature riparian forested and upland forested habitats. Bald eagles occur along the lower Columbia River throughout the year. During operation of the proposed project, impacts on bald eagles from LNG marine traffic would be limited to an accidental or intentional breach of an LNG carrier. Potential impacts on bald eagles from a release of LNG and associated fire include habitat modification, injury, or mortality. In the unlikely event of an LNG spill on water, ignition of the LNG vapors could contribute to a forest fire in areas where the ship route is adjacent to bald eagle habitat. This could be particularly damaging if a spill were to occur during the bald eagle nesting season. Given the relatively high precipitation in the region, large forest fires in the area are infrequent but they can be severe when they do occur. The intensity and extent of a potential forest fire and the resulting damage to bald eagle habitat would be highly dependent on a number of variables including the extent of the LNG spill, available fuel (e.g., woody material), moisture and temperature, fuel composition, wind, and topography. However, as discussed in section 4.11.5.3, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Other Special Status Species

Sensitive Species

In addition to the species listed under the ESA or by the States of Oregon and Washington, five species that are candidates for listing as endangered or threatened or species of special concern have been identified by state agencies as having the potential to occur in the vicinity of the proposed project. The ODFW also expressed concerns regarding several other sensitive species, including the coastal cutthroat trout, red-legged frog, tailed frog, western painted turtle, American peregrine falcon, and olive-sided flycatcher. These sensitive species are discussed below.

Coastal Cutthroat Trout

During operation of the Bradwood Landing Project, potential impacts on coastal cutthroat trout from LNG marine traffic would be similar to those associated with aquatic species (Section 4.5.1.1).

Eulachon

During operation of the Bradwood Landing Project, potential impacts on eulachon from LNG marine traffic would be similar to those associated with aquatic species (Section 4.5.1.1).

Lampreys

During operation of the Bradwood Landing Project, potential impacts on lampreys from LNG marine traffic would be similar to those associated with aquatic species (see section 4.5.1.1).

Red-legged Frog

If a red-legged frog were to be within the Zones of Concern in the event of an accidental or intentional breach, the frog would likely be injured, killed, or displaced from the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Tailed Frog

If a tailed frog were to be within the Zones of Concern in the event of an accidental or intentional breach, the frog would likely be injured, killed, or displaced from the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

Western Painted Turtle

If a western painted turtle were to be within the Zones of Concern in the event of an accidental or intentional breach, the turtle would likely be injured, killed, or displaced from the area. However, the risk of an accidental or intentional release of LNG during transit of the LNG carriers is extremely low and can be managed by implementing the recommendations in the Coast Guard's WSR (Appendix G).

American Peregrine Falcon

American peregrine falcons may occur in cliffs, riverbanks, and trees and on the ledges of vertical structures within the Zones of Concern throughout the year (FWS, 2006n). If an American peregrine falcon were in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the risks and impacts would be similar to those described above for the bald eagle.

Northern Goshawk

If a northern goshawk were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the risks and impacts would be similar to those described above for the bald eagle.

Olive-sided Flycatcher

If an olive-sided flycatcher were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the risks and impacts would be similar to those described above for the bald eagle.

Purple Martin

If a purple martin were to be in the vicinity of an LNG carrier in the event of an accidental or intentional breach, the risks and impacts would be similar to those described above for the bald eagle.

Marine Mammals

As described in section 4.6.1.1, thirty-one species of marine mammals have been recorded off the coasts of Oregon and Washington, including 6 species of baleen whales; 19 species of toothed whales, beaked whales, dolphins, and porpoises; 5 species of pinnipeds (seals and sea lions); and the sea otter (Caretta et al., 2007; Angliss and Outlaw, 2008). Of these, five species of baleen whales, two species of

toothed whales, and one pinniped are either state- or federally listed and are discussed in sections 4.6.1.1 and 4.6.1.2.

The 22 remaining species include 11 whales, 4 dolphins, 4 pinnipeds, 2 porpoises, and the sea otter. As described in section 4.6.1.3, occurrence of whales, dolphins, and porpoises would be limited to marine portions of the waterway. Northern fur seals and Northern elephant seals are occasionally present along the waterway, but not in great numbers or for very long (NMFS, 2008b). In contrast, Pacific harbor seals and California sea lions frequent the lower Columbia River and adjacent nearshore marine areas along the LNG carrier route.

Potential impacts on marine mammals as a result of LNG marine traffic would be limited to spills or leaks of hazardous materials, disturbance due to increased noise and ship traffic levels, and vessel strikes. Impacts on other marine mammals due to spills or leaks of hazardous materials would be similar to those described for the Steller sea lion.

To date, the various impacts on Pacific harbor seals, California sea lions, northern fur seals, and elephant seals from human disturbance have not been studied extensively. Close approach by humans and boats has been shown to cause sea lions and Pacific harbor seals at haulouts to go into the water (NMFS, 1992; Matthews, 2000). Repeated disturbance by humans could result in abandonment of the South Jetty of the Columbia River haulout site (Kenyon, 1962). However, due to marine mammals tolerance of current large vessel traffic along the Columbia River, it is expected that an increase of about 7 percent in commercial vessel traffic during operation of the proposed project would not significantly increase disturbance to Steller sea lions. In recent years, there are no known reports of collisions between vessels and either Pacific harbor seals or northern fur seals; however, boat collisions have resulted in the deaths of three California sea lions and two elephant seals (Caretta et al., 2007).

Within the marine portion of the waterway, increased vessel traffic could increase the risk of minimal long-term intermittent impacts on dolphins, porpoises, and whales. Vessels could collide with marine mammals regardless of vessel size and type. However, the most vulnerable cetaceans include slow-moving species or species that spend extended periods of time at the surface. In contrast, dolphins often change their behavior in response to vessels, approaching vessels to ride the wake, extending interbreath intervals, decreasing inter-animal distance, changing headings, or increase swimming speed. Dolphins might be struck by vessels due to inattentiveness, age or health, or voluminous vessel traffic (MMS, 2002). NorthernStar has stated that it will apply for an Incidental Harassment Authorization pursuant to MMPA section 101(a)(5)(D); therefore, potential impacts would be addressed as part of NorthernStar's consultation with NMFS.

Migratory Bird Treaty Act

During operation of the proposed project, an accidental or intentional breach of an LNG carrier while in transit could affect migratory birds and their habitats. Because the Columbia River estuary is one of the most important sites on the Pacific Flyway for migratory birds, the risks and impacts on migratory birds as a result of an accidental or intentional breach of an LNG carrier would be similar to those described above for the brown pelican, which is concentrated within portions of the lower Columbia River during parts of the year.

4.6.2.2 LNG Terminal

Federally Listed Species

Fish

Lower Columbia River Chinook Salmon ESU

Occurrence at the LNG Terminal – The Lower Columbia River Chinook salmon ESU may occur in the following areas associated with the proposed LNG terminal: the Columbia River, Hunt Creek, and the log pond. The Columbia River at the proposed LNG terminal site provides habitat for migrating spring- and fall-run adults from March and June and August and October, respectively (NMFS, 2005c). Spring-run out-migrating smolts occur during their second spring/summer, and fall-run out-migrating smolts occur as sub-yearlings from April through June (NMFS, 2005c; ODFW, 2005; Wade, 2000, 2002). In addition, juvenile Chinook salmon rear throughout the year in nearshore habitat of the Columbia River mainstem.

Hunt Creek, which is adjacent to the LNG terminal site, is one of three streams of the lower Columbia-Clatskanie subbasin that have been designated as containing habitat for spawning of fall Chinook salmon (Kostow, 1995). In addition, juvenile Chinook salmon rear in Hunt Creek throughout the year. The log pond potentially provides at least seasonal refugia during high flow for juvenile Chinook salmon.

Juvenile salmon entering the Columbia River upstream of Bradwood Landing are subject to a flow split upstream of Puget Island between the Columbia River shipping channel (Oregon side of Puget Island) and Cathlamet Channel (Washington side of Puget Island). Juvenile fish migrating along the Oregon side of Puget Island would pass near the proposed LNG terminal at Bradwood Landing. While the out-migrating patterns of juvenile salmonids are relatively well understood, the distribution of out-migrants as they pass Puget Island, and therefore the proposed terminal location, are less so. The majority of flow through the area is associated with the navigation channel which is along the Oregon side of Puget Island. Therefore, at a minimum, the channel oriented species such as yearling Chinook, sockeye, steelhead and Coho would likely be exposed to potential impacts at the terminal. Schreck et al. (2005) determined that smolt-sized Chinook salmon predominately occur in the main shipping channel. Additionally, Carlson et al. (2001) observed a greater percentage of fish along the channel margin on the Oregon side of the channel than the Washington side, both above and below the flow split at Puget Island. Similarly, based on sampling efforts documented by Dawley et al. (1986), fewer sub-yearling Chinook salmon appear to migrate along the Washington shore of the Columbia River just upstream of Puget Island than along the Oregon shore.

The percentage of fish that would be exposed to impacts associated with construction and operation of the LNG terminal is not clear; however, it appears that a higher percentage of out-migrating juvenile salmonids would occur on the Oregon side of Puget Island and therefore be exposed to impacts associated with LNG terminal construction (e.g., dredging) and operation (e.g., ballast and ship engine cooling water intake) activities. As described in section 4.5.2.1, additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – The lower Columbia River is designated as critical habitat (rearing, migratory corridor, and spawning PCEs) for the Lower Columbia River Chinook salmon ESU. As described above, salmon migrate through the Columbia River estuary and past the LNG terminal site en route to their spawning grounds upstream. In addition, critical habitat for juvenile rearing has been designated within nearshore habitats of the Columbia River mainstem and Hunt Creek (70 Federal Register 52630 – 52858).

The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal would affect 63 acres of designated critical habitat for the Lower Columbia River Chinook salmon ESU, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – The Bradwood Landing LNG terminal would affect salmonids and/or their designated critical habitat through various activities including:

- in-water construction activities such as:
 - dredging;
 - development of the river shoreline;
 - pile driving; and
 - log pond filling;
- terrestrial/riparian habitat modification such as:
 - bridge construction and railroad realignment; and
 - power line construction;
- water appropriation activities such as:
 - ship ballast and engine cooling water;
 - hydrostatic testing; and
 - fire suppression system testing;
- LNG terminal lighting;
- accidental spills and leaks of hazardous materials; and
- LNG terminal operations activities such as:
 - maintenance dredging;
 - routine discharge of condensate water from the SCVs; and
 - operational acoustic effects.

Potential impacts and mitigation from each of these factors are summarized in table 4.6.2-1 and described in detail in section 4.5.2.1. NorthernStar's proposed mitigation measures are summarized below (see *Compensatory Mitigation*).

Construction of the proposed LNG terminal would affect 68.5 acres of designated critical habitat for the Lower Columbia River Chinook salmon ESU. Of these, 5.0 acres would be permanently impacted by filling the log pond at the LNG terminal site. The remaining 63.5 acres within the ship berth and maneuvering area would be permanently modified by the addition of piles and other over-water structures as well as dredging.

Upper Columbia River Spring-run Chinook Salmon ESU

Occurrence at the LNG Terminal – Occurrence of the Upper Columbia River Spring-run Chinook salmon ESU at the LNG terminal site would be limited to seasonal migrations within the lower Columbia River and occasional use of Hunt Creek during summer months by juveniles. The life stages present and seasonal occurrence of the Upper Columbia River Spring-run Chinook Salmon ESU along the lower Columbia River are described in section 4.6.2.1. As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – The Columbia River is designated as critical habitat (rearing and migratory corridor PCEs) for the Upper Columbia River Spring-run Chinook salmon ESU (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal

would affect 63 acres of designated critical habitat for the Upper Columbia River Chinook salmon ESU, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Migration of Upper Columbia River Spring-run Chinook salmon past the project site and occasional use of Hunt Creek by juveniles would occur outside of the in-water work window, thus excluding them from being present during pile driving, dredging, or other in-water construction activities that may cause an avoidance reaction or result in adverse affects. Impacts on designated critical habitat for the Upper Columbia River Spring-run Chinook salmon ESU would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

Upper Willamette River Chinook Salmon ESU

Occurrence at the LNG Terminal – The Upper Willamette River Chinook salmon ESU may occur in the following areas associated with the proposed LNG terminal: the Columbia River, Hunt Creek, and the log pond. The Columbia River at the proposed LNG terminal site provides habitat for migrating adults primarily between April and May, with a peak in mid-May, and for juvenile rearing throughout the year (ODFW, 2005; Kostow, 1995; NMFS, 2005c). According to the NMFS (2005c), out-migration has been found to occur in recently emerged juveniles during the winter through early spring, in sub-yearlings during the fall through early winter, and as yearlings in the late winter through spring. Hunt Creek provides rearing habitat for juvenile Chinook salmon throughout the year. The log pond potentially provides at least seasonal refugia during high flow for juvenile Chinook salmon. As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – The Columbia River is designated as critical habitat (rearing and migratory corridor PCEs) for the Upper Willamette River Chinook salmon ESU. As described above, salmon migrate through the lower Columbia River and past the LNG terminal site en route to their spawning grounds upstream. In addition, critical habitat for juvenile rearing has been designated within nearshore habitats of the Columbia River mainstem and Hunt Creek (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal would affect 63 acres of designated critical habitat for the Upper Willamette River Chinook salmon ESU, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Impacts on designated critical habitat for the Upper Willamette River Chinook salmon ESU would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

Snake River Spring/Summer-run Chinook Salmon ESU

Occurrence at the LNG Terminal – Occurrence of the Snake River Spring/Summer-run Chinook salmon ESU at the LNG terminal site would be limited to seasonal migrations within the lower Columbia River and occasional use of Hunt Creek during summer months by juveniles. The life stages present and seasonal occurrence of the Snake River Spring/Summer-run Chinook salmon ESU along the lower Columbia River are described in section 4.6.2.1. As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – The Columbia River is designated critical habitat (migratory corridor PCE) for the Snake River Spring/Summer-run Chinook salmon ESU (58 Federal Register 68543 – 68554). Adjacent riparian zones are included in the designation, defined as those areas within 300 feet of the normal line of high water of a stream channel. Based on this designation, the proposed LNG terminal would affect 79 acres of designated critical habitat for the Snake River Spring/Summer-run Chinook salmon ESU, including 58 acres within the Columbia River, 5 acres within the log pond, and 16 acres along the shoreline of the Columbia River.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Migration of Snake River Spring/Summer-run Chinook salmon past the project site and occasional use of Hunt Creek by juveniles would occur outside of the in-water work window, thus excluding them from being present during pile driving, dredging, or other in-water construction that may cause an avoidance reaction or result in adverse affects. This species does not rear in the nearshore areas and would not be affected by those activities.

As described above, the Columbia River and adjacent riparian zone, defined as those areas within 300 feet of the normal line of high water of a stream channel, are designated critical habitat. Based on this designation, construction of the proposed LNG terminal would affect 84.5 acres of designated critical habitat for the Snake River Spring/Summer-run Chinook salmon ESU. Of these, 5 acres would be permanently impacted by filling the log pond at the LNG terminal site, and 63.5 acres within the ship berth and maneuvering area would be permanently modified by the addition of piles and other over-water structures as well as dredging. The remaining 16 acres would occur along the shoreline of the Columbia River at the proposed LNG terminal site. Although NorthernStar has committed to restoration of a portion of this area (see section 4.4.2.2), permanent conversions of designated critical habitat along the shoreline of the Columbia River are anticipated. NorthernStar's proposed mitigation measures are summarized below (see *Compensatory Mitigation*).

Snake River Fall-run Chinook Salmon ESU

Occurrence at the LNG Terminal – The Snake River Fall-run Chinook salmon ESU may occur in the following areas associated with the proposed LNG terminal: the Columbia River, Hunt Creek, and the log pond. The Columbia River at the proposed LNG terminal site provides habitat for migrating adults between August and December, out-migrating smolts between April and June, and for juvenile rearing throughout the year (Myers et al., 1998; Good et al., 2005; Bell Fisheries Handbook, 1973). Hunt Creek provides rearing habitat for juvenile Chinook salmon throughout the year. The log pond potentially provides at least seasonal refugia during high flow for juvenile Chinook salmon. As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated as critical habitat (rearing and migratory corridor PCEs) for the Snake River Fall-run Chinook salmon ESU. In addition, critical habitat for juvenile rearing has been designated within nearshore habitats of the Columbia River mainstem and Hunt Creek (70 Federal Register 52630 – 52858). Adjacent riparian zones are included in the designation, defined as those areas within 300 feet of the normal line of high water of a stream channel. Based on this designation, the proposed LNG terminal would affect 79 acres of designated critical habitat for the Snake River Fall-run Chinook salmon ESU, including 58 acres within the Columbia River, 5 acres within the log pond, and 16 acres along the shoreline of the Columbia River.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon*

ESU). Impacts on designated critical habitat for the Snake River Fall-run Chinook salmon ESU would be similar to those described above for the Snake River Spring/Summer-run Chinook salmon ESU.

Columbia River Chum Salmon ESU

Occurrence at the LNG Terminal – The Columbia River chum salmon ESU has migration corridors and both spawning and rearing habitats within the Columbia River at the proposed LNG terminal site and occasional use of Hunt Creek during summer months by juveniles. The life stages present and seasonal occurrence of the Columbia River chum salmon ESU along the lower Columbia River are described in section 4.6.2.1. As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated as critical habitat (rearing, migratory corridor, and spawning PCEs) for the Columbia River chum salmon ESU (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal would affect 63 acres of designated critical habitat for the Columbia River chum salmon ESU, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Impacts on designated critical habitat for the Columbia River chum salmon ESU would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

Lower Columbia River Coho Salmon ESU

Occurrence at the LNG Terminal – The Lower Columbia River coho salmon ESU may occur in the following areas associated with the proposed LNG terminal: the Columbia River, Hunt Creek, and the log pond. The Columbia River at the proposed LNG terminal site provides habitat for migrating adults between late August and February, peaking in October; out-migrating smolts between March and July; and for juvenile rearing throughout the year (ODFW, 2005; Good et al., 2005; Wade, 2000, 2002; Bell Fisheries Handbook, 1973). Hunt Creek provides rearing habitat for juvenile coho salmon throughout the year. The log pond potentially provides at least seasonal refugia during high flow for juvenile coho salmon. As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – Critical habitat has not been designated for the Lower Columbia River coho salmon ESU.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Although critical habitat has not been designated for the Lower Columbia River coho salmon ESU, impacts on the Lower Columbia River coho salmon ESU would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

S Snake River Sockeye Salmon ESU

Occurrence at the LNG Terminal – Occurrence of the Snake River sockeye salmon ESU at the LNG terminal site would be limited to seasonal migrations within the lower Columbia River (Gustafson et al., 1997; Good et al., 2005). The life stages present and seasonal occurrence of the Snake River

sockeye salmon ESU along the lower Columbia River are described in section 4.6.2.1. As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated critical habitat (migratory corridor PCE) for the Snake River sockeye salmon ESU (58 Federal Register 68543 – 68554). Critical habitat includes the adjacent riparian zone defined as those areas within 300 feet of the normal line of high water of a stream channel. The proposed LNG terminal would affect 79 acres of designated critical habitat for the Snake River sockeye salmon ESU, including 58 acres within the Columbia River, 5 acres within the log pond, and 16 acres along the shoreline of the Columbia River.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Migration of Snake River sockeye salmon and occasional use of Hunt Creek by juveniles would occur outside of the in-water work window, thus excluding them from being present during pile driving, dredging, or other in-water construction that may cause an avoidance reaction or result in adverse affects. This species does not rear in the nearshore areas of the lower Columbia River and would not be affected by those activities. Impacts on designated critical habitat for the Snake River sockeye salmon ESU would be similar to those described above for the Snake River Spring/Summer-run Chinook salmon ESU.

Lower Columbia River Steelhead DPS

Occurrence at the LNG Terminal – The Lower Columbia River steelhead DPS may occur in the following areas associated with the proposed LNG terminal: the Columbia River, Hunt Creek, and the log pond. As described in section 4.6.2.1, the Columbia River at the proposed LNG terminal site provides habitat for migrating adults throughout the year, with seasonal peaks in activity; out-migrating smolts occur from March to June with a peak in April or May; and rearing juveniles throughout the year (Good et al., 2005; NMFS, 2005c). Hunt Creek and the log pond potentially provide at least seasonal refugia for juvenile steelhead. As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated as critical habitat (rearing and migratory corridor PCEs) for the Lower Columbia River steelhead DPS (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal would affect 63 acres of designated critical habitat for the Lower Columbia River steelhead DPS, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Impacts on designated critical habitat for the Lower Columbia River steelhead DPS would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

Middle Columbia River Steelhead DPS

Occurrence at the LNG Terminal – Occurrence of the Middle Columbia River steelhead DPS at the LNG terminal site would be limited to migration within the lower Columbia River and occasional use of Hunt Creek during summer months by juveniles. As described in section 4.6.2.1, the Columbia River at the proposed LNG terminal site provides habitat for migrating adults throughout the year, with seasonal peaks in activity, and out-migrating smolts occur during March to June (NMFS, 2005c). As described

above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Middle Columbia River steelhead DPS (70 Federal Register 52630 – 52858). However, this DPS is not known to rear within the Columbia River at the proposed LNG terminal site. The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal would affect 63 acres of designated critical habitat for the Middle Columbia River steelhead DPS, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Impacts on designated critical habitat for the Middle Columbia River steelhead DPS would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

Upper Columbia River Steelhead DPS

Occurrence at the LNG Terminal – Occurrence of the Upper Columbia River steelhead DPS at the LNG terminal site would be limited to migration within the lower Columbia River and occasional use of Hunt Creek during summer months by juveniles. As described in section 4.6.2.1, the Columbia River at the proposed LNG terminal site provides habitat for migrating adults throughout the year, with seasonal peaks in activity, and out-migrating smolts March and June (Bell Fisheries Handbook, 1973). As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Upper Columbia River steelhead DPS (70 Federal Register 52630 – 52858). However, this DPS is not known to rear within the Columbia River at the proposed LNG terminal site. The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal would affect 63 acres of designated critical habitat for the Upper Columbia River steelhead DPS, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Impacts on designated critical habitat for the Upper Columbia River steelhead DPS would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

Upper Willamette River Steelhead DPS

Occurrence at the LNG Terminal – Occurrence of the Upper Willamette River steelhead DPS at the LNG terminal site would be limited to migration within the lower Columbia River and occasional use of Hunt Creek during summer months by juveniles. As described in section 4.6.2.1, the Columbia River at the proposed LNG terminal site provides habitat for migrating adults throughout the year, with seasonal peaks in activity, and out-migrating smolts between March and July (Bell Fisheries Handbook, 1973). As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Upper Willamette River steelhead DPS (70 Federal Register 52630 – 52858).

However, this DPS is not known to rear within the Columbia River at the proposed LNG terminal site. The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal would affect 63 acres of designated critical habitat for the Upper Willamette River steelhead DPS, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Impacts on designated critical habitat for the Upper Willamette River steelhead DPS would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

Snake River Basin Steelhead DPS

Occurrence at the LNG Terminal – Occurrence of the Snake River Basin steelhead DPS at the LNG terminal site would be limited to migration within the lower Columbia River and occasional use of Hunt Creek during summer months by juveniles. As described in section 4.6.2.1, the Columbia River at the proposed LNG terminal site provides habitat for migrating adults throughout the year, with seasonal peaks in activity, and out-migrating smolts pass through the lower Columbia River between March and June (Bell Fisheries Handbook, 1973). As described above (see *Lower Columbia River Chinook Salmon ESU*), additional analysis of salmonid occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Snake River Basin steelhead DPS (70 Federal Register 52630 – 52858). However, this DPS is not known to rear within the Columbia River at the proposed LNG terminal site. The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation. The proposed LNG terminal would affect 63 acres of designated critical habitat for the Snake River Basin steelhead DPS, including 58 acres within the Columbia River and 5 acres within the log pond.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on salmonids are described above (see *Lower Columbia River Chinook Salmon ESU*). Impacts on designated critical habitat for the Snake River Basin steelhead DPS would be similar to those described above for the Lower Columbia River Chinook Salmon ESU.

North American Green Sturgeon

Occurrence at the LNG Terminal – As described in section 4.6.1.1, the North American green sturgeon is the most marine-oriented of sturgeons occurring in North America. They are known to concentrate in the Columbia River estuary during the late summer and fall months. As described in section 4.5.2.1, additional analysis of fish occurrence at the LNG terminal site will be included in the revised BA and EFH Assessment.

Critical Habitat – Critical habitat has not been designated for the North American green sturgeon.

Impacts and Mitigation – Potential impacts from construction and operation of the Bradwood Landing LNG terminal on the North American green sturgeon would be similar to those described above for Lower Columbia River Chinook Salmon ESU.

Compensatory Mitigation

As summarized in table 4.6.2-1, project design, construction, and operation plans have been modified to avoid or minimize impacts on salmonid ESU/DPSs and their designated critical habitat. These efforts would be ongoing during construction in order to capitalize on avoidance and minimization opportunities that cannot be predicted. However, both direct and indirect impacts on salmonids would result from construction and operation of the proposed project. NorthernStar has committed to provide an overall net benefit to the environment of the lower Columbia River ecosystem.

Following construction of the LNG terminal, habitat and ecosystem function would be restored in place. Permanent impacts on aquatic resources would be mitigated by restoring habitat with similar ecological function. The FERC received numerous comments stating that the mitigation proposed by NorthernStar does not adequately compensate for impacts on aquatic resources associated with the project. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. To ensure that the mitigation proposed for the Bradwood Landing Project adequately compensates for project-related impacts, we have recommended that NorthernStar continue to consult with the appropriate natural resource agencies to finalize its Compensatory Mitigation Plan. The final Compensatory Mitigation Plan will be filed along with agency comments and applicable approvals with the Secretary prior to construction of the project.

Salmon Enhancement Initiative

As part of the Bradwood Landing Project, NorthernStar proposes to implement an SEI to contribute to the recovery of salmon and the lower Columbia River ecosystem. NorthernStar proposed the SEI as a voluntary action that would be above and beyond the mitigation measures used to avoid, minimize, rectify, reduce, and/or compensate for environmental impacts that are required by the regulations. However, various permit requirements would ensure its implementation if the project is authorized. NorthernStar's SEI would potentially contribute significantly to the conservation and recovery of salmonids (and other species) protected under the ESA.

The SEI would entail providing funding for salmon preservation, enhancement, and restoration projects on the lower Columbia River that would likely total more than \$50 million over the life of the Bradwood Landing Project. Of these monies, \$7 million would be available for an Early Action Plan to be implemented during the period between the start of project construction and the start of project operation. The remainder of the monies would be available for long-term measures that would be funded through yearly installments of \$1.3 million beginning after the project becomes operational. The National Fish and Wildlife Foundation's (NFWF) Western Partnership Office in Portland, Oregon would serve as the fiscal agent for SEI funds.

NorthernStar would work with the LCFRB to develop the SEI. The SEI would include initial and ongoing outreach to, and consultation with, watershed and estuary restoration groups, tribes, agencies, and other entities involved in preservation, restoration, and other salmon and ecological enhancement efforts on the lower Columbia River. The LCFRB would lead and facilitate this outreach and consultation process to:

- design and develop SEI processes and procedures, including the criteria for project selection, processes for allocating funds, and means of evaluating performance;
- establish a Steering Committee to help develop the Early Action Plan;

- authorize the allocation of SEI funding upon approval of funding allocation plans by the Steering Committee; and
- evaluate the ecological and salmon benefits of SEI proposals and actions with the goal of measuring progress and adaptively improving performance of the SEI to ensure the highest value and resource benefit for SEI investments.

The LCFRB would convene, administer, and chair the Steering Committee. Those invited to participate on the Steering Committee would include, but not be limited to, representatives of the LCFRB, other regional watershed and estuary restoration groups, NMFS, FWS, ODFW, WDFW, and tribes.

Allocation of SEI funds would be guided by project selection criteria, the application of best available science and plans, and a collaborative process facilitated by the LCFRB. This process is designed to serve the SEI, but it could also demonstrate the concept of using best available science and plans, and a collaborative process, to optimize the investment of other funds (e.g., mitigation and environmental fines, judgments, and settlements) for better efficiency and ecological effectiveness.

The LCFRB and the Steering Committee would prepare and submit to NorthernStar and the NFWF an annual implementation plan and budget that identifies recommended actions and projected funding allocations for the upcoming year. Funds would be released after the Steering Committee's plan and budget have been approved by the NFWF. The LCFRB and the Steering Committee would prepare and make available to the public an annual progress report that describes the activities of the SEI, including funding allocations and project summaries that describe the status and ecological outcomes of individual projects.

Project Selection Criteria. The following selection criteria regarding geographic scope, focal species, biological criteria, and other considerations would guide selection of specific SEI salmon and ecosystem preservation, restoration, and enhancement projects for both the Early Action Plan and long-term funding program.

SEI projects would be located within the lower Columbia River watershed, which includes the Columbia River estuary, mainstem area, and associated Oregon and Washington tributaries. Although the Steering Committee would have final authority to determine the geographical extent of the scope of the SEI, the lower Columbia River has been defined as that portion of the river below Bonneville Dam to the mouth.

The primary purpose of SEI projects would be the recovery of ESA-listed salmon and steelhead stocks as well as the general ecological enhancement of the lower Columbia River ecosystem. However, SEI projects would also benefit other aquatic and terrestrial listed and non-listed species such as the Pacific and river lampreys, bull trout, smelt, bald eagle, and Columbian white-tailed deer.

Projects would be designed to accomplish one or more of the following functions:

- protect existing functional habitats and the processes that sustain them;
- strive for no further degradation of habitat or supporting processes;
- re-connect isolated habitat;
- restore watershed and estuarine processes (ecosystem function);
- restore habitat structure, including developing LWD banks for restoration materials;
- create new habitat where previous habitat is not recoverable; and/or
- reduce mortality of ESA-listed fish species and improve abundance.

Other considerations in project design would include:

- leverage, and be combined with, other monies to maximize benefits;
- seize time-limited opportunities;
- support research that addresses critical uncertainties and informs restoration decision-making, as well as programs that improve the ability to monitor, evaluate, and enhance the performance of restoration efforts;
- support efforts to use watershed and salmon recovery science and plans to inform and improve regulatory processes and decision-making (e.g., mitigation) for net resource benefit; and
- address specific recovery needs identified for lower Columbia salmonids in the following plans:
 - the (Washington) *Lower Columbia River Salmon Recovery and Fish & Wildlife Plan* (LCFRB, 2004), adopted by the NMFS as the *Interim Regional Recovery Plan of the Washington Management Unit for the Lower Columbia River* on February 3, 2006;
 - future revisions, enhancements, and additions to the above plans and supporting documents, including the final *Lower Columbia River Salmon Recovery and Fish & Wildlife Plan* (Oregon and Washington) when completed and adopted by the NMFS;
 - the *Northwest Power and Conservation Council Fish and Wildlife Program Subbasin Plan for the Lower Columbia Mainstem and Estuary* (Northwest Power and Conservation Council, 2004); and
 - the *Lower Columbia River Estuary Program Comprehensive Conservation and Management Plan* (Lower Columbia River Estuary Partnership, 1999).

Early Action Plan. The SEI would include an Early Action Plan to be implemented between the period after the start of construction and prior to operation of the LNG terminal. NorthernStar's initial \$7 million commitment would be payable, through the NFWF, for projects, programs, and administrative expenses contained in the Early Action Plan upon its approval by the Steering Committee. The Early Action Plan would be designed to:

- employ the project selection criteria, emphasizing use of best available science and plans to develop a prioritized list of high-value, short-term measures (projects, programs, and other efforts) to support recovery of salmon and the lower Columbia River ecosystem;
- outline a 3-year implementation work plan to fully utilize the SEI's initial funding with a schedule for short-term measures and administrative costs on a year-by-year basis;
- execute the Early Action Plan year by year, evaluating performance, new information and opportunities, and the need to adaptively revise the plan with the benefit of this evaluation;
- allocate the funds for projects in both Oregon and Washington; and

- address a potentially wide range of projects and initiatives that may include focused research that informs restoration and recovery decision-making (such as fish mortality issues and strategies), an LWD bank, and control of invasive species, as well as habitat preservation and restoration.

Although the Steering Committee would need to evaluate individual project proposals under the Early Action Plan, the following examples are the kinds of projects and programs that could be funded through the SEI:

- establishment of an LWD bank program to support habitat restoration projects on the lower Columbia River. This would include development of the program plan and procedures and establishment of the infrastructure necessary for implementation;
- implementation of high priority estuarine restoration and enhancement projects identified in the *Columbia River Estuary Recovery Plan Module* (NMFS, 2006d). Project priorities would focus on the following: restoration of riparian habitat, modification of in-water structures to improve estuarine processes and reduce predation effects, and breaching or lowering of dikes/levees to restore access to off-channel habitats;
- implementation of key restoration and enhancement projects on the lower 12 miles of the Grays River, based upon high priority needs and locations identified in the *Lower Columbia Salmon Recovery and Fish & Wildlife Subbasin Plan*. Projects would complement ongoing restoration efforts and would focus on key habitat parameters for chum, Chinook, winter steelhead, and coho;
- acquisition of and restoration of portions of Svensen Island not dedicated to compensatory mitigation (upper Svensen Island);
- implementation projects identified by Oregon Watershed Councils that address restoration needs identified by initial limiting factors analysis performed by the ODFW as part of its Recovery Plan process;
- implementation of one or more comprehensive restoration projects on Mill, Abernathy, and Germany Creeks, focusing on in-stream habitat complexity and diversity. The project(s) would implement a primary restoration component of the Intensively Monitored Watershed program and would be designed to test the effectiveness and biological response of habitat restoration actions; and
- support development and implementation of innovative mitigation strategies and programs, including mitigation banks, that further the purpose and intent of the SEI and maximize net resource benefits and integrate processes associated with mitigation actions.

Long-Term Annual Funding. After the LNG terminal begins operation, NorthernStar would fund its SEI through an annual contribution of \$1.3 million for as long as the LNG terminal operates, approximately 30 to 40 years (see section 2.9). Long-term funding for the SEI would be paid to the NFWF or its successor in a lump sum of \$1.3 million annually upon approval by the Steering Committee of an annual funding allocation package. The long-term funding would also be used to develop and implement annual funding allocation packages employing the criteria described above (which emphasize use of best available science and plans) to develop a prioritized list of high-value projects, programs, and other efforts to support recovery of salmon and the lower Columbia River ecosystem. If, in the judgment

of the chair/convenor of the Steering Committee, broad agreement on a funding allocation package may not be achieved, funding decisions may be deferred to the next cycle.

Projects covered under the long-term funding program would be similar in nature to projects covered under the Early Action Plan, but may, at the discretion of the Steering Committee, put relatively greater emphasis on adaptive management and restoration project maintenance, support for monitoring, and mortality reduction measures. In fact, it is likely that the list of example projects listed under the Early Action Plan is longer than initial funding could support. Therefore, projects on that list not funded under the Early Action Plan would be immediate candidates for funding under the long-term funding program.

Another category of beneficial actions likely to attract funding from the long-term funding component of the SEI is the ongoing maintenance and further incremental adaptive management of projects either funded by the Early Action Plan or by others. In many cases, some low level of ongoing funding may be critical to achieving original goals for the project or for attaining newly recognized opportunities. These funds are often difficult to get through other funding mechanisms because they must compete for funding with projects that appear to have higher increments of value. The lack of funding or the timing of funding opportunities may allow problems to persist and benefits to languish or disappear. The Steering Committee could be given the flexibility to allocate meaningful funding to ongoing needs so that a reasonable level of funding is available, as needed, to meet these priorities.

Evaluation of Enhancement Efforts. The LCFRB and Steering Committee would evaluate and, where feasible, quantify both proposed SEI actions for their potential benefit to focal species and the lower Columbia River ecosystem as well as the performance of SEI actions after they have been implemented. The monitoring, modeling, research, analysis, and adaptive management associated with evaluation should be considered priority measures by the Steering Committee and could be included in funding allocation packages.

Steller Sea Lion

Occurrence at the LNG Terminal

As described in section 4.6.1.1, although Steller sea lions generally occur downstream of Tongue Point (CRM 19), recent tagging efforts have shown that Steller sea lions move between the mouth of the Columbia River and the Bonneville Dam, foraging for food from mid-December through February, and as late as May (Stansell et al., 2007). In 2002, no Steller sea lions were observed at the Bonneville Dam; however, since that time, documented occurrences of Steller sea lions have increased. As described in table 4.6.2-2, during the 2007 hazing observation period (January 1 through May), nine individual Steller sea lions were documented. As of March 16, observers have documented 42 individual Steller sea lions hauled out at Phoca Rock (10 miles downstream of Bonneville Dam) in 2008, thus representing just over a four-fold increase from the number of individuals counted in 2007 (Stansell, 2008). Steller sea lions present at the Bonneville Dam and Phoca Rock would transit past the LNG terminal at least twice (once on the way up to the dam, and once to return to the ocean). Biologists visiting the proposed LNG terminal site on March 13, 2006 observed a single sea lion foraging in the Columbia River, but it is not known if this individual was a Steller sea lion or the more common California sea lion. The sea lion was eating and “playing” with a large silver fish in the area between the proposed LNG terminal and the upstream end of Tenasillahe Island.

TABLE 4.6.2-2							
Numbers of Pinnipeds Observed at Bonneville Dam by Year							
	2002	2003	2004	2005	2006	2007	2008
Maximum number of pinnipeds	31	111	105	85	85	80	Not yet complete
Maximum number of California sea lions	30	106	101	80	72	69	Not yet complete
Maximum number of Steller sea lions	0	3	2	4	10	9	42 ^b
Maximum number of Pacific harbor seals	1	2	2	1	3	2	Not yet complete
Date of first California sea lion observation ^a	March 20	March 14	February 22	February 20	February 9	January 8 November 8	November 8
Date of last California sea lion observation ^a	May 17	May 27	May 26	June 10	June 5	May 26	Still observing
Date of first Steller sea lion observation ^a	--	March 23	April 17	December 6	December 10	November 6	November 6
Date of first Pacific harbor seal observation ^a	unknown	unknown	unknown	December 12	December 12	January 18 August 28	August 28
^a The dedicated study period occurs between January and May, and possibly into June. All sightings outside this time frame are incidental observations by dam personnel.							
^b Sightings in 2008 accurate through March 16, 2008.							
Source Stansell, 2008							

It is unknown if individual Steller sea lions stay at the dam from November through mid-May, or if they transit back to the ocean during these months, as they are neither branded nor satellite-tagged (Jeffries, 2008). It is speculated that Steller sea lions are not moving up and down the river like the satellite tagged California sea lions, because they return to the dam the day following hazing activities; however, it is difficult to be certain which animals are present (Jeffries, 2008; Stansell, 2008; Brown, 2008). In addition, the general patterns are neither consistent nor constant, and there is variability with each individual animal (Brown, 2008).

If individuals do transit back and forth between the ocean and the dam, they would pass by the LNG terminal location during the in-water construction period when pile driving and dredging activities would occur. Potential disturbance from noise impacts would not be expected to be significant because the Steller sea lions are hazed along with the California sea lions in the ongoing effort to protect threatened and endangered salmon as they arrive at and pass the dam (Jeffries, 2008). Hazing, which involves both underwater and air noise deterrents, begins at different times, depending on several factors (Jeffries, 2008). In 2007, hazing began in late February and ended in late May (Stansell et al., 2007). Some animals start to leave the dam area when they hear the sound of the vessel engines (Jeffries, 2008).

It is important to note that Steller sea lions that move upriver as far as Bonneville Dam endure daily (or multiple days per week) hazing events that change their behavior and yet they continue to return to the area to feed. There are no known sturgeon concentration areas in the Columbia River near the terminal that would provide the same feeding opportunity as the situation at the dam. Therefore, it is likely that pinnipeds, and specifically California sea lions and Steller sea lions, occurring in the vicinity of the LNG terminal site would be in transit to the dam or back down to the ocean and would not be expected to linger near the LNG terminal.

Critical Habitat

As described in section 4.6.2.1, the nearest occurrence of designated critical habitat for the Steller sea lion is at Orford Reef, approximately 280 miles south of the Columbia River mouth (58 Federal Register 45269 – 45285).

Impacts and Mitigation

Since Steller sea lions are expected to move through the area near the LNG terminal site, it is possible that underwater sound pressure levels during construction activities at the LNG terminal could adversely impact any sea lions occurring in the area. In addition, construction and operation of the LNG terminal could result in accidental spills or leaks of hazardous materials or result in use of the LNG terminal site as a haulout by Steller sea lions.

Noise – Noise from dredging, general construction, and pile driving activities would be generated at the proposed LNG terminal site. Although dredges are major sources of underwater noise in the Columbia River, Steller sea lions show a high degree of site fidelity to the haulout located at the South Jetty of the Columbia River despite the COE conducting regular maintenance dredging of the navigation channel. Therefore, dredging activities would not be expected to affect the Steller sea lion.

The portion of the river near Bradwood is subject to frequent vessel traffic from tugs, barges, and large container ships headed upstream to other ports of call (e.g., Longview, Kalama, Portland). In an opportunistic recording of a tug pushing a barge in the Snohomish River, Washington, the broadband level reached a maximum value of 146 dB in a 1-second period and a sustained average of 137 dB over a period of 50 seconds at 40 meters (131 feet) (Burgess et al., 2005). Furthermore, Steller sea lions transiting past the LNG terminal site are often enroute to the Bonneville Dam to feed, where background levels may be much higher there as a result of the dam operations. Once pinnipeds (including Steller sea lions) arrive at the dam in winter through May, hazing operations take place almost daily; that level of underwater and air noise harassment does not discourage these animals from returning to the site the same day or the next day (Stansell, 2008; Gearin, 2008; Jeffries, 2008).

As described in section 4.5.2.1, pile driving activities would occur between the hours of 7:00 AM and 10:00 PM for about 60 days spread over the NMFS-recommended in-water work window (between November 1 and February 28). Using an impact hammer to drive 96-inch-diameter steel piles may generate underwater sound pressure levels up to 227 dB (re: 1 μ Pa) at 16 feet. Close to piles, the RMS is typically about 10 to 15 dB lower than the peak. However, this level is dependent not only on the pile and hammer characteristics, but also on the geometry and boundaries of the surrounding underwater environment (Hastings and Popper, 2005). This is above the threshold for injury to Steller sea lions (190 dB_{rms}) and the threshold for disturbance (160 dB_{rms}). To minimize potential impacts on Steller sea lions due to increased noise during construction and pile driving activities, NorthernStar would establish a construction safety zone, buffer zone, and a noise impact zone around pile driving and construction activities at the LNG terminal site.

Based on a 4.5 dB practical spreading loss, the distance to the 160 dB_{rms} re: 1 μ Pa isopleth would be 3,281 feet. The use of bubble curtains, dewatered cofferdams, and special noise-reducing pile caps would assist with minimizing the distance to the 160 dB_{rms} (re: 1 μ Pa) isopleth. As discussed in section 4.5.2.1, in-water monitoring would be completed to document the effectiveness of the pile driving noise mitigation and to determine if additional noise mitigation measures are needed to reduce the distance to the 160 dB_{rms} (re: 1 μ Pa) isopleth.

Safety Zone – A Safety Zone would initially be established within a 500-foot radius around pile driving activities. Once pile driving begins, a qualified underwater acoustic monitor would record sound pressure levels to determine the 190 dB_{rms} isopleth (a continuous line on a map connecting equal points). That would become the new Safety Zone boundary. No pile driving would be initiated until a qualified marine mammal monitor surveys the Safety Zone. If the monitor sights a Steller sea lion in the Safety Zone, pile driving start-up would be delayed until the monitor determines, through sighting or by waiting approximately 15 minutes, that the animal or animals have likely moved beyond the Safety Zone. Once pile driving begins on an individual pile, however, that segment would be completed without cessation notwithstanding any pinniped presence in the Safety Zone, since continuous sound is considered more protective than stopping and starting, which might allow pinnipeds to return to the area where they would be subject to additional start-up sounds.

Because of the potential that pile driving may be carried out if pinnipeds are present in the Safety Zone (i.e., the animals may be exposed to sound pressures in excess of 160 dB), NorthernStar has stated that it will apply for an Incidental Harassment Authorization pursuant to MMPA section 101(a)(5)(D). The NMFS and NorthernStar suggested that the level of detail required for the issuance of an Incidental Harassment Authorization be included in this final EIS. NorthernStar submitted additional information to the FERC relating to potential impacts on marine mammals on April 17, 2007. However, this information was not submitted at a date that allowed sufficient time for independent verification by the FERC staff prior to inclusion in this document.

The NMFS may elect to use relevant portions of the final EIS in order to facilitate the application and permitting process. In some instances, the NMFS may require additional mitigation and monitoring measures to ensure that the taking would result in the least practicable adverse impact on affected marine mammal species or stocks. These could include measures considered but eliminated in this final EIS or as yet undeveloped measures. The public will have an opportunity to provide information to the NMFS through the MMPA process during the comment period following the NMFS's Notice of Receipt of the application for an Incidental Harassment Authorization or request for the implementation of regulations governing incidental taking (i.e., Letter of Authorization). In addition, the public will also have an opportunity to provide information following publication of the proposed rule. Any mitigation measures not considered in the final EIS but required through the MMPA process may require evaluation by NMFS in accordance with the NEPA.

The exact sequence of pile driving cannot be known until a contractor is hired and develops a construction sequence. The sound monitoring to establish the 190 dB_{rms} isopleth or 200 dB instantaneous peak sound pressure level would either be done with the largest pilings at the beginning, and the protective zones established at that point and used for all the pilings (most protective approach), or if the pilings have to be driven from the shore out, progressing from smaller to larger and shallower to deeper water, then monitoring and establishment of the protective zones would be done for each size of piling.

Buffer Zone – In addition to the Safety Zone described above, NorthernStar proposes to establish a Buffer Zone for Steller sea lions. The Buffer Zone would be established by monitoring once pile driving begins. It would be established at the 160 dB_{rms} isopleth. No pile driving would be initiated until a qualified marine mammal monitor surveys the Buffer Area. If the qualified marine mammal monitor observes a Steller sea lion in the Buffer Area on a line of movement toward the Safety Zone, pile driving would be delayed until the monitor determines, through sighting or by waiting approximately 15 minutes, that the Steller sea lion is on a line of movement that will take it away from the Safety Zone. Once pile driving begins on an individual pile, however, that segment would be completed without cessation notwithstanding any Steller sea lion presence in the Buffer Zone, since continuous sound is considered more protective than stopping and starting, which might allow Steller sea lions to return to the area where they would be subject to additional start-up sounds.

Other In-water and On-shore Equipment Noise Impact Zone – Construction activities not related to pile driving would also be expected to generate noise that could disturb pinnipeds in the unlikely event they are in the vicinity of LNG terminal construction activities. Therefore, NorthernStar proposes to establish a 50-foot radius Impact Zone around ongoing construction activities (the Impact Zone would include any areas of the Columbia River within a 50-foot radius of construction). Each day before non-pile driving construction begins, a qualified marine mammal monitor would search the Impact Zone for Steller sea lions. If a Steller sea lion is sighted within the Impact Zone, construction within the Impact Zone would be delayed until the monitor determines that no Steller sea lion is present within the Impact Zone.

Accidental Spill or Leaks of Hazardous Materials – Spills, leaks, or accidental releases of fuels, lubricants, or other hazardous substances could potentially occur during construction or operation of the proposed LNG terminal. A spill, leak, or accidental release of hazardous materials could result in mortality to the Steller sea lion. NorthernStar would minimize potential impacts associated with spills or leaks of hazardous materials during construction by implementing the spill prevention and response procedures in its terminal ESC Plan (see section 4.3.2.3). As discussed in section 4.3.2.3, a 5-foot-high perimeter berm would surround the portion of the LNG terminal containing the LNG storage tanks and vaporization units. The berm would provide containment in the unlikely event of a tank rupture; thus minimizing impacts on Steller sea lions.

Use of the LNG Terminal Site as a Haulout – Steller sea lions have been documented using various manmade objects as haulouts (e.g., navigation buoys, jetties, and docks). However, Steller sea lion haulout sites do not occur along the Columbia River upriver from the South Jetty. Following construction, the proposed LNG terminal site would be well above the water surface, leaving only vertical pilings in the water. The primary shoreline modification would be the construction of the perimeter berm above the high water mark, which would have a steeper slope than the existing shoreline. Therefore, Steller sea lions would not be expected to use the LNG terminal as a haulout site during operation of the proposed project.

Columbian White-tailed Deer

Occurrence at the LNG Terminal

The ORNHIC provided two database records of the Columbian white-tailed deer in the vicinity of the proposed LNG terminal site, about 0.5 mile southeast along the Bradwood cliffs and about 0.8 mile northwest on Tenasillahe Island. Columbian white-tailed deer are also known to occur on Puget Island, which is across the Columbia River (about 0.4 to 0.5 mile to the east) from the proposed LNG terminal.

Critical Habitat

Critical habitat has not been designated for the Columbian white-tailed deer.

Impacts and Mitigation

Potential impacts on Columbian white-tailed deer from construction and operation of the proposed LNG terminal include habitat modification; increased noise and disturbances; and collisions with vehicle or railway traffic. These impacts are discussed below.

Habitat Modification – About 59 acres of potentially suitable habitat for the Columbian white-tailed deer would be temporarily or permanently impacted by the LNG terminal facilities. The LNG terminal facility would be surrounded by an 8-foot-high fence, and thus would permanently exclude

Columbian white-tailed deer. Potentially suitable habitat for Columbian white-tailed deer at the LNG terminal site and its associated facilities includes forest (coniferous, deciduous, riparian, and early seral forests as well as forested wetlands), scrub shrub (upland scrub-shrub and palustrine scrub-shrub wetland), and palustrine emergent wetlands. These habitats are discussed below.

Construction and operation of the LNG terminal facilities would temporarily or permanently impact about 33.5 acres of forested habitats (22.9 acres temporary removal and 10.6 acres permanent removal). About 8.6 acres of this impact would be on commercially managed coniferous forest that could be harvested within 5-15 years and 5.6 acres are seral coniferous forests that are likely to be harvested in 20-40 years. Due to the location of these habitats in the hills above the LNG terminal site where the power line would be located, these habitats provide only marginally suitable habitat for Columbian white-tailed deer. The remaining 19.3 acres (12.7 acres temporary removal and 6.6 acres permanent removal) impacted by construction and operation provides potentially suitable foraging, resting, and fawning habitat for Columbian white-tailed deer. Following construction, the 22.9 acres of temporarily impacted forest habitats would be replanted in-kind with native trees as described in NorthernStar's terminal ESC Plan. However, as described in section 4.4.2.2, impacts on forested communities would be considered long-term because of the time required to restore the woody vegetation to its preconstruction condition. NorthernStar has developed a monitoring plan and performance standards to measure successful revegetation of the site. If necessary, NorthernStar would take steps to control and remove noxious and invasive species.

In addition, construction and operation of the LNG terminal facilities would impact about 19.0 acres of scrub-shrub habitats (12.3 acres temporary removal and 6.7 acres permanent removal). Of these, 10.7 acres of temporarily affected habitats are upland communities dominated by non-native Scotch broom. The remaining 8.3 acres provide potentially suitable foraging, fawning, and resting habitat for Columbian white-tailed deer. Similar to forested areas, restoration would follow the terminal ESC Plan. Due to the time required to restore the woody vegetation to its preconstruction condition, restoration is expected to be complete within 3 to 5 years.

About 11.3 acres of palustrine emergent wetland habitat (1.1 acres temporary removal and 10.2 acres permanent removal) would be impacted by construction and operation of the LNG terminal facilities. Loss of these wetland habitats could displace deer that forage and seek cover in these areas. However, it is unknown if this species uses these habitats at the proposed LNG terminal site and additional potentially suitable habitat occurs about 1,500 feet downstream of the proposed LNG terminal site. As discussed in section 4.4.1.2, restoration of wetland areas would be in accordance with NorthernStar's terminal ESC Plan. These areas would be expected to recover fully within 1 to 3 years.

The LNG terminal site would occupy a narrow strip of bottomland habitat that separates the Columbia River from forested hills that may provide a migratory corridor for Columbian white-tailed deer moving between the Wauna-Westport area, Tenasillahe Island, and/or Brownsmead. In addition, Columbian white-tailed deer moving between Tenasillahe and Puget Islands may use this corridor. Although movements between subpopulations may be infrequent, they are important for maintaining gene flow between the subpopulations. Because each subpopulation of Columbian white-tailed deer is small (less than 200 individuals), the risk of inbreeding depression within any subpopulation occurs unless there is occasional genetic exchange between members of other subpopulations. Both construction and operation of the LNG terminal could block or interfere with movement of Columbian white-tailed deer between these subpopulations.

Increased Noise and Disturbances – Increased noise and physical disturbances associated with construction and operation of the proposed LNG terminal could adversely affect Columbian white-tailed deer by disruption of foraging and resting behaviors and temporary displacement in response to

construction disturbance if this species is present during construction. As described in section 4.10.2.2, NorthernStar conducted noise attenuation modeling to predict noise levels that would be generated by construction and operation of the LNG terminal. Results of this modeling found that the average increase in ambient noise during construction would range from 5 to 24 dBA (depending on the use of selective noise mitigation measures). During operation, noise levels are estimated to increase by 5 dBA over ambient conditions. This impact would be long-term in duration, but with time, any Columbian white-tailed deer using the area would likely become habituated to the changed environment.

Collisions with Vehicle or Railway Traffic – As discussed in section 4.8.2.7, construction workers traveling to and from the proposed LNG terminal could generate up to 1,500 vehicle trips per day. During operation, the LNG terminal would generate an average of 125 daily trips, or 75 daily trips over baseline conditions. Although Columbian white-tailed deer have not been confirmed to use either Clifton or Bradwood Roads, some level of use is assumed in the lowlands that surround the LNG terminal. Elevated traffic levels would increase the likelihood of collisions between Columbian white-tailed deer and vehicles transiting to or from the LNG terminal. This impact would be greatly reduced by posting speed limit and deer warning signs on all roads. To further reduce potential impacts on deer, NorthernStar would implement a training and awareness program for all personnel constructing or accessing the LNG terminal. This program would teach personnel about the natural history and endangerment factors for the Columbian white-tailed deer, the reasons for protecting this species, and the responsibilities of personnel in preventing impacts on this species. In addition, construction workers would be bussed from a temporary parking lot located southeast of the Taylorville interchange at Highway 30, thereby reducing traffic along Clifton and Bradwood Roads.

The existing railway, which is currently in service but not in use, may be used to transport construction materials to the LNG terminal site. Rail service would likely be infrequent and the risk of collision would be low due to the expectedly low frequency of traffic on the railway and the short-term use of the line (during construction). Once construction has been completed, exposure would be eliminated. Potential for collisions would be greatly reduced by requiring that train operators sound the horn on approach to alert Columbian white-tailed deer that may be present. In addition, NorthernStar would make information available to train operators about the risk of collision and the importance of protecting Columbian white-tailed deer.

Marbled Murrelet

Occurrence at the LNG Terminal

The Priority Habitats and Species (PHS) and ORNHIC have no records of the marbled murrelet within 2 miles of the proposed LNG terminal (ORNHIC, 2004 and 2006). Forests in the vicinity of the proposed LNG terminal are relatively young and generally lack characteristics that contribute to nesting, foraging, and roosting habitats for marbled murrelets. However, marginally suitable late-successional habitat for this species is located within a narrow fringe of mature conifers on the bluffs just upstream of the LNG terminal.

Critical Habitat

The closest critical habitat unit to the proposed LNG terminal is OR-01-a, which is about 2.5 miles southeast of the LNG terminal site near Wauna, in Clatsop County, Oregon (61 Federal Register 26255 – 26320).

Impacts and Mitigation

In its April 20, 2007 letter to the FERC, the FWS commented that suitable nesting habitat for the marbled murrelet may occur in several locations within the project area. Furthermore, the FWS recommended that, unless there are documented reasons to conclude that nesting is not occurring, NorthernStar should conduct surveys to determine the nesting status of marbled murrelets in the project area. In response to this letter, NorthernStar has stated that it will conduct field investigations to confirm that potentially suitable habitat occurs in the project area. If suitable habitat is identified, NorthernStar would either conduct surveys to determine presence of marbled murrelets or would simply assume presence of marbled murrelets in the project area.

If present, marbled murrelets could potentially be affected by construction and operation of the proposed LNG terminal if nest trees and surrounding habitat were to be removed, or if construction were to occur in the vicinity of an active nest. Indirect impacts could include short-term avoidance of foraging habitat and increased visual and auditory disturbance due to construction activities. In addition, increased noise and other physical disturbances associated with operation of the LNG terminal could temporarily cause marbled murrelets to avoid the area. As noted previously, the FERC staff is currently revising its BA and EFH Assessment for the Bradwood Landing Project, which will be resubmitted to the FWS with a request to initiate formal consultation in compliance with section 7 of the ESA. Additional analysis of the potential for occurrence of and potential impacts on marbled murrelets in the vicinity of the LNG terminal site will be included in the revised BA and EFH Assessment. The FERC would not allow construction of the project to proceed until after we have completed formal consultation.

Northern Spotted Owl

Occurrence at the LNG Terminal

A search of the ORNHIC and PHS databases found no northern spotted owl nest site records within a 2-mile search radius of the proposed LNG terminal. The nearest known active spotted owl nest is located between 3 and 4 miles south of the LNG terminal in the Clatsop State Forest (ORNHIC, 2006). Forests in the vicinity of the proposed LNG terminal site are relatively young and generally lack characteristics that contribute to nesting, foraging, and roosting habitats for spotted owls. Marginally suitable late-successional habitat for this species is limited to a narrow fringe of mature conifers that occurs on the bluffs just upstream of the LNG terminal.

Critical Habitat

The closest critical habitat unit to the proposed LNG terminal is WA-39 (57 Federal Register 1796 – 1838), which is located over 50 miles east of the LNG terminal in eastern Cowlitz County (FWS, 1992b).

Impacts and Mitigation

Because there are no known occurrences of northern spotted owls in the vicinity of the LNG terminal, only marginally suitable habitat occurs within the areas affected by the LNG terminal facilities, and the distance to the nearest critical habitat unit (50 miles east), it is unlikely that northern spotted owls would be affected by construction or operation of the LNG terminal.

Streaked Horned Lark

Occurrence at the LNG Terminal

As described in section 4.6.1.1, streaked horned larks are known to occupy breeding sites on five dredge spoil islands along the lower Columbia River. The nearest breeding site occurs on an unnamed island located just upstream of Tenasillahe Island about 1 mile north of the proposed LNG terminal site (Pearson and Altman, 2005). In addition, dredge spoil areas associated with the LNG terminal and the Wahkiakum County Sand Pit site on Puget Island provide potentially suitable nesting habitat for the streaked horned lark. Although some streaked horned larks are migratory, potential habitat may be occupied throughout the year.

Critical Habitat

Critical habitat has not been designated for the streaked horned lark.

Impacts and Mitigation

The greatest potential for activities associated with construction and operation of the LNG terminal to adversely impact this species would be during the nesting season. Project activities at the LNG terminal site would begin before the nesting season and would occur between November and February at the Wahkiakum County Sand Pit site. Because streaked horned larks would not be likely to initiate nesting within an active construction site, impacts on nesting activities would not be anticipated.

Western Snowy Plover

Occurrence at the LNG Terminal

A search of the ORNHIC and PHS databases found no western snowy plover nest site records within a 2-mile search radius of the proposed LNG terminal. Although potential nesting habitat for the western snowy plover exists on dredge spoil areas at the LNG terminal, the nearest known nesting location is over 150 miles south of the LNG terminal site.

Critical Habitat

The nearest critical habitat unit to the proposed LNG terminal is WA-4, which is located about 40 miles northwest in Pacific County, Washington (64 Federal Register 68507 – 68544).

Impacts and Mitigation

Given the lack of observations of this species in the vicinity, it is unlikely that the western snowy plover would be affected by construction or operation of the LNG terminal.

Kincaid's Lupine

Occurrence at the LNG Terminal

The ORNHIC has no record of Kincaid's lupine within a 2-mile radius of the proposed LNG terminal. Although potentially suitable habitat for Kincaid's lupine is present at the LNG terminal site within the grassy openings that are interspersed in upland scrub-shrub habitat, a botanical survey conducted by NorthernStar in June 2006 did not identify Kincaid's lupine in areas that would be disturbed by project activities. However, the FWS raised concerns regarding terrestrial habitat survey methods in

their April 20, 2007 letter to the FERC requesting additional information for the BA and EFH Assessment. To confirm that listed endangered or threatened plants do not occur in the project area and would not likely be adversely affected by project activities, **we recommend that:**

- **Prior to construction of the LNG terminal and pipeline facilities, NorthernStar should conduct additional botanical surveys, where necessary, for federally listed endangered and threatened plants in the appropriate habitats within the project area during the appropriate survey period. Before the initiation of surveys, NorthernStar should consult with the FWS for appropriate survey methods and periods for each species. If project facilities are not constructed within 1 year from the date of issuance of authorizations, NorthernStar should consult with the appropriate offices of the FWS to update the species list and to determine if additional surveys are required. The survey reports and any FWS comments on the survey and its conclusions should be filed with the Secretary. The survey reports should include the following information:**
 - a. **name(s) and qualifications of the person(s) conducting the survey;**
 - b. **method(s) used to conduct the survey;**
 - c. **date(s) of the survey;**
 - d. **area surveyed (include the mileposts surveyed); and**
 - e. **proposed mitigation measures that would substantially minimize or avoid potential impacts on listed endangered or threatened plants found in the project area.**

NorthernStar must receive written approval from the Director of OEP before implementing any mitigation measures.

Critical Habitat

Critical habitat has not been designated for Kincaid's lupine. However, critical habitat was proposed for this species in 2005 (70 Federal Register 66491 – 66599). The nearest proposed critical habitat unit for this species is located in Lewis County, Washington, which is approximately 30 miles northeast of the proposed LNG terminal site.

Impacts and Mitigation

Because there are no known occurrences of Kincaid's lupine in the vicinity of the LNG terminal and the nearest proposed critical habitat unit for Kincaid's lupine is located approximately 30 miles northeast of the LNG terminal, with the implementation of our recommendation to complete any necessary follow-up surveys, it is unlikely that Kincaid's lupine would be affected by construction or operation of the LNG terminal.

Water Howellia

Occurrence at the LNG Terminal

The ORNHIC has no record of water howellia within a 2-mile radius of the proposed LNG terminal. Although potentially suitable habitat for water howellia is present at the LNG terminal site, water howellia was not identified during a botanical survey conducted by NorthernStar in June 2006 in areas that would be disturbed by project activities. However, the FWS raised concerns regarding terrestrial habitat survey methods in their April 20, 2007 letter to the FERC requesting additional information for the BA and EFH Assessment. Therefore, we have recommended that NorthernStar conduct additional botanical surveys for federally listed endangered and threatened plants in the appropriate habitats within the project area during the appropriate survey period (see *Kincaid's lupine*).

Critical Habitat

Critical habitat has not been designated for water howellia.

Impacts and Mitigation

Because there are no known occurrences of water howellia in the vicinity of the LNG terminal, and with the implementation of our recommendation to complete any necessary follow-up surveys, it is unlikely that water howellia would be affected by construction or operation of the LNG terminal.

State Listed Threatened and Endangered Species

NorthernStar consulted with the ODFW, ORNHIC, WDFW, and WNHP to identify state listed endangered and threatened species with the potential to occur at the LNG terminal. Many state listed endangered or threatened species are also federally listed and were previously described. The remaining species (bald eagle) is discussed below.

Bald Eagle

During field visits to the proposed LNG terminal site, eagles were observed flying over the area near the proposed LNG terminal site; however no bald eagle nests occur within 0.5 mile of the proposed LNG terminal. The WDFW has also mapped bald eagle communal winter roost sites, which may be found along the Columbia River in the vicinity of the proposed LNG terminal and are most likely to be occupied from November through March.

Breeding bald eagles could potentially be affected by construction and operation of the proposed LNG terminal if nest trees and surrounding habitat are removed, or if construction were to occur in the vicinity of an active nest or communal roost. Indirect impacts on bald eagles could include short-term displacement of aquatic prey populations due to in-water activities, increased visual and auditory construction disturbance, and potentially increased suspended sediment and turbidity levels. Displacement of aquatic prey could indirectly affect bald eagles that may utilize these species as a portion of their diet. In addition, increased noise and other physical disturbances associated with operation of the LNG terminal could temporarily cause bald eagles to avoid the area.

To minimize impacts on bald eagles before and during construction and operation of the LNG terminal, NorthernStar has agreed to implement the following measures:

- Review the most recent Isaacs and Anthony annual bald eagle nesting survey database for current nest locations. This document is generally available each December; however, current nesting season activity can usually be obtained by contacting Frank Isaacs directly. Direct contact would be made to access data before each construction season to update new nest locations.
- Minimize construction, operation, and maintenance activities within 0.5 mile of any nest (or 0.25 mile if any nest is within line-of-sight of the project), or to non-breeding season (October 31 to December 31).
- Avoid removal of potentially suitable bald eagle nest or roost trees (e.g., mature deciduous or coniferous trees that offer an unobstructed view of the surrounding area).
- Restore large areas of estuarine habitat suitable for salmonid rearing, and other measures that would increase fish production and ecosystem health in the lower Columbia River area.

To minimize impacts on bald eagles before and during construction of the project, **we recommend that:**

- **NorthernStar should conduct a survey for bald eagles, where necessary, prior to construction of the LNG terminal and pipeline facilities. Before the initiation of surveys, NorthernStar should consult with the FWS, ODFW, and WDFW for appropriate survey methods and periods for the surveys. The survey reports and any agency comments on the survey and its conclusions should be filed with the Secretary. The survey reports should include the following information:**
 - a. **name(s) and qualifications of the person(s) conducting the survey;**
 - b. **method(s) used to conduct the survey;**
 - c. **date(s) of the survey;**
 - d. **area surveyed (include the mileposts surveyed); and**
 - e. **proposed mitigation measures that would substantially minimize or avoid potential impacts on bald eagles found in the project area.**

NorthernStar must receive written approval from the Director of OEP before implementing any mitigation measures.

Other Special Status Species

Sensitive Species

In addition to the species listed under the ESA or by the States of Oregon and Washington, five species that are candidates for listing as endangered or threatened or species of special concern have been identified by the agencies as having the potential to occur in the vicinity of the proposed LNG terminal. The ODFW also expressed concerns regarding several other sensitive species, including the coastal cutthroat trout, red-legged frog, American peregrine falcon, and olive-sided flycatcher. The NMFS requested analysis of the North American green sturgeon. These sensitive species are discussed below.

Coastal Cutthroat Trout

Potential spawning habitat for coastal cutthroat trout exists in the portion of Hunt Creek below the falls. In addition, the mouth of Hunt Creek and main channel of the Columbia River likely provide habitat for coastal cutthroat trout. Potential impacts resulting from construction and operation of the proposed LNG terminal on coastal cutthroat trout would be similar to those discussed previously concerning federally listed salmonids. As discussed in section 4.5.2.1, NorthernStar would implement various mitigation measures to avoid, minimize, rectify, reduce, and/or compensate for impacts on salmonids; these measures would also benefit coastal cutthroat trout.

Eulachon

The WDFW expressed concern about potential impacts on eulachon spawning in the mainstem Columbia River and out-migration of smelt larvae as a result of construction and operation of the proposed LNG terminal. Potential impacts on eulachon would be similar to those discussed previously concerning federally listed salmonids. Research by the WDFW and ODFW has lead to recommendations that dredging and disposal of dredged material be prohibited in the Columbia River between CRM 35 and CRM 75 from March through June, which is the key spawning and post spawning periods for eulachon. The established ODFW in-water work window for the Columbia River (November 1 through February 28) implements these recommendations. A discussion of additional measures to avoid, minimize, rectify, reduce, and/or compensate for impacts on aquatic resources is included in section 4.5.2.1.

Lampreys

Based on general requirements for spawning habitat, potential spawning habitat for the Pacific lamprey exists below the falls on Hunt Creek. In addition, estuarine and fluvial environments at the mouth of Hunt Creek and within the main channel of the Columbia River may provide bottom habitat for juvenile lampreys. The mainstem Columbia River also serves as a migratory route for adults moving to or returning from the sea. Potential impacts resulting from construction and operation of the proposed LNG terminal on lampreys would be similar to those discussed previously concerning federally listed salmonids. As discussed in section 4.5.2.1, NorthernStar would implement various mitigation measures to avoid, minimize, rectify, reduce, and/or compensate impacts on salmonids; these measures would also benefit river and Pacific lampreys.

North American Green Sturgeon

Potential impacts resulting from construction and operation of the proposed LNG terminal on North American green sturgeon would be similar to those discussed previously concerning federally listed salmonids. As discussed in section 4.5.2.1, NorthernStar would implement various mitigation measures to avoid, minimize, rectify, reduce, and/or compensate for impacts on salmonids; these measures would also benefit North American green sturgeon.

Red-legged Frog

There is potential for the red-legged frog to occur in wetlands and waterbodies in the vicinity of the proposed LNG terminal. Potential impacts on aquatic species as a result of construction and operation of the proposed LNG terminal are discussed in section 4.5.2.1. Due to the presence of hundreds of red-legged frogs on lower Svensen Island, preservation of existing habitat and restoration of additional habitat on lower and middle Svensen Island would mitigate for any impacts on potential red-legged frog habitat lost at the LNG terminal site.

American Peregrine Falcon

Suitable habitat for the American peregrine falcon is located immediately east of the LNG terminal on basalt cliffs that border the western bank of the Columbia River. American peregrine falcons have been observed during site visits flying over the bluffs located immediately south of the LNG terminal. The ORNHIC database has one record of an active nest from this area, which is about 0.8 mile east of the LNG terminal. Given the distance and the location of the potential nesting habitat, it is unlikely that the American peregrine falcon would be adversely impacted by construction or operation of the LNG terminal.

Northern Goshawk

Forests in the vicinity of the proposed LNG terminal site are relatively young and generally lack characteristics that contribute to nesting, foraging, and roosting habitats for northern goshawks. Marginally suitable late-successional habitat for this species is limited to a narrow fringe of mature conifers that occurs on the bluffs just upstream of the LNG terminal. The ORNHIC database does not have any records of this species occurring within 5 miles of the LNG terminal site. Significant impacts on northern goshawks from construction and operation of the proposed LNG terminal would not be anticipated.

Olive-sided Flycatcher

The olive-sided flycatcher has been recorded on both of the Breeding Bird Surveys conducted near the LNG terminal site (Sauer et al., 2005). Construction and operation of the LNG terminal could potentially affect the olive-sided flycatcher due to clearing of forested habitats. Potential impacts and proposed mitigation for clearing of forested habitat are discussed in section 4.4.2.2. Migratory birds are discussed below (see *Migratory Bird Treaty Act*).

Purple Martin

A study conducted in 1998 to determine distribution, abundance, and nest site characteristics of purple martins in Oregon found that martins were locally common along the Columbia River, in some coastal estuaries, and at the Fern Ridge Reservoir (Hovarth, 1999). Purple martins have been documented on nearby river islands, and they were observed flying over the proposed LNG terminal site during a site visit in early August 2005 (ORNHIC, 2006). Potentially suitable nesting habitat for this species is present within the project area in the form of abandoned pilings. However, construction activities at the LNG terminal site would begin during the recommended in-water window (November 1 – February 28), which concludes before purple martins return to the west coast from their wintering grounds in South America. Therefore, disturbance to purple martins nesting at the LNG terminal site would not occur. To mitigate for the permanent loss of potential nesting habitat, NorthernStar proposes to install purple martin gourds at the Peterson Point and Middle Svensen Island Mitigation Sites.

Marine Mammals

As described above, both California sea lions and Pacific harbor seals are expected to occur within the Columbia River near the LNG terminal site regularly. California sea lions occur in the lower Columbia River between September and mid-June, but do not have any haulout sites in the vicinity of the proposed LNG terminal. California sea lions would travel through the project area enroute to foraging areas at Bonneville Dam and Willamette Falls where salmon congregate at these restriction points. As part of dedicated hazing efforts to discourage pinnipeds from foraging on salmon at the dam, observers have documented between 30 California sea lions at the dam (in 2002) to as many as 106 individuals (in 2003).

In contrast, harbor seals have six haulouts within 10 miles of the proposed LNG terminal site and would be expected to occur near the LNG terminal on a more regular basis during the in-water work window. Harbor seals arrive at Bonneville Dam as early as August 28 (in 2007); therefore, occurrence within the Columbia River upstream of the South Jetty could occur as early as August. However, larger numbers of harbor seals would be expected during their seasonal movements into the Columbia River between January and April (Jeffries, 2008).

Jeffries et al. (2000) documented pinniped haulouts along the lower Columbia River, including six haulout sites within 10 river miles of the proposed terminal site. These sites are predominantly or solely used by Pacific harbor seals. At the time of the survey, approximately 1,800 harbor seals were counted at these six haulout sites. Because specific foraging areas for each of the haulouts within 10 miles of the terminal are not known to exist, it is expected that harbor seals using these haulouts would likely forage near the LNG terminal site.

As described above (see *Steller Sea Lion*), it is possible that pinnipeds could be adversely impacted by dredging and pile-driving activities at the LNG terminal. NorthernStar proposes to implement protective measures including the establishment of safety, buffer, and impact zones to protect the Steller sea lion during construction activities at the LNG terminal (see *Steller Sea Lion*). To provide similar protections to other pinnipeds potentially occurring in the vicinity of the LNG terminal, **we recommend that:**

- **NorthernStar should expand the protective measures that would be used to avoid or minimize impacts on Steller sea lions during construction of the LNG terminal (e.g., safety, buffer, and noise impact zones) to include all pinnipeds.**

In addition, because of the potential that pile driving may be carried out if pinnipeds are present in the Safety Zone (i.e., the animals may be exposed to sound pressures in excess of 160 dB), NorthernStar has stated that it intends to obtain an Incidental Harassment Authorization, in consultation with the NMFS before beginning pile driving activities

Migratory Bird Treaty Act

As described in section 4.5.2.3, habitat modification, increased noise levels, terminal lighting, and vegetative clearing associated with construction and operation of the proposed LNG terminal could adversely affect migratory birds occurring in the vicinity of the LNG terminal. Although the LNG terminal would be located within a portion of the Columbia River estuary that provides important stop-over habitat for migrating birds, it is anticipated that adequate habitat is located in the vicinity of the LNG terminal to accommodate birds displaced by habitat modification and increased noise levels. In addition, restoration and preservation at the proposed mitigation sites would also provide new or enhanced areas of bird habitat.

Potential impacts on wildlife (including migratory birds) due to terminal lighting are discussed in sections 4.5.2.1 and 4.5.2.3. Due to the presence of high-quality habitats that are frequently used by shorebirds, waterfowl, and other waterbirds migrating along the Pacific Flyway, additional measures are necessary to minimize impacts from terminal lighting on migratory birds in the vicinity of the proposed project. Therefore, we have recommended in section 4.5.2.1 that NorthernStar continue to consult with the NMFS, FWS, ODFW, and other applicable agencies to finalize its Lighting Plan.

To minimize impacts on migratory birds from vegetative clearing, NorthernStar has stated that it would avoid clearing during peak nesting season and would clear for vegetation maintenance only between mid-July and October. However, due to the importance of the area for migratory birds,

additional measures are necessary to minimize impacts on nesting birds due to construction of the LNG terminal. Therefore, **we recommend that:**

- **NorthernStar should consult with the FWS and other appropriate agencies to develop a Migratory Bird Nest Avoidance Plan to minimize impacts on migratory birds during the peak nesting season. NorthernStar should file its Migratory Bird Nest Avoidance Plan along with agency comments with the Secretary prior to the commencement of clearing activities at the LNG terminal and along the pipeline.**

4.6.2.3 Pipeline Facilities

Federally Listed Species

Salmonids

Lower Columbia River Chinook Salmon ESU

Occurrence along the Pipeline Route – Lower Columbia River Chinook salmon ESU occur in the following waterbodies crossed by the proposed pipeline route: Westport Slough, Clatskanie River, Columbia River, Cameron Creek, Abernathy Creek, Germany Creek, Cowlitz River, and Ostrander Creek (ODFW, 2005; Wade, 2000, 2002). These waterbodies provide habitat for migrating spring- and fall-run adults from March to June and August to October, respectively (NMFS, 2005c). Spring-run salmon out-migrate as yearlings during the spring and summer. In contrast, fall-run salmon out-migrate as sub-yearlings from April through June (NMFS, 2005c). Juvenile rearing for both spring- and fall-run populations occurs within these waterbodies throughout the year (ODFW, 2005; Wade, 2000, 2002).

Critical Habitat – Within the waterbodies crossed by the proposed pipeline route, the Lower Columbia River Chinook salmon ESU has designated critical habitat (migratory corridor PCE) within the lower Columbia River mainstem. As described in section 4.6.2.1, adult salmon from this ESU migrate through the lower Columbia River en route to their spawning grounds in upstream and smolts out-migrate through the lower Columbia River. In addition, critical habitat (spawning PCE) has been designated at the proposed crossings of the Columbia River, Abernathy Creek, Germany Creek, and Ostrander Creek. Finally, critical habitat (rearing PCE) has been designated within nearshore habitats of the Columbia River mainstem, Columbia River islands, and the accessible low gradient reaches of Columbia River floodplain sloughs, Hunt Creek, Westport Slough, Clatskanie River, Cameron Creek, Abernathy Creek, Germany Creek, Cowlitz River, and Ostrander Creek (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation.

Upper Columbia River Spring-run Chinook Salmon ESU

Occurrence along the Pipeline Route – Occurrence of the Upper Columbia River Spring-run Chinook salmon ESU within waterbodies crossed by the proposed pipeline route would be limited to seasonal migrations within the lower Columbia River. The life stages present and seasonal occurrence of the Upper Columbia River Spring-run Chinook Salmon ESU along the lower Columbia River are described in section 4.6.2.1.

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated as critical habitat (rearing and migratory corridor PCEs) for the Upper Columbia River Spring-run Chinook salmon ESU (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation.

Upper Willamette River Chinook Salmon ESU

Occurrence along the Pipeline Route – Upper Willamette River Chinook salmon occur in the following waterbodies crossed by the proposed pipeline route: Westport Slough; Columbia River; and the tidal reaches of the Clatskanie River, Abernathy Creek, Germany Creek, and Cowlitz River (ODFW, 2005; Kostow, 1995). The Columbia River provides habitat for migrating adults between April and May, with a peak in mid-May, (NMFS, 2005c). According to the Biological Review Team (2005), out-migration has been found to occur in recently emerged juveniles during the winter through early spring, in sub-yearlings during the fall through early winter, and as yearlings in the late winter through spring (NMFS, 2005c). In addition, juvenile sub-yearling Chinook salmon from the Upper Willamette River Chinook salmon ESU rear over-winter in nearshore habitats, of the Columbia River mainstem, Westport Slough, and the tidal reaches of the Clatskanie River, Abernathy Creek, Germany Creek, and the Cowlitz River, after juveniles emerge between February and June (NMFS, 2005c).

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated as critical habitat (rearing and migratory corridor PCEs) for the Upper Willamette River Chinook salmon ESU (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation.

Snake River Spring/Summer-run Chinook Salmon ESU

Occurrence along the Pipeline Route – Occurrence of the Snake River Spring/Summer-run Chinook salmon ESU within waterbodies crossed by the proposed pipeline route would be limited to seasonal migrations within the lower Columbia River. The life stages present and seasonal occurrence of the Snake River Spring/Summer-run Chinook salmon ESU along the lower Columbia River are described in section 4.6.2.1.

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated critical habitat (migratory corridor PCE) for the Snake River Spring/Summer-run Chinook salmon ESU (58 Federal Register 68543 – 68554). Adjacent riparian zones are included in the designation, defined as those areas within 300 feet of the normal line of high water of a stream channel.

Snake River Fall-run Chinook Salmon ESU

Occurrence along the Pipeline Route – Snake River Fall-run Chinook salmon occur in the following waterbodies crossed by the proposed pipeline route: Westport Slough; Columbia River; and the tidal reaches of the Clatskanie River, Abernathy Creek, Germany Creek, and Cowlitz River (ODFW, 2005; Kostow, 1995). As described in section 4.6.2.1, the Columbia River provides habitat for migrating adults between August and December and for out-migrating smolts between April and June (Bell Fisheries Handbook, 1973). In addition, juvenile sub-yearling Chinook salmon from the Snake River Fall-run Chinook salmon ESU rear in nearshore habitats of the Columbia River mainstem, Westport Slough, and the tidal reaches of the Clatskanie River, Abernathy Creek, Germany Creek, and the Cowlitz River for up to 1 year before out-migrating (Bell Fisheries Handbook, 1973).

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated as critical habitat (rearing and migratory corridor PCEs) for the Snake River Fall-run Chinook salmon ESU. Adjacent riparian zones are included in the designation, defined as those areas within 300 feet of the normal line of high water of a stream channel.

Columbia River Chum Salmon ESU

Occurrence along the Pipeline Route – Columbia River chum salmon occur in the following waterbodies crossed by the proposed pipeline route: Westport Slough; Columbia River; and the tidal reaches of the Clatskanie River, Abernathy Creek, Germany Creek, and the Cowlitz River (Ehlke and Keller, 2002). Chum salmon populations in tributaries crossed by the proposed pipeline route in Oregon are extirpated and the few fish observed in these tributaries are strays from runs returning to Washington tributaries of the lower Columbia River (ODFW, 2005). The Columbia River, Abernathy Creek, Germany Creek, and the Cowlitz River provide habitat for migrating and spawning adults between mid-October and December and for out-migrating smolts between March and May, with a peak from mid-April through early May (NMFS, 2005c). In addition, out-migrating smolts from Washington tributaries of the lower Columbia River and spawning areas in the Columbia River upstream of the project area rear in nearshore habitat of the Columbia River mainstem and the tidal reaches of the Clatskanie River, Abernathy Creek, Germany Creek, and the Cowlitz River between December and May (Bell Fisheries Handbook, 1973).

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated as critical habitat (rearing, migratory corridor, and spawning PCEs) for the Columbia River chum salmon ESU (70 Federal Register 52630 – 52858). In addition, critical habitat (rearing and migratory corridor PCEs) has been designated at the proposed crossings of Abernathy Creek, Germany Creek, and the Cowlitz River (70 Federal Register 52630 – 52858). The designation defines the lateral extent of critical habitat for each designated stream reach as the width of the stream channel as defined by its bankfull elevation.

Lower Columbia River Coho Salmon ESU

Occurrence along the Pipeline Route – The Columbia River coho salmon ESU may occur in the following waterbodies crossed by the proposed pipeline route: Westport Slough, Clatskanie River, Columbia River, Cameron Creek, Abernathy Creek, Germany Creek, Tributary 5 to Coal Creek, Coal Creek, Cowlitz River, Ostrander Creek, and Ostrander Creek Tributary 1 (ODFW, 2005; Good et al., 2005; Wade, 2000, 2002). Within the waterbodies listed above, adult migration occurs between June and February, smolt out-migration occurs between April and August, and juvenile rearing occurs throughout the year (ODFW, 2005; Good et al., 2005; Wade, 2000, 2002).

Critical Habitat – Critical habitat has not been designated for the Lower Columbia River coho salmon ESU.

Snake River Sockeye Salmon ESU

Occurrence along the Pipeline Route – Occurrence of the Snake River sockeye salmon ESU within waterbodies crossed by the proposed pipeline route would be limited to seasonal migrations within the lower Columbia River. The life stages present and seasonal occurrence of the Snake River sockeye salmon ESU along the lower Columbia River are described in section 4.6.2.1.

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated critical habitat (migratory corridor PCE) for the Snake River sockeye salmon ESU (58 Federal Register 68543 – 68554). Critical habitat includes the adjacent riparian zone defined as those areas within 300 feet of the normal line of high water of a stream channel; therefore, the log pond at the LNG terminal is included in the critical habitat designation.

Lower Columbia River Steelhead DPS

Occurrence along the Pipeline Route – The Lower Columbia River steelhead DPS may occur in the following waterbodies crossed by the proposed pipeline route: the Columbia River, the Cowlitz River, Ostrander Creek, and Tributary 1 to Ostrander Creek (Wade, 2000, 2002). Due to the variability in the lifecycle of steelhead, adult migration within the waterbodies listed above occurs throughout the year, with seasonal peaks in activity; smolts out-migrate between March and June, with a peak in April or May; and juvenile rearing occurs throughout the year (Wade, 2000, 2002; NMFS, 2005c).

Critical Habitat – Within the waterbodies crossed by the proposed pipeline route, critical habitat (rearing and migratory corridor PCEs) has been designated for the Lower Columbia River steelhead DPS in the Columbia River, the Cowlitz River, and Ostrander Creek (70 Federal Register 52630 – 52858). The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Middle Columbia River Steelhead DPS

Occurrence along the Pipeline Route – Occurrence of the Middle Columbia River steelhead DPS within waterbodies crossed by the proposed pipeline would be limited to migration within the lower Columbia River. As described in section 4.6.2.1, the lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity, and out-migrating smolts between March and June (NMFS, 2005c).

Critical Habitat – As described in section 4.6.2.1, the Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Middle Columbia River steelhead DPS (70 Federal Register 52630 – 52858). The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Upper Columbia River Steelhead DPS

Occurrence along the Pipeline Route – Occurrence of the Upper Columbia River steelhead DPS within waterbodies crossed by the proposed pipeline route would be limited to migration within the lower Columbia River. As described in section 4.6.2.1, the lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity, and out-migrating smolts between March and June (Bell Fisheries Handbook, 1973).

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Upper Columbia River steelhead DPS (70 Federal Register 52630 – 52858). The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Upper Willamette River Steelhead DPS

Occurrence along the Pipeline Route – Occurrence of the Upper Willamette River steelhead DPS within waterbodies crossed by the proposed pipeline route would be limited to migration within the lower Columbia River. As described in section 4.6.2.1, the lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity, and out-migrating smolts between March and July (Bell Fisheries Handbook, 1973).

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Upper Willamette River steelhead DPS (70 Federal Register 52630 – 52858). The

lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Snake River Basin Steelhead DPS

Occurrence along the Pipeline Route – Occurrence of the Snake River Basin steelhead DPS within the waterbodies crossed by the proposed pipeline route would be limited to migration within the lower Columbia River. As described in section 4.6.2.1, the lower Columbia River provides habitat for migrating adults throughout the year, with seasonal peaks in activity, and out-migrating smolts between March and June (Bell Fisheries Handbook, 1973).

Critical Habitat – The Columbia River is designated critical habitat (rearing and migratory corridor PCEs) for the Snake River Basin steelhead DPS (70 Federal Register 52630 – 52858). The lateral extent of critical habitat for each designated stream reach is the width of the stream channel as defined by its bankfull elevation.

Impacts and Mitigation

The pipeline facilities associated with the Bradwood Landing Project would affect federally listed salmonids and sturgeon and/or their designated critical habitat through various activities including:

- in-water pipeline construction;
- terrestrial/riparian habitat modification associated with construction;
- accidental spills and leaks of hazardous materials; and
- maintenance vegetation clearing.

Potential impacts and mitigation from each of these factors are summarized in table 4.6.2-1 and discussed in detail in section 4.5.3.1. The FERC received numerous comments stating that the mitigation proposed by NorthernStar does not adequately compensate for impacts on aquatic resources associated with the project. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. To ensure that the mitigation proposed for the Bradwood Landing Project adequately compensates for project-related impacts, we have recommended that NorthernStar continue to consult with the appropriate natural resource agencies to finalize its Compensatory Mitigation Plan. The final Compensatory Mitigation Plan would be filed along with agency comments and applicable approvals with the Secretary prior to construction of the project.

Columbian White-tailed Deer

Occurrence along the Pipeline Route

During the investigation for this project, biologists observed Columbian white-tailed deer from the Oregon lowlands subpopulation along the proposed pipeline route at commercial poplar plantations between Westport Slough and the Clatskanie River. Within the known range of the Oregon lowlands subpopulation, the proposed pipeline would cross lands designated by the FWS as Essential Habitat for the Columbian white-tailed deer between MPs 5.3 and 7.1. Essential Habitat is also located within 0.5 mile of the pipeline between MP 10.5 and MP 13.7 (FWS and the Columbian White-tailed Deer Recovery Team, 1983).

Critical Habitat

Critical habitat has not been designated for the Columbian white-tailed deer.

Impacts and Mitigation

Potential impacts on Columbian white-tailed deer from construction and operation of the proposed pipeline include habitat modification and increased noise and disturbances. These impacts are discussed below.

Habitat Modification – About 178.5 acres of potentially suitable habitat for the Columbian white-tailed deer would be temporarily impacted by construction of the pipeline facilities within areas known to support Columbian white-tailed deer. In general, impacts on Columbian white-tailed deer habitat would occur between MPs 4 and 19 of the proposed route. Potentially suitable habitats for Columbian white-tailed deer along the proposed pipeline route are categorized as forest (coniferous, deciduous, mixed, riparian, and early seral forests as well as forested wetlands), scrub shrub (upland scrub-shrub and palustrine scrub-shrub wetland), and herbaceous (pastures, open fields, commercial poplar plantations and palustrine emergent wetlands). These habitats are discussed below.

Within areas known to support Columbian white-tailed deer, construction and operation of the proposed pipeline would impact about 31.6 acres of forested habitats (24.0 acres temporary removal and 7.6 acres permanent removal). Of this, 21.3 acres (14.9 acres temporary removal and 6.4 acres permanent removal) consist of commercially managed coniferous forest, which would likely be harvested within 5 to 15 years. Due to the location of these habitats in the hills above the LNG terminal site, these habitats provide only marginally suitable habitat for Columbian white-tailed deer, which prefer lowland habitats.

In addition, about 32.0 acres (22.4 acres temporary removal and 9.6 acres permanent removal) of designated essential habitat would be affected due to removal of forested vegetation within construction right-of-way and extra work areas. Most of the essential habitat within the proposed pipeline route consists of young hybrid poplar plantations (classified as palustrine emergent wetlands), with lesser amounts of pastures/open fields, riparian forest, and emergent wetlands. Columbian white-tailed deer have been observed using commercial poplar plantations where it occurs along the proposed pipeline route between the communities of Westport and Port Westward.

Removal of forested habitats could temporarily reduce cover and forage opportunities for Columbian white-tailed deer or lead to displacement into adjacent habitats. As described in section 4.4.2.3, upland forested habitats would be replanted in-kind with trees, with the exception of the portion of the right-of-way within 15 feet of the pipeline (30 feet total), and forested wetlands would be replanted in-kind with trees, with the exception of the portion of the right-of-way within 5 feet of the pipeline (10 feet total), thereby minimizing the extent of disturbance. NorthernStar's proposed tree planting exceeds the revegetation requirements of the FERC staff's Plan and Procedures. The corridor centered on the pipeline would be planted with a native grass seed mix and maintained in an herbaceous state to facilitate maintenance and inspection. Nearly complete canopy coverage over the pipeline would be expected to develop in most areas within approximately 20 years. The resulting corridor of herbaceous corridor could provide potential foraging or movement habitat for Columbian white-tailed deer.

About 9.6 acres of scrub-shrub habitats (all temporary) within areas known to support Columbian white-tailed deer would be impacted by construction and operation of the proposed pipeline. These habitats may provide suitable fawning, resting, and foraging habitat. As described above, the recovery time for impacts on scrub-shrub habitats would be significantly less than that required in forested habitats. With the exception of the herbaceous corridor centered on the pipeline, scrub-shrub habitats would be expected to recover to preconstruction conditions within 3 to 5 years.

In addition, 137.4 acres of herbaceous habitats (99.6 acres temporary removal and 37.8 acres permanent removal) would be affected by construction of the proposed pipeline within areas known to

support Columbian white-tailed deer. Due to the early successional stage of these habitats, they would be expected to recover very quickly from construction-related disturbance. Fields cleared early in the growing season may recover by the end of the growing season; whereas, fields cleared later in the growing season would be expected to recover the following spring.

During construction of the pipeline, Columbian white-tailed deer may avoid or abandon areas within about 1,000 feet of active work sites (U.S. Department of the Interior, 2007). During the first 2 to 4 weeks of life, fawns rely entirely on remaining motionless to avoid predators. Therefore, if construction activities were to occur during this period, fawns would be vulnerable to being crushed by construction vehicles. Furthermore, fawns need to nurse between five and six times per day. Because Columbian white-tailed deer would be expected to avoid or abandon areas within 1,000 feet of construction activities, fawns hidden near construction areas would not likely be nursed for the entire length of time each day that activities occurred, which could negatively impact their survival. To minimize disturbances to Columbian white-tailed deer, NorthernStar has stated that ground disturbing activities in suitable Columbian white-tailed deer habitat would be scheduled outside of the fawning season where possible. However, because fawns are highly vulnerable during the fawning season, the U.S. Department of the Interior recommended that no construction activities of any kind occur between MPs 4 and 19 during the fawning season. In order to provide the protection requested by the U.S. Department of the Interior, **we recommend that:**

- **Pipeline construction activities should not occur within potential habitat for Columbian white-tailed deer (MPs 4 to 19) between June 1 and July 15.**

Maintenance vegetation clearing along the pipeline route would be conducted between August 1 and April 15, thus avoiding the fawning season.

NorthernStar would compensate for habitat impacts through enhancing and protecting suitable habitats at the Peterson Point Mitigation Site, an area used extensively by the Oregon lowlands subpopulation of Columbian white-tailed deer. The FERC received numerous comments stating that the mitigation proposed by NorthernStar does not adequately compensate for impacts associated with the project. As described in section 2.1.5, NorthernStar is currently revising its Compensatory Mitigation Plan. To ensure that the mitigation proposed for the Bradwood Landing Project adequately compensates for project-related impacts, we have recommended that NorthernStar continue to consult with the appropriate natural resource agencies to finalize its Compensatory Mitigation Plan. The final Compensatory Mitigation Plan would be filed along with agency comments and applicable approvals with the Secretary prior to construction of the project.

Increased Noise and Disturbances – Increased noise and physical disturbances associated with construction and operation of the proposed pipeline and associated facilities could adversely affect Columbian white-tailed deer by disruption of foraging and resting behaviors, and temporary displacement in response to construction disturbance if this species is present during construction. Pipeline maintenance would result in periodic increases in noise and other physical disturbances; however, NorthernStar would schedule ground disturbing activities in suitable Columbian white-tailed deer habitat outside of the fawning season where possible.

Marbled Murrelet

Occurrence along the Pipeline Route

The PHS and ORNHIC have no records of the marbled murrelet within 2 miles of the proposed pipeline route (ORNHIC, 2004 and 2006). Forests in the vicinity of the proposed pipeline are relatively

young and generally lack characteristics that contribute to nesting habitats, foraging, and roosting areas for marbled murrelets.

Critical Habitat

Within the counties crossed by the Bradwood Landing pipeline, critical habitat units for the marbled murrelet have been designated within Clatsop County, Oregon and Cowlitz County, Washington. The closest critical habitat unit to the Bradwood Landing pipeline is in Clatsop County about 0.4 mile southwest of MP 2.5 (FWS, 1996a).

Impacts and Mitigation

As described in section 4.6.2.2, in its April 20, 2007 letter to the FERC, the FWS commented that suitable nesting habitat for the marbled murrelet may occur in several locations within the project area. A total of 21.6 acres of potentially suitable habitat for marbled murrelets occurs within areas impacted by the proposed pipeline. Of this, 12.5 acres would be permanently converted to herbaceous habitat. Specifically, approximately 3.3 acres of category 2 coniferous forest (based on the State of Oregon's HMP) would be permanently impacted by the proposed pipeline in Oregon. In addition, construction and operation of the proposed pipeline in Washington would impact about 12.2 acres of high quality coniferous forest habitats (6.1 acres would be permanent), 5.8 acres of high quality mixed forest habitats (2.9 acres would be permanent), and 0.3 acre of high quality riparian forest habitats (0.2 acre would be permanent).

Within areas of potentially suitable habitat, the FWS recommended that unless there are documented reasons to conclude that nesting is not occurring, NorthernStar should conduct surveys to determine the nesting status of marbled murrelets in the project area. In response to this letter, NorthernStar has stated that it will conduct field investigations to confirm that potentially suitable habitat occurs in the project area. If suitable habitat is identified, NorthernStar would either conduct surveys to determine presence of marbled murrelets or would simply assume presence in the project area.

If present, marbled murrelets could potentially be affected by construction of the proposed pipeline if nest trees and surrounding habitat were to be removed, or if construction were to occur in the vicinity of an active nest. Indirect impacts could include short-term avoidance of foraging habitat and increased visual and auditory disturbance due to construction activities. As noted previously, the FERC staff is currently revising its BA and EFH Assessment for the Bradwood Landing Project, which will be resubmitted to the FWS with a request to initiate formal consultation in compliance with section 7 of the ESA. Additional analysis of the potential for occurrence of and potential impacts on marbled murrelets in the vicinity of pipeline facilities will be included in the revised BA and EFH Assessment. The FERC would not allow construction of the project to proceed until after we have completed formal consultation.

Northern Spotted Owl

Occurrence along the Pipeline Route

A search of the ORNHIC and PHS databases found no northern spotted owl nest site records within a 2-mile search radius of the proposed project area. The nearest known active spotted owl nest is located between 3 and 4 miles south of the LNG terminal in the Clatsop State Forest (ORNHIC, 2006). Forests in the vicinity of the proposed pipeline route are relatively young and generally lack characteristics that contribute to nesting habitats, foraging, and roosting areas for spotted owls.

Critical Habitat

Within the counties crossed by the Bradwood Landing pipeline, critical habitat for the northern spotted owl has been designated in Cowlitz County, Washington. The closest critical habitat unit to the proposed pipeline route is WA-39 (FWS, 1992b), located about 24.4 miles east of the pipeline interconnect with the Williams Northwest pipeline system in eastern Cowlitz County (FWS, 1992b).

Impacts and Mitigation

Because there are no known occurrences of northern spotted owls in the vicinity of the proposed pipeline route, and the distance to the nearest critical habitat unit is over 20 miles, it is unlikely that northern spotted owls would be affected by construction or operation of the proposed pipeline.

Kincaid's Lupine

Occurrence along the Pipeline Route

The ORNHIC has no record of Kincaid's lupine within a 2-mile radius of the proposed pipeline route and there is little habitat that is potentially suitable for this species in the project area. Additionally, a botanical survey of the project area conducted by biologists contracted by NorthernStar did not identify Kincaid's lupine in the project area. Because the FWS raised concerns regarding terrestrial habitat survey methods in their April 20, 2007 letter to the FERC and the botanical survey report prepared for this project did not clearly confirm that all areas of potential habitat were surveyed during appropriate survey periods, we have recommended NorthernStar complete additional consultations with the FWS and conduct additional surveys, as necessary (see section 4.6.2.2).

Critical Habitat

Critical habitat has not been designated for Kincaid's lupine. However, critical habitat was proposed for this species in 2005 (70 Federal Register 66491 – 66599). The nearest proposed critical habitat unit for this species is located in Lewis County, Washington, which is over 20 miles north of MP 22.

Impacts and Mitigation

Because there are no known occurrences of Kincaid's lupine in the vicinity of the pipeline route and the nearest proposed critical habitat unit for Kincaid's lupine is located over 20 miles north of MP 22, with the implementation of our recommendation to complete any necessary follow-up surveys, it is unlikely that Kincaid's lupine would be affected by construction or operation of the proposed pipeline.

Nelson's Checker-mallow

Occurrence along the Pipeline Route

The ORNHIC has no record of Nelson's checker-mallow occurring within 2 miles of the project facilities. Additionally, a botanical survey of the project area conducted by NorthernStar in June 2006 did not identify Nelson's checker-mallow in the project area. However, Nelson's checker-mallow has been documented near Coal Creek Road in Cowlitz County. According to WNHP data, the Coal Creek site was first discovered in 1990 and contains two subpopulations: the northern subpopulation and the southern subpopulation. The northern subpopulation is located near the junction of Carlon Loop Road and Coal Creek Road and contains over 100 plants in a patchy distribution. The southern subpopulation

is located east of Carlon Loop Road and occupies an area approximately 10 feet by 15 feet in size. The northern subpopulation is located outside of the proposed pipeline alignment and is not likely to be impacted by construction of the proposed project. However, based on WNHP data, the southern subpopulation occurs within the proposed pipeline alignment near MP 28.0.

The southern subpopulation was not seen in a cursory look by the WNHP in 2006 (Arnett, 2006). In addition, another pipeline was installed in this location in 1992, after the last documented siting. However, based on concerns raised by the FWS, NorthernStar conducted additional surveys for Nelson's checker-mallow in June and July 2007. No Nelson's checker-mallow plants were observed at or around the pipeline crossing near Coal Creek (the historic southern subpopulation). The location of the historic southern population is now an actively grazed horse pasture, with a parcel to the south that undergoes regular herbicide spraying. However, at least 15 Nelson's checker-mallow plants were observed at the historic northern subpopulation, approximately 0.5 miles north of the pipeline right-of-way at MP 28.0.

Critical Habitat

Critical habitat has not been designated for Nelson's checker-mallow.

Impacts and Mitigation

As described above, the southern subpopulation of Nelson's checker-mallow was documented within the proposed project area near MP 28.0 in 1991, but not during surveys in 2007. Since this species has the ability to tolerate disturbances such as regular mowing and some ground disturbance, botanical surveys would be conducted prior to ground disturbing activities in the vicinity of the southern subpopulation. If the species is present, NorthernStar has stated that the area would be identified and protective fencing would be erected prior to construction and for the duration of all ground disturbing activities. If no rare plant species are found, no special precautions would be warranted. Furthermore, NorthernStar proposes to install the pipeline near the southern subpopulation of Nelson's checker-mallow using the HDD or conventional bore method. Therefore, impacts on the southern subpopulation of Nelson's checker-mallow due to construction of the proposed pipeline are not anticipated. Because the HDD method would be used to install the proposed pipeline, maintenance vegetative clearing would be avoided; therefore impacts on the southern subpopulation of Nelson's checker-mallow during operation of the pipeline are not anticipated.

Because there are no other known occurrences of Nelson's checker-mallow in the vicinity of the proposed pipeline, with the implementation of our recommendation to complete any necessary follow-up surveys, impacts on Nelson's checker-mallow due to construction or operation of the pipeline are not anticipated.

Water Howellia

Occurrence along the Pipeline Route

The FWS conducted extensive searches in Oregon but failed to locate water howellia; therefore, it is thought to be extirpated from the state (FWS, 1996b). Mincemoyer (2005) provided 18 records for populations of water howellia in western Washington. The ORNHIC and PHS databases had no record of water howellia within a 2-mile-radius search area of the proposed pipeline route. This species is not documented within the project area. Field surveys conducted in June 2006 determined that potential habitat for water howellia is located within the project area along the proposed pipeline route but did not identify any occurrences of water howellia in the project area. Because the FWS raised concerns regarding terrestrial habitat survey methods in their April 20, 2007 letter to the FERC and the botanical

survey report prepared for this project did not clearly confirm that all areas of potential habitat were surveyed during appropriate survey periods, we have recommended NorthernStar complete additional consultations with the FWS and conduct additional surveys, as necessary (see section 4.6.2.2).

Critical Habitat

Critical habitat has not been designated for water howellia.

Impacts and Mitigation

Because there are no known occurrences of water howellia in the vicinity of the pipeline route, with the implementation of our recommendation to complete any necessary follow-up surveys, it is unlikely that water howellia would be affected by construction or operation of the proposed pipeline.

State Listed Threatened and Endangered Species

NorthernStar consulted with the ODFW, ORNHIC, WDFW, and WNHP to identify state-listed endangered and threatened species with the potential to occur along the proposed pipeline route. Many state listed endangered or threatened species are also federally listed; these species were discussed previously (see *Pipeline Facilities, Federally Listed Species*). The remaining state listed threatened or endangered species are discussed below.

Western Pond Turtle

The western pond turtle has been extirpated from most of its former range in Washington, but two known populations remain in the Columbia River Gorge. Potentially suitable habitat for this species is found along the pipeline route where it crosses wetlands, sloughs, and other open water areas. However, little or no suitable upland nesting habitat is present as these areas are often densely vegetated. The ORNHIC had no records of occurrence for this species within 5 miles of the pipeline route in Oregon. With implementation of NorthernStar's SWPPP, the potential to impact the western pond turtle or its habitats would be minimal.

Bald Eagle

Bald eagle nesting, foraging, and wintering areas are known to occur within all counties affected by the proposed project in the form of mature riparian forested and upland forested habitats. Isaacs and Anthony (2005) identified five bald eagle nests within 0.5 mile of the proposed pipeline. The closest documented bald eagle nest site is approximately 0.4 mile from the proposed pipeline route near Abernathy Creek in Cowlitz County, Washington (Isaacs and Anthony, 2005). This nest site is located downstream of the Abernathy Creek crossing in heavy coniferous forest habitat. Other nest sites are located 0.5 mile from the proposed pipeline at Crims Island, Poysky Slough, Poysky Island, and Wallace Island in Columbia County, Oregon (Isaacs and Anthony, 2005). The Poysky Slough nest site is located in a stand of mature cottonwoods adjacent to a dike access road and a commercial poplar farm. The Poysky Island site was first documented in 2005 and successfully fledged two eaglets that year. During field visits to the proposed LNG terminal site and pipeline route, eagles were observed flying over the area near the proposed LNG terminal site as well as over Abernathy Creek. The WDFW has also mapped bald eagle communal winter roost sites. Such sites may be found along all of the major waterbodies crossed by the project and are most likely to be occupied from November through March.

Breeding bald eagles could potentially be affected by pipeline activities if nest trees and surrounding habitat are removed, or if construction were to occur in the vicinity of an active nest or

communal roost. The FWS (2007c) developed the *National Bald Eagle Management Guidelines* to help increase and maintain bald eagle populations by protecting important nesting and communal roosting habitat while allowing for flexibility in accommodating site-specific conditions. These guidelines call for preserving communal roost, nest, and important foraging sites; maintaining natural forested (or vegetative) buffers around nest trees; and avoiding certain activities during the nesting and roosting periods. When construction activities are within line-of-site of an active nest site, the FWS recommends maintaining a 660-foot buffer to minimize visual and auditory effects. Nests, nest trees, and habitat immediately surrounding the nest tree should not be removed at any time of the year.

Indirect impacts on bald eagles could include increased visual and auditory construction disturbance. Displacement of aquatic prey could indirectly affect bald eagles that may utilize these species as a portion of their diet. In addition, increased noise and other physical disturbances associated with construction and operation of the proposed pipeline, could temporarily cause bald eagles to avoid the area. Measures proposed by NorthernStar to minimize impacts on bald eagles before and during construction and operation of the project are discussed in section 4.6.2.2

Western Wahoo

During botanical surveys, a western wahoo population was found at the Abernathy Creek pipeline crossing in Cowlitz County, Washington (near MP 21.1). The pipeline would be installed using the HDD method at this waterbody, which would avoid disturbance of this species. Furthermore, NorthernStar would install a fence around the site to avoid any inadvertent impacts on the western wahoo plants during pipeline construction.

Other Special Status Species

Sensitive Species

In addition to the species listed under the ESA or by the States of Oregon and Washington, four species that are candidates for listing as endangered or threatened or species of special concern have been identified by state agencies as having the potential to occur in the vicinity of the proposed pipeline. The ODFW also expressed concerns regarding several other sensitive species, including the coastal cutthroat trout, red-legged frog, tailed frog, western painted turtle, American peregrine falcon, and olive-sided flycatcher. These sensitive species are discussed below.

Coastal Cutthroat Trout

Potential habitat for coastal cutthroat trout occurs along the proposed pipeline route in the main channel of the Columbia River. NorthernStar proposes to install the pipeline beneath the Columbia River using the HDD method. Therefore, any impacts on coastal cutthroat trout would be avoided unless a frac-out occurs or an HDD borehole is unsuccessful. As discussed in section 4.5.3.1, NorthernStar would implement various mitigation measures to avoid, minimize, rectify, reduce, and/or compensate impacts on salmonids; these measures would also benefit coastal cutthroat trout. Therefore, impacts on coastal cutthroat trout as a result of construction and operation of the proposed pipeline would not be significant.

Eulachon

The WDFW expressed concern about potential impacts on eulachon larvae as they migrate down the Columbia River to the Pacific Ocean. NorthernStar proposes to install the pipeline beneath the Columbia River using the HDD method. Therefore, any impacts on eulachon would be avoided unless a frac-out occurs or an HDD borehole is unsuccessful. As discussed in section 4.5.3.1, NorthernStar would

implement various mitigation measures to avoid, minimize, rectify, reduce, and/or compensate impacts on salmonids; these measures would also benefit eulachon. Therefore, impacts on eulachon as a result of construction and operation of the proposed pipeline would not be significant.

Lampreys

Potential bottom habitat for juvenile lamprey occurs within the main channel of the Columbia River. The mainstem Columbia River also serves as a migratory route for adults moving to or returning from the sea. NorthernStar proposes to install the pipeline beneath the Columbia River using the HDD method. Therefore, any impacts on lampreys would be avoided unless a frac-out occurs or an HDD borehole is unsuccessful. As discussed in section 4.5.3.1, NorthernStar would implement various mitigation measures to avoid, minimize, rectify, reduce, and/or compensate impacts on salmonids; these measures would also benefit lampreys. Therefore, significant impacts on lamprey as a result of construction and operation of the proposed pipeline are not anticipated.

Columbia Torrent (seep) Salamander

Potentially suitable habitat for this species is found at stream crossings along the proposed pipeline route. Project-related disturbances at many of the significant stream crossings would be avoided through the use of the HDD method (see section 4.3.2.4). With implementation of NorthernStar's ESC Plans and SWPPP, the potential to impact the Columbia torrent salamander or its habitats would be minimal.

Red-legged Frog

Potential habitat for the red-legged frog occurs in wetlands and waterbodies along the proposed pipeline route. Potential impacts and mitigation for waterbody crossings on aquatic species are discussed in section 4.5.3.1. Hundreds of red-legged frogs have been reported on lower Svensen Island. Restoration and preservation of lower Svensen Island would mitigate for any significant impacts on red-legged frogs or their habitats along the proposed pipeline route.

Tailed Frog

Potentially suitable habitat for tailed frogs exists within cold, shallow waterbodies crossed by the proposed pipeline route. Potential impacts and mitigation for waterbody crossings on aquatic species are discussed in section 4.5.3.1.

Western Painted Turtle

The western painted turtle could potentially occur along the proposed pipeline route in emergent wetlands and shallow waterbodies. Potential impacts and mitigation for waterbody crossings on aquatic species are discussed in section 4.5.3.1.

Townsend's Big-eared Bat

Potentially suitable foraging habitat for this species may occur along the pipeline route. However, preferred roosting habitat for the Townsend's big-eared bat does not occur in the project area. In addition, the ORNHIC had no record of this species within 5 miles of the pipeline route in Oregon. As part of its Mitigation Plan, NorthernStar proposes to enhance potential bat habitat by installing bat houses at the Peterson Point Mitigation Site. Therefore, we have determined that construction and operation of

the Bradwood Landing Project is not likely to result in significant impacts on the Townsend's big-eared bat.

American Peregrine Falcon

American peregrine falcons have been observed during site visits flying over potentially suitable habitat bordering the western bank of the Columbia River near MP 2.0. The ORNHIC database has one record of an active nest from this area, which is about 0.8 mile east of the pipeline origin at the LNG terminal. Given the distance and the location of the potential nesting habitat, it is not likely that the American peregrine falcon would be adversely impacted by construction or operation of the proposed pipeline.

Olive-sided Flycatcher

The olive-sided flycatcher has been recorded on both of the Breeding Bird Surveys conducted near the proposed pipeline route (Sauer et al., 2005). Construction and operation of the proposed pipeline could potentially affect the olive-sided flycatcher due to clearing of forested habitats. Potential impacts and proposed mitigation for clearing of forested habitat are discussed in section 4.4.2.3. Migratory birds are discussed below (see *Migratory Bird Treaty Act*).

Migratory Bird Treaty Act

During construction and operation of the proposed pipeline, habitat modification, increased noise and lighting, and vegetative clearing could adversely affect migratory birds occurring along the pipeline route. Potential impacts on terrestrial wildlife, including migratory birds, due to habitat modification as well as increased noise and lighting are discussed in section 4.5.2.3. In order to minimize potential impacts, NorthernStar has stated that vegetative clearing along the pipeline route would be conducted between August 1 and April 15, thus avoiding the peak nesting season. However, due to the importance of the area for migratory birds, additional measures are necessary to minimize impacts on nesting birds due construction and maintenance clearing along the pipeline route. Therefore, we recommended in section 4.6.2.2 that NorthernStar consult with the FWS and other appropriate agencies to develop a Migratory Bird Nest Avoidance Plan to minimize impacts on migratory birds during the peak nesting season.

4.6.3 Conclusions and Recommendations for Threatened, Endangered, and Other Special Status Species

As described above, informal consultations with the FWS and NMFS have identified 37 federally listed species as potentially occurring in the general vicinity of the Bradwood Landing Project. In addition, California sea lions and Pacific harbor seals transit past and utilize haulout sites upstream from the LNG terminal site. The Columbia River estuary is also one of the most important sites on the Pacific Flyway for migratory birds. Finally, although no longer listed under the ESA, the bald eagle is federally protected under the Bald and Golden Eagle Protection Act and the Migratory Bird Treaty Act. Under both laws, the disturbance of eagles, their nests, and eggs is prohibited.

A variety of measures have been proposed by NorthernStar that would avoid or minimize environmental impacts on threatened, endangered, and other special status species. These measures include:

- reducing the size of the LNG terminal footprint to avoid or minimize impacts on wetlands and Hunt Creek;

- routing the power line to avoid impacts on late-successional forest habitats;
- routing the pipeline to avoid or minimize impacts on sensitive environmental features and/or habitats;
- extensive use of the HDD or bore technique during construction of the pipeline to avoid or minimize disturbance of sensitive habitats, including waterbodies containing sensitive aquatic species or habitats;
- minimizing potential water quality impacts by using erosion control measures;
- restoring temporary construction work areas by implementing appropriate restoration and revegetation techniques;
- replanting forested habitats with in-kind tree specimens, with the exception of the portion of the right-of-way within 5 feet of the pipeline (10 feet total), thereby minimizing the extent of disturbance;
- controlling the spread of noxious and/or invasive plants;
- selecting larger than normal diameter pilings for the LNG carrier berth and unloading facilities;
- driving all piles vertically within a bubble-filled caisson to minimize acoustic impacts on aquatic species (thus minimizing the number of piles and the length of pile driving activities);
- providing screened water intakes at the LNG terminal to provide cooling and ballast water to the LNG carriers while unloading to minimize entrainment and impingement of juvenile fish; and
- minimizing the amount of water drawn from the Columbia River by filling LNG carrier ballast tanks with the same water used to cool the engines (thus also minimizing the discharge of warm water into the Columbia River).

Additionally, NorthernStar has proposed compensatory mitigation that provides new or enhanced areas of aquatic and wildlife habitats. Moreover, NorthernStar's voluntary implementation of its SEI has the potential to provide significant benefits to salmonids and the lower Columbia River ecosystem (see section 4.6.2.2). In addition to benefiting special status species, these measures would also benefit general wildlife, fisheries, and vegetation in the project area.

Beyond the mitigation proposed by NorthernStar, we have recommended that additional measures be implemented to further reduce potential impacts on protected species, including:

- continue to coordinate with the NMFS, FWS, ODFW, and/or other appropriate agencies regarding the following potential issues:
 - wake stranding of juvenile salmonids;
 - shoreline erosion;

- entrainment and impingement of juvenile salmonids;
- temperature impacts due to discharges at the LNG terminal wharf;
- LNG carrier speed, seasonal, or other restrictions to avoid or minimize impacts on whales;
- development of the final Compensatory Mitigation Plan;
- development of the final Waterbody and Wetland Construction and Mitigation Procedures Plan;
- development of a revised Bubble Curtain Contingency Plan;
- development of a revised Lighting Plan;
- agency consultation during development of a Blasting Management Plan; and
- development of a Migratory Bird Nest Avoidance Plan;
- place nets at the outlet of the log pond that only allow emigration from the pond;
- conduct post-installation water flow mapping through all intake screens at the LNG terminal, and develop and implement a monitoring program to assess the effects of impingement and entrainment from use of the screened water supply system on juvenile salmonids during terminal operations;
- conduct additional botanical surveys for federally listed endangered and threatened plants;
- conduct a survey for bald eagles prior to construction of LNG terminal and pipeline facilities;
- expand the protective measures that would be used to avoid or minimize impacts on Steller sea lions during construction of the LNG terminal to include all pinnipeds;
- avoid pipeline construction activities within potential habitat for Columbian white-tailed deer between June 1 and July 15.

Prior to and throughout construction, NorthernStar would train all personnel on procedures that should be followed to comply with proposed and required environmental mitigation measures.

We have determined that the proposed project may expose pinnipeds to sound pressures above the NMFS's threshold for injury and/or disturbance. Because of the potential impacts from pile driving activities on pinnipeds, NorthernStar has stated that it will apply for an Incidental Harassment Authorization pursuant to MMPA section 101(a)(5)(D).

The findings of effect for federally listed species included in table 4.6.3-1 are based on informal consultations with the FWS and NMFS, completed field surveys, and review of NorthernStar's proposed measures to avoid, minimize, or mitigate impacts on listed species. In compliance with section 7 of the ESA and the MSA, the FERC staff is currently revising its BA and EFH Assessment for the Bradwood Landing Project, which will be resubmitted to the NMFS and FWS with a request to initiate formal consultation.

TABLE 4.6.3-1

**Federally Listed Endangered, Threatened, or Candidate Species Potentially Occurring in the

Based on information included in the revised BA and EFH Assessment developed during the formal consultation process by NorthernStar, the NMFS and FWS will prepare BOs as to whether or not the federal actions associated with this project would likely jeopardize the continued existence of a listed species, or result in the destruction or adverse modification of designated critical habitat; summarize the information on which the opinion is based; and discuss in detail the effects of the project on listed species or designated critical habitat. The BOs may recommend reasonable and prudent measures to be implemented to minimize impacts on specific individuals or habitat and reduce the level of take associated with project activities. In addition, the BOs would include the specific terms and conditions by which the reasonable and prudent measures are to be accomplished. As described above, the FERC would not allow construction of the project until after we have completed formal consultation with the NMFS and FWS. In compliance with the ESA, **we recommend that:**

- **NorthernStar should not begin construction activities at the LNG terminal and the pipeline until:**
 - a. **the staff completes formal consultation with the NMFS and FWS;**
 - b. **NorthernStar completes consultation with the NMFS under section 101(a)(5)(D) of the MMPA; and**
 - c. **NorthernStar has received written notification from the Director of OEP that construction or use of mitigation may begin.**

4.7 LAND USE, RECREATION, AND VISUAL RESOURCES

4.7.1 Waterway for LNG Marine Traffic

4.7.1.1 Land Use

Land use along the shore of the waterway for LNG marine traffic consists primarily of forest. The lower Columbia River is mostly a rural region, with the exception of the urban areas of Cathlamet and Ilwaco in Washington, and Astoria and Warrenton in Oregon. Elsewhere along the shore of the waterway are scattered residences and commercial/industrial locations. On the northern shoreline of the Columbia River from the Long Beach peninsula eastward in Pacific County, Washington are the sparsely populated unincorporated communities of Chinook, McGowan, Megler, and Knappton, and in Wahkiakum County eastward to CRM 38 are Pigeon Bluff, Altoona, Dahlia, Pillar Rock, Brookfield, Rockland, Bayview, and Skamokawa. On the southern shore of the river in Clatsop County, Oregon between Astoria and Bradwood, are the small unincorporated communities of Burnside, Svensen, Knappa, Brownsmead, and Clifton.

During transit to the LNG terminal, the potential exists for an accidental or intentional breach of an LNG carrier resulting in a release of LNG. Being less dense than water, the LNG would float on the surface before vaporizing. As the LNG vaporizes, a vapor cloud may form that is initially heavier than air and may be dispersed by wind. An LNG vapor cloud cannot explode in the open atmosphere, but can burn if ignited. In the unlikely case of an LNG spill and associated pool fire, land uses and associated vegetation adjacent to the shipping route could be impacted. Effects on structures within Zone 1 would be most severe, while buildings within Zone 3 would be less impacted. However, with implementation of the mitigation measures described in the Coast Guard's WSR, an LNG release along the waterway would be highly unlikely and the potential impact on structures would be less than significant.

4.7.1.2 Existing Residences and Planned Developments

Existing Residences

The majority of land along the waterway within the Zones of Concern is rural, with the exception of the Warrenton/Astoria urban areas in Clatsop County, Oregon and the Cathlamet/Puget Island area of Wahkiakum County, Washington. There are about 1,799 housing units in the City of Warrenton, 4,858 housing units in the City of Astoria, and 278 housing units in the City of Cathlamet. There are other scattered residences in the sparsely populated unincorporated communities elsewhere along the waterway overlapped by the Zones of Concern. In Washington along the waterway, Pillar Rock, Rockland, and Bayview are within Zone 1; Altoona, Brookfield, and Skamokawa are within Zone 2; and Pigeon Bluff and Cathlamet are within Zone 3. In Oregon, Hammond and the waterfront areas of Warrenton and Astoria are within Zone 1; portions of Warrenton, and Astoria are in Zone 2; and part of Astoria and Clifton are overlapped by Zone 3. Population along the waterway is discussed in detail in section 4.8.1.1.

Visual impacts from LNG marine traffic passing by existing commercial and residential areas along the waterway would be short term, lasting only minutes within the viewshed. These communities already view thousands of ships traveling up and down the Columbia River.

Residential and commercial areas could be affected by an accidental or intentional breach of an LNG carrier resulting in a release of LNG during transit. In the unlikely event of an LNG release, the effects from a resulting fire would be fairly limited and the fire would be relatively short-lived. Structures within Zone 1 (e.g., along the Astoria waterfront) could be damaged in the event of a pool fire, while structures within Zone 3 would be less affected. However, with implementation of the mitigation measures described in the Coast Guard's WSR, the potential for an LNG release would be extremely unlikely and the potential impacts on residential and commercial areas would be less than significant.

Planned Developments

Based on conversations with the affected counties and communities, we identified future commercial and residential developments along the waterway to be used by LNG marine traffic for this project (see table 4.12-1). As of November 2006, several ongoing or proposed developments were noted on or near the waterfront of Astoria. Projects that were currently under construction included a restaurant, office, and retail development located at Pier 1; the Red Building renovation to accommodate small shops, banquet and conference facilities, and offices located east of Pier 1; a public park development located at 9th Street that also includes a possible expansion; the Millpond Development to accommodate housing units between 23rd and 29th Streets; and a 93-unit condominium development located East of Pier 39 that also includes a potential expansion. Proposed projects included: a public square located east of Pier 1; a condominium and associated restaurant and retail developments at several locations including Columbia Street, Pier 11, 3rd Street, 7th Street, 14th Street, and 15th Street; a 20-townhouse development on 29th Street that was scheduled to begin construction in summer 2007; an unspecified proposed development located at East Mooring Basin; and a building renovation to accommodate restaurant, office, retail, and boat rental establishments located at Pier 39. Three projects were recently completed, including: the Cannery Pier Hotel located east of Pier 1; a building to accommodate office and residential properties located on 31st Street; and a new subdivision located east of Sewer Lagoon. In addition, the River Theater development to accommodate coffee, art, and theater retail located east of Pier 1 was pending a building permit (Cook, 2006; Johnson, 2006; Larson, 2006; McCoy, 2006).

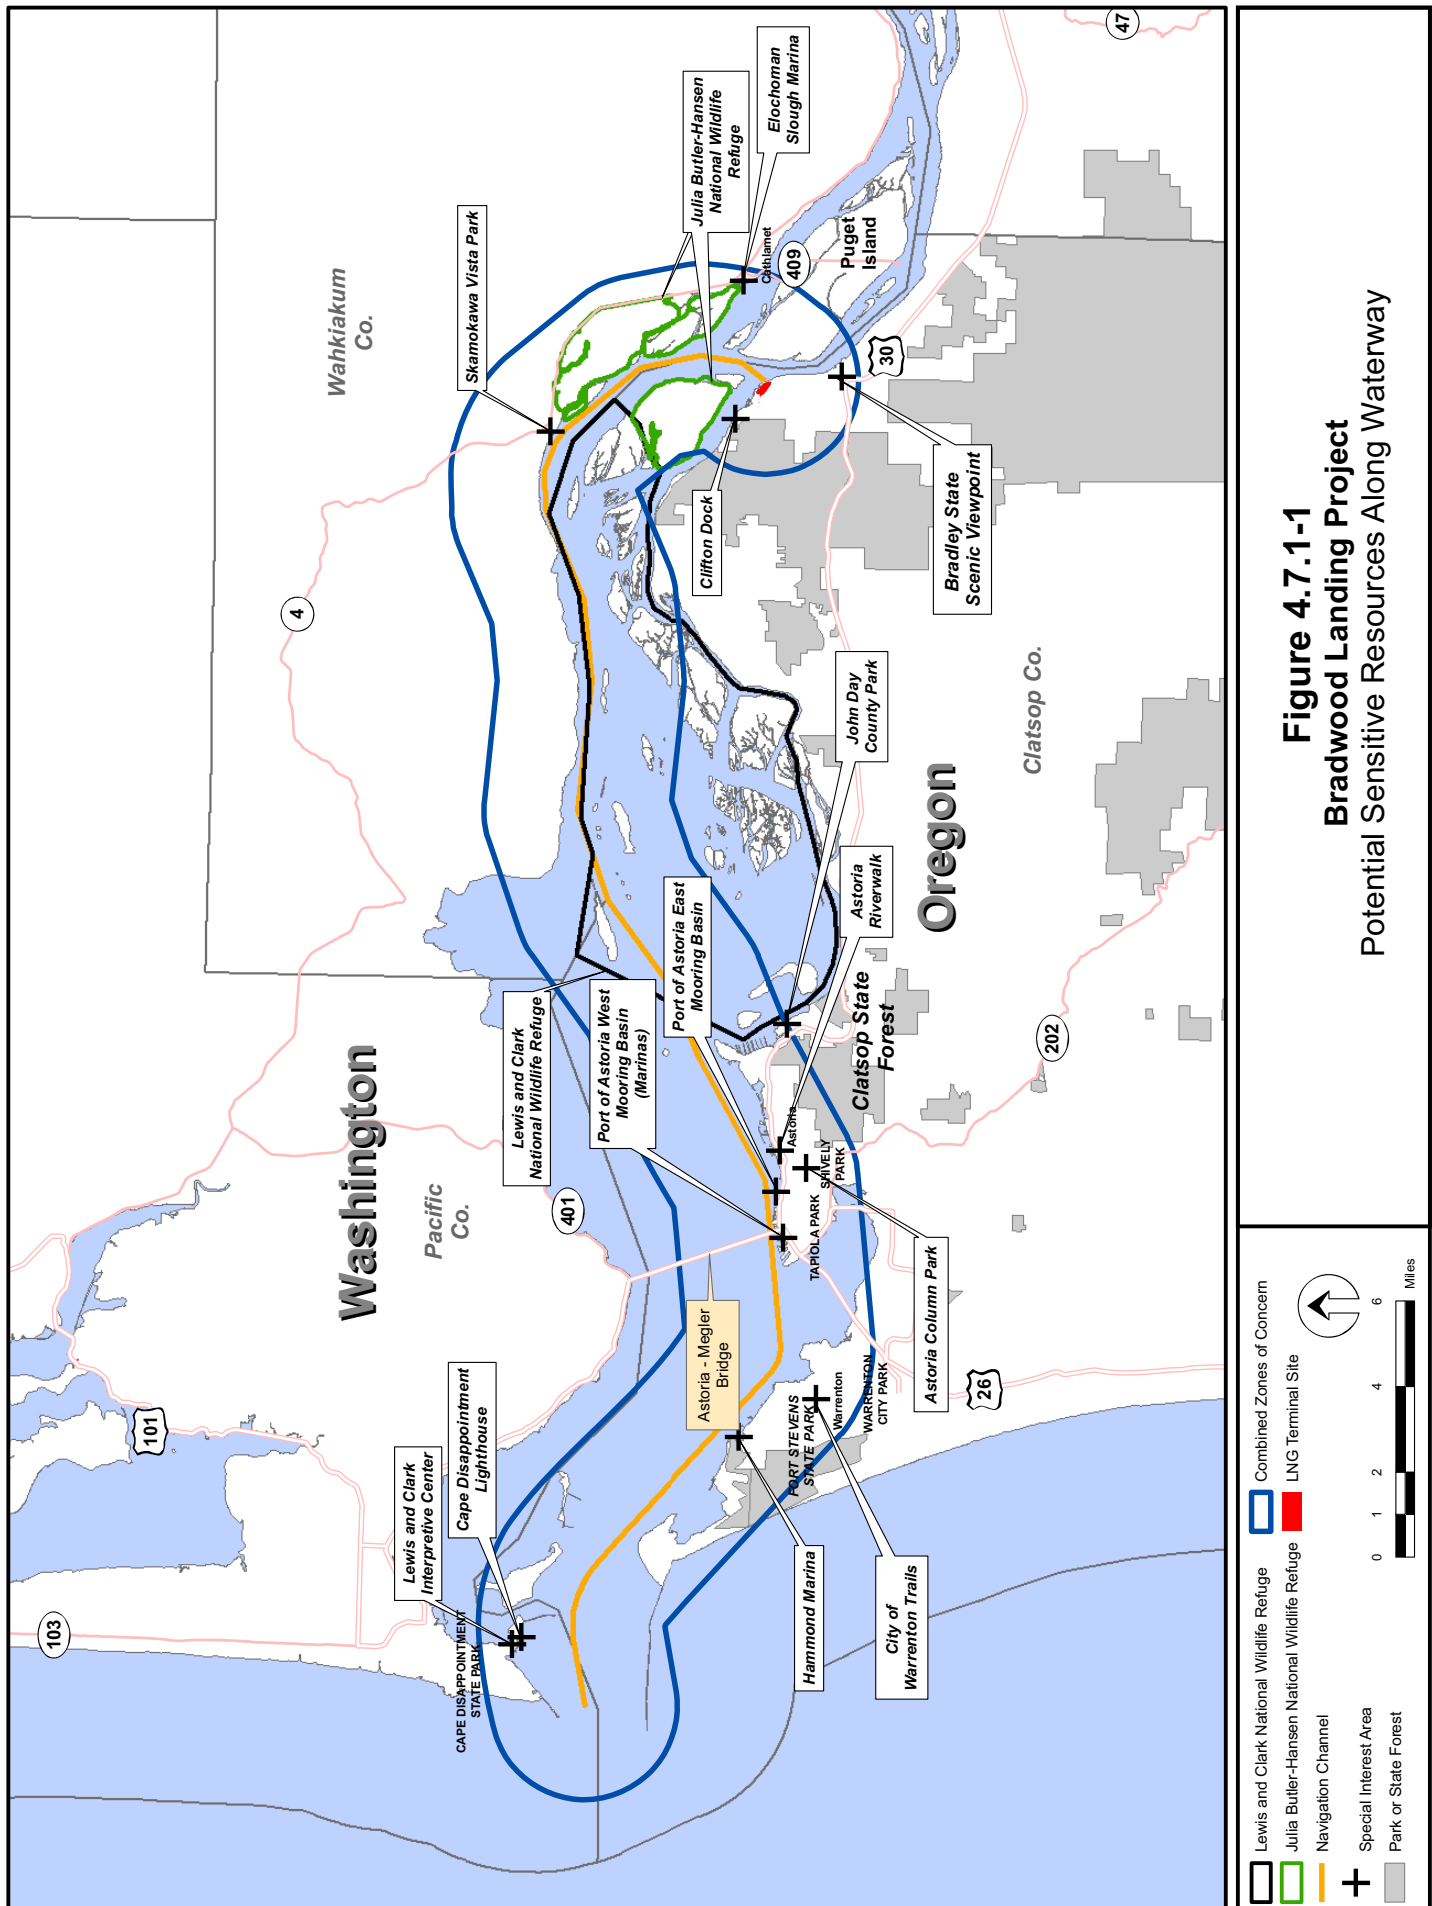

The effects of LNG marine traffic on planned residential and commercial developments along the waterway would primarily be visual. Observers would only see an LNG carrier for a few minutes at any given location as it passes by. Large vessels in the Columbia River are already a common sight within the viewshed for the proposed residential and commercial developments (see section 4.8.1.7). With the implementation of the safety and security measures outlined in the Coast Guard's WSR, it is highly unlikely that there would be a release of LNG from a passing LNG carrier that would lead to a spill and related pool fire, therefore the project should not have any significant impacts on planned commercial or residential developments along the waterway.

4.7.1.3 Coastal Zone Management

Section 4.7.2.4 addresses coastal zone management review for the Bradwood Landing Project.

4.7.1.4 Recreation, Public Interest, and Special Use Areas

A number of recreational and public interest areas are located along the waterway to be used by LNG marine traffic for this project. Potentially sensitive special use areas within the Zones of Concern are shown on figure 4.7.1-1. The potential impacts of LNG marine traffic on recreational sites along the waterway and regional tourism is further discussed in section 4.8.1.8.

Designated Recreation and Public Interest Areas

Lewis and Clark National Historic Trail

The Lewis and Clark National Historic Trail (LCNHT) was authorized by the National Trails System Act of 1978. The trail extends about 3,700 miles, crossing 11 states from Wood River, Illinois to the mouth of the Columbia River, tracing the journey of the Lewis and Clark expedition of 1804-1806. The LCNHT is administered by the National Park Service (NPS), but includes lands in federal, tribal, state, county, local, and private jurisdictions. There are 11 official interpretive centers along the LCNHT, and many other unofficial partnering centers operated by various entities. The NPS headquarters for the LCNHT is in Omaha, Nebraska. The purpose and mission of the LCNHT is to preserve remnants of the historic route of the 1804-1806 Corps of Discovery expedition, provide a comprehensive interpretation of the expedition and the trail, and allow for better public understanding and appreciation of our nation's cultural and natural heritage through opportunities at various locations for visitor enjoyment and use of trail resources (NPS, 2006). We discuss potential project-related impacts on the LCNHT in sections 4.8.1.8 and 4.9 of this EIS.

Lewis and Clark National Historic Park

The Lewis and Clark National Historic Park (LCNHP) is at the western terminus of the LCNHT. Under the umbrella of the NPS, the LCNHP is made up of 12 park sites along the Pacific Coast from Long Beach, Washington to Cannon Beach, Oregon. The LCNHP was created by Congress in 2004, expanding the Fort Clatsop National Memorial, originally established in 1958, by adding other sites at the mouth of the Columbia River related to the Lewis and Clark expedition. The purpose of the LCNHP is to preserve and interpret resources associated with the Corps of Discovery's 1805-1806 winter encampment near the Pacific Ocean at Fort Clatsop. The legislation directed the NPS to work with Oregon and Washington State Parks to promote visitor use and cooperative management (Applegate, et al., 2005). There are two state parks that form a portion of the LCNHP that would be overlapped by the Zones of Concern for LNG marine traffic along the waterway to the Bradwood Landing LNG terminal. These potentially affected elements include Fort Disappointment State Park, which contains the Lewis and Clark Interpretive Center and a memorial to Thomas Jefferson, in Washington, and Fort Stevens State Park in Oregon. The other elements of the LCNHP, including Fort Columbia State Park, Dismal Nitch, and Station Camp in Washington, and Ecola State Park, Sunset Beach State Recreation Area, Fort Clatsop, Fort to Sea Trail, Salt Works, and Netul Landing in Oregon are outside of the Zones of Concern and would not be affected by the project. Potential project related impacts on the LCNHP are discussed in sections 4.8.1.8 and 4.9 of this EIS.

Lower Columbia River Water Trail

The Lower Columbia River Water Trail stretches 146 miles in length from Bonneville Dam to the Pacific Ocean. The water trail is intended for use by people in non-motorized boats, to travel for daily or overnight excursions along the free-flowing portion of the lower Columbia River. There are multiple launches, landings, and campsites located along this segment of the river. The water trail is administered through the Lower Columbia River Water Trail Committee of the Lower Columbia River Estuary Partnership, a non-profit corporation, whose goals include protecting the ecosystem, improving habitat, reducing river pollution, and educating the public. The partnership is attempting to connect the public to the lower Columbia River by promoting the water trail as a valuable resource for recreation, education, and stewardship, and increase access to the river by improving launch and landing sites for non-motorized water craft. The partnership seeks to engage the interest of local counties, communities, businesses, and individuals to support its programs (Lower Columbia River Estuary Partnership, 2007b). The NPS has provided community assistance to this water trail under the Outdoor Recreation Act of 1963. These grants have enabled the Water Trail Committee to inventory more than 70 waypoints along the trail, and

develop an interactive web site to provide paddlers with trail information. The lower Columbia River is divided between the states of Washington and Oregon. The partnership owns no land or facilities along the trail. Instead, the water trail utilizes existing recreational facilities owned and operated by various city, county, or state government agencies. These are discussed further in section 4.8.

Cape Disappointment State Park

Cape Disappointment is a Washington State Park. It encompasses 1,882 acres on the Long Beach peninsula, between the Pacific Ocean and the Columbia River, in Pacific County, Washington. This park is one of the elements of the LCNHP and provides access to the Lower Columbia River Water Trail. Cape Disappointment State Park includes the historic location of Fort Canby, two historic lighthouses (North Head Lighthouse on the Pacific Coast and Cape Disappointment Lighthouse on the Columbia River), the Lewis and Clark Interpretive Center, Thomas Jefferson Memorial, Colbert House Museum, amphitheater, ball fields, boat ramp and dock, 20 picnic tables, campsites and cabins, and 7 miles of hiking trails. The southern portion of the park, including Fort Canby, the Cape Disappointment Lighthouse, and the Lewis and Clark Interpretive Center, is overlapped by Zone 3. Potential project-related impacts on historic elements of the park are discussed in section 4.9.

Fort Stevens State Park

Fort Stevens is an Oregon State Park and an element in the LCNHP. It covers about 3,700 acres at the mouth of the Columbia River, west of Hammond, Oregon, between the Pacific Ocean and Trestle Bay. It is named for the former federal military installation, originally commissioned in 1863, located within its boundaries, and the park includes the remains of gun batteries and the commander's station, and a military museum. Also part of the Fort Stevens State Park, are the remains of the ship wreck of the Peter Iredale, Coffenbury Lake and Swash Lake, wildlife viewing platforms, 9 miles of bike paths, and 5 miles of hiking trails, including the northern trailhead for the Oregon Coast Trail. With 530 campsites, Fort Stevens State Park is the largest public campground of any state park in Oregon. The northern portion of Fort Stevens State Park, including the military museum and Fort Stevens gun batteries, are overlapped by Zone 2.

Lewis and Clark National Wildlife Refuge

The LCNWR is a unit within the system of 547 wildlife refuges nationwide, first established in response to the federal conservation movement by President Theodore Roosevelt in 1903, and operated by the FWS. These refuges offer a network of protected habitats to benefit fish and wildlife, and offer outdoor experiences for the American public. The LCNWR, created in 1971, is meant to preserve wetland habitats along the lower Columbia River estuary and serve as a wintering area for migratory waterfowl and shorebirds. The refuge boundary encompasses 35,000 acres of tidelands and open water, including 8,313 acres of islands and sandbars between CRMs 18.5 and 35 in the Columbia River. It provides nesting areas for about 35 bald eagles, 1,000 tundra swans, 5,000 geese, and 30,000 ducks. The estuary within the LCNWR also offers habitat for fish, seals, otter, beaver, raccoon, weasel, mink, and muskrat. The LCNWR is administered out of the office for the JBHNRW in Cathlamet, has no developed recreational facilities, and the inlands within its boundaries can only be accessed by boat, with launches available at Skamokawa in Washington and John Day Point and Aldrich Point in Oregon. Portions of the LCNWR are overlapped by the Zones 1, 2, and 3.

Julia Butler Hansen National Wildlife Refuge

The JBHNRW was established in 1972 specifically to protect and manage the federally listed endangered Columbian white-tailed deer. The JBHNRW extends from approximate CRM 33.5 to CRM

39 along the Columbia River, and includes the Hunting Islands and Price Island in Washington, and Tenasillahe Island, Crims Island, Wallace Island, and several small parcels in the vicinity of Westport in Oregon. It contains approximately 6,100 acres of pastures, forested tidal swamps, marshes, sloughs, and open water. The JBHNR provides habitat for fish, wintering birds, including bald eagles and osprey, a small herd of Roosevelt elk, and various other mammals, reptiles and amphibians (FWS, 2007b). The islands within the refuge can only be reached by boat. Public recreational facilities within the JBHNR include its headquarters off of Steamboat Slough Road, and the mainland dike road, which is used for vehicle access, public fishing, and wildlife viewing opportunities. Portions of the JBHNR are overlapped by Zones 1, 2, and 3.

Clatsop State Forest

The Clatsop State Forest, comprising some 518,000 acres, is the only public forest in Northwestern Oregon and is administered by the Astoria District of the Oregon Department of Forestry (ODF). According to the ODF (2001), the Clatsop State Forest is 98 percent Board of Forestry Lands. These lands were privately owned and logged between 1910 and 1940, and when Clatsop and Columbia Counties foreclosed due to landowners not paying their taxes, the counties deeded these cutover and unmanaged forest lands to the Board of Forestry to manage as a state forest. The remaining 2 percent of the Clatsop State Forest are Common School Fund Lands. The *Clatsop State Forest Astoria District Recreation Management Plan* outlines the implementation of recreation management in the state forest through objectives and actions, activity zoning, and the type of facilities the ODF will develop and manage. Recreational uses in the Clatsop State Forest occur along roads, rivers, and streams. Recreational activities include hunting, fishing, dispersed or campground camping, off-highway vehicle use, horseback riding, mountain biking, hiking, and scenic viewing (at viewpoints), and some interpretation. Portion of Clatsop State Forest are overlapped by Zone 3 just south and east of the City of Astoria, and to the west of Clifton.

Warrenton/Astoria Parks and Museums

The Warrenton Waterfront Trail and Carruthers Park are overlapped by Zone 2. Within Zone 3 at Warrenton is the Fishermen's Memorial and Lighthouse Park.

Parks in Astoria located within 1,600 meters south of the navigation channel (partly or wholly overlapped by the extent of Zone 2) include Astoria Column, Shively Park, Maritime Park, 4-H fair grounds, Tapiola Park, Warren Field, Fort Astoria, and Fred Lindstrom Memorial Park. The Yacht Club Park is overlapped by Zone 3. The 125-foot-high Astoria Column, dedicated in 1926, is located within a 780-acre wooded park located on Astoria's highest hill. Tapiola Park, established in 1941 by members of the Finnish Brotherhood, includes a skate park in a former swimming pool and an "educational superplayground." Shively Park was developed for Astoria's Centennial celebration in 1911 and designed by Arthur Peck. A small park at 15th and Exchange Streets contains a partial replica of Fort Astoria. Warren Field covers 8 acres. The City of Astoria also operates an Aquatic Center along Marine Drive within Zone 2.

Along the Columbia River waterfront in Astoria, besides the docks, are the Maritime Memorial Park, 6th Street Viewing Dock, 14th Street Riverpark, and the pedestrian/bike Columbia Riverwalk Trail. A restored 1914 trolley runs for 3 miles between Basin and 36th Streets. Portions of these facilities are overlapped by Zone 1. Near the waterfront, within Zone 2, is the 1926 Astoria Victory Monument and Doughboy Statue.

Also situated along Astoria's waterfront is the Columbia River Maritime Museum. Other museums in Astoria, within Zone 2, include the Flavel House in an 1885 Queen Anne Victorian at 8th and

Duane Streets, the Heritage Museum in the old 1904 City Hall building at 16th and Exchange Streets, and the Uppertown Firefighters and Children's Museum in the 1896 North Pacific Brewery building at 30th Street and Marine Drive. The Liberty Theater is in a 1925 Italian Renaissance style building at Commercial and 12th Streets (Astoria and Warrenton Chamber of Commerce, 2007; Astoria's Historic Resources and Heritage, 2006). Astoria's historic resources are addressed in section 4.9.

Skamokawa Vista Park

The 70-acre Skamokawa Vista Park, operated by Wahkiakum Port District No. 2, is located on the north shore of the Columbia River, at about CRM 32, near the mouth of the Skamokawa Creek. The park includes a campground with 34 sites for hookups, playground, game field, and basketball and tennis courts. Additional amenities include picnic tables, toilets, shower, beach, and facilities for small boat launch. It provides access to the Lower Columbia River Water Trail. Skamokawa Vista Park is within Zone 2.

Cathlamet Parks

Within the City of Cathlamet, which is partly overlapped by Zone 3, are two parks and a swimming pool operated by the Department of Parks and Recreation. Erickson Park consists of 10 acres on Columbia Street, acquired in 1947, that includes a covered shelter, and tennis and basketball courts, playground equipment, and nature paths. Strong Park covers about 2 acres on the Cathlamet waterfront and includes the Wahkiakum County Museum (Town of Cathlamet, 2007).

Schools, Libraries, and Hospitals

The Warrenton community library is located within Zone 2. However, all of the public schools in Warrenton appear to be outside of the Zones of Concern.

In Astoria, Captain Robert Gray Elementary School, John Jacob Astor Elementary School, Clatsop Community College, Clatsop Care Center, Columbia Memorial Hospital, Clatsop County Health and Human Services, and the public library are overlapped by Zone 2. Within Zone 3 are Astoria Middle School and Astoria High School. Local infrastructure and public services, including schools and hospitals, for the communities along the waterway used by LNG marine traffic are further discussed in section 4.8.1.6.

Military Installations

The Tongue Point Naval Air Station was established in 1940 on the east side of Astoria, Oregon. In 1964 the Coast Guard Astoria Air Station was located at the Tongue Point Naval Air Station. It was relocated to the Astoria Regional Airport southeast of Warrenton in 1966. However, the Coast Guard maintains an Aid to Navigation Team at Tongue Point and has docking facilities for cutters along the Astoria waterfront. The Coast Guard facility at Tongue Point is overlapped by Zone 2, while the Coast Guard Air Station is within Zone 3. The Coast Guard also operates a life boat station at Cape Disappointment in Ilwaco, Washington, and the mooring for that station is overlapped by Zone 3.

Impacts on Recreation and Public Interest Areas

The main impact on recreation and public interest areas as a result of LNG marine traffic in the waterway would be visual. Visual impacts associated with LNG marine traffic are discussed in section 4.7.1.5.

In the unlikely event of an LNG spill from a tanker in route along the waterway to the terminal, and an associated pool fire, there may be effects upon recreational facilities, parks, and other public interest areas. Those facilities within Zone 1 could sustain damages to structures, features, or vegetation. Facilities within Zone 3 would be less affected. However, with the implementation of the safety and security measures outlined in the Coast Guard's WSR, the chance of a spill would be extremely remote and the potential impacts on recreational facilities, parks, and other public interest areas would be less than significant.

General Recreation and Other River Users

The lower Columbia River is used for both commercial and recreational purposes. Portions of the discussion below are based upon the findings of the *River User Impact Analysis* relative to LNG marine traffic produced for NorthernStar (Kraley, 2006), and NorthernStar's preliminary WSA by ABSG Consulting, Inc.¹⁵ The potential impact of LNG marine traffic in the waterway on commercial and recreational users of the lower Columbia River is further discussed in section 4.8.1.7, and recreation and tourism is also addressed in section 4.8.1.8.

Commercial Uses

Commercial activities along the lower Columbia River include: shipping, commercial fishing, charter boat services, cruises, ship piloting (both along the river and at the bar), tugboat operations and long-shoring, and miscellaneous shore-based activities in the Astoria area. These commercial activities and potential impacts of the Bradwood Landing Project on these activities are further discussed in section 4.8.1.7.

Recreational Uses

Recreational activities for the lower Columbia River and shoreline include: fishing, water-skiing, boating, sailing, kayaking, windsurfing, personal watercraft, sunbathing, sightseeing, wildlife viewing, hiking, camping, picnicking, and beach combing. The potential impact of LNG marine traffic in the waterway on recreation and tourism is further discussed in section 4.8.1.8.

Fishing

Recreational fishing occurs most frequently during the summer months (averaging about 300 private fishing boats in the waters of the Columbia River estuary per day between June and August). The largest fishery on the river, at Buoy 10 near the mouth of the Columbia, is fished during August and accounts for the highest level of recreational boat traffic during that time. According to the ODFW, in 2005 Washington and Oregon anglers combined took over 400,000 fishing trips along the almost 150-mile-long stretch of the lower Columbia River between Bonneville Dam and Buoy 10 (Watts and Takata, 2006).

Boating and Sailing

Recreational boaters, including sport fishers and sailors, can reach the lower Columbia River from upstream boat ramps and marinas, including locations in Kalama and Longview, Washington, and Rainier and Clatskanie, Oregon. Along the waterway to be used by LNG marine traffic in Washington,

¹⁵ The *River User Impact Analysis* was attached as Appendix A to Resource Report 5 in NorthernStar's June 5, 2006 application. It is available for viewing on the FERC Internet website (<http://www.ferc.gov>). Using the "eLibrary" link, select "General Search" from the eLibrary menu and enter the docket number excluding the last three digits in the "Docket Number" field (i.e., CP06-365). Be sure to select an appropriate date range. ABSG Consulting Inc.'s, May 18, 2006, "Waterway Suitability Assessment, Bradwood Landing LNG Project, Columbia River," was submitted to the Coast Guard under its SSI regulations and is not available to the public.

there are boat launches at Cape Disappointment State Park, Chinook, Knappton, and Skamokawa, and moorings at marinas at Ilwaco and Cathlamet. In Clatsop County, Oregon, there are recreational boat ramps at John Day Park, Knappa, Aldrich Point, and Westport, and marinas in Hammond, Warrenton, and Astoria. Both power boats and sailboats can access the lower Columbia River from the boat launches and marinas mentioned above.

Accurate information on the boat traffic into or out of various launches along the lower Columbia River is unavailable, as most rely on the honor system with payment drop boxes based on donations. Therefore, it is not possible to estimate the current level of recreational boat traffic. However, a sense of recreational boating activity can be gauged from the operation of local marinas (see table 4.7.1-1).

TABLE 4.7.1-1			
Marinas and Boat Launches in the Lower Columbia River			
Marina or Boat Launch	County	State	Gross Revenue
Astoria East Mooring Basin	Clatsop	OR	\$90,000
Hammond Marina	Clatsop	OR	\$205,000
Warrenton Marina	Clatsop	OR	\$315,000
Astoria West Mooring Basin	Clatsop	OR	\$310,000
Rainier City Marina	Columbia	OR	\$32,000
Kalama Marina	Cowlitz	WA	\$328,000
Willow Grove Boat Launch	Cowlitz	WA	NA
Cape Disappointment State Park	Pacific	WA	\$170,000
Port of Chinook	Pacific	WA	\$400,000
Port of Ilwaco	Pacific	WA	\$700,000
Elochoman Slough Marina	Wahkiakum	WA	\$433,000
NA	Not available.		

The Hammond Marina, at about CRM 11, includes a four-boat launch ramp, 140 slips, and offers overnight moorage for both commercial and recreational vessels. Facilities include a fuel dock, restroom and showers, picnic area, camping area, and parking lot for 400 vehicles. Two Columbia River Pilot cutters operate out of this marina. The entrance to the Hammond Boat Basin is 1,410 feet from the navigation channel, within Zone 2.

The Warrenton Marina is located up the Skipanon River from the Columbia River navigation channel, but is still overlapped by Zone 3. The marina contains 370 slips, and its facilities include restrooms, showers, and a fish cleaning station (Astoria-Warrenton Chamber of Commerce, 2007). There are an additional 92 slips at the Skipanon Marina.

The Port of Astoria operates two marinas for recreational boaters, overlapped by Zone 1, with moorings for craft up to 100 feet long. The West Basin, located at about CRM 14, contains 335 slips. The East Basin, at about CRM 15.6, has 82 slips, and a public pier, and is home to some of Astoria's fishing fleet (Port of Astoria, 2007). There is also a transient dock at 17th Street.

Water-skiing, Jet-skiing, Windsurfing, and Kayaking

Other recreational uses of the lower Columbia River include water-skiing, personal watercraft such as jet-skis, windsurfing, kite surfing, kayaking and canoeing. Wake-boarding, tubing, and other, similar boat-pulled activities are included in our discussion of water-skiing. Water-skiing and the

mentioned related activities typically occur upriver of CRM 38, where the water is calmer and other boat traffic is relatively sparse.

Windsurfing and kite surfing are relatively recent activities along the lower Columbia River. Most of this activity occurs upriver of CRM 38, with a favorite location being near Clatskanie, Oregon. The Columbia River off of Jones Beach (CRM 47) is known to be used by windsurfers and kite surfers. Windsurfers also use the Columbia River off of Chinook County Park in Pacific County, Washington (CRM 6). However, both Jones Beach and Chinook County Park are located outside of the Zones of Concerns for LNG marine traffic to the proposed Bradwood Landing LNG terminal. Little, if any, windsurfing occurs in the waterway that would be used by LNG marine traffic. Where these activities do take place is typically in shallow areas of the river, near shore, away from the navigation channel. Therefore, we do not expect the project to have any direct impacts on windsurfing or kite surfing activities.

Personal watercraft, such as jet-skis, can be rented in Warrenton, Oregon, and Longview, Washington. This activity can take place in shallower waters, outside of the navigation channel along the lower Columbia River.

Kayaking and canoeing typically occur near the shore and outside of the shipping channel. Kayak rentals are available at several points along the lower Columbia River, including in Warrenton, Oregon and Skamokawa, Cathlamet, and Longview, Washington.

Sunbathing, Beachcombing, Sightseeing, Wildlife Viewing, Hiking, Swimming, Camping, and Picnicking

Increased commercial ship traffic in the lower Columbia River resulting from this project should not have significant negative impacts on sunbathing, beachcombing, sightseeing, wildlife viewing, hiking, swimming, camping, and picnicking. The only developed recreational beach immediately adjacent to the waterway to be used by LNG marine traffic is at Skamokawa Vista Park, at CRM 32, in Wahkiakum County, Washington. Parks and other recreational and public interest areas are discussed above and in section 4.8.1.8. Potential visual impacts from LNG carrier traffic along the river on park and beach users are discussed in section 4.7.1.5. Elsewhere in this EIS are discussions of ship wakes and the potential for shoreline erosion.

Potential Impacts of LNG Marine Traffic in the Waterway on Other River Users

Recreational boaters, including power boat and sailboat users, have always needed to account for commercial ship traffic on the Lower Columbia River. Fishermen frequenting the area indicate that other ship traffic does not represent either a detriment to their fishing experience or to the location they decide to fish (Kraley, 2006). While currently almost 2,000 commercial ships use the lower Columbia River, the project would add about 125 LNG carriers per year to the existing marine traffic. One of the conditions of the Coast Guard's WSR is to impose a moving 500-yard safety and security zone around LNG carriers heading up river. Recreational boat operators may have to move out of that zone while an LNG carrier passes by. We believe this minor inconvenience would only last for a few minutes, as the LNG carriers would travel up river at speeds between 8 and 12 knots. The Coast Guard's WSR further addressed communication networks that would need to be implemented to make other river users aware of future LNG carrier deliveries.

Operators of personal watercraft, such as jet-skis, and kayakers, canoers, and windsurfers typically stay in shallow waters outside of the navigation channel. They may be affected by wakes from LNG carriers. However, large commercial ships that currently travel through the lower Columbia River

already create wakes of similar size to those that would be generated by LNG carriers, and jet-skiers, kayakers, and canoers should be familiar with how to deal with wakes from large ships.

In the unlikely event of an LNG spill and associated pool fire, recreational river users could potentially be affected, depending on the location and duration of the incident. However, with the safety and security measures outlined in the Coast Guard's WSR, the likelihood of such impacts would be extremely remote and the potential impact on recreation river users would be less than significant.

4.7.1.5 Visual Resources

People in Oregon and Washington along the waterway for LNG marine traffic would view LNG carriers on the Columbia River from the point the ships enter the river to the LNG terminal at CRM 38. The proposed LNG terminal is expected to receive approximately 125 LNG carriers per year, averaging 10 to 11 ships per month or one every 3 days. In addition, the Clatsop State Forest has designated Land Management Classifications along the Columbia River just west of the proposed LNG terminal that include the visual focused stewardship subclass. We believe that the visual impacts of LNG marine traffic would be short term, for it would typically take a vessel only a few minutes to pass through the viewshed, traveling at the average speed between 8 and 12 knots. LNG carriers would be generally consistent with large tankers that currently use the navigation channel heading to and from upriver ports. There are as many as 2,000 commercial vessels per year that travel up and down the Columbia River. Therefore, the addition of 125 LNG carriers per year would not be a significant increase in terms of visual impacts for observers along the waterway.

4.7.2 LNG Terminal

4.7.2.1 Land Use

The proposed LNG terminal would be on the southern shore of the Columbia River and southeastern end of the Clifton Channel in Clatsop County, Oregon. NorthernStar controls a 411-acre upland tract, with an option to purchase from the current landowner. Historically, this property was the site of several lumber mills that operated from about 1843 to 1852, 1910 to 1920, and 1930 to 1962, and the location of the town of Bradwood from about 1930 to 1985 (see section 4.9.1.2). Between about 1966 and 2003 the COE placed almost 900,000 cubic yards of material dredged during maintenance of the Columbia River navigation channel at Bradwood.

Construction of the LNG terminal would affect about 61 acres within the 411-acre upland tract controlled by NorthernStar, and about 40 acres would be needed for the permanent operation of the onshore facility structures (see table 4.7.2-1). The remainder of the upland tract to be acquired by NorthernStar would be left alone as a buffer area around the terminal; kept in its current land use as forest, shrub, or wetlands. NorthernStar intends to conserve and improve wetland habitat at the mouth of the Hunt Creek as part of its wetland and habitat mitigation plan. A 58-acre area of the Columbia River would be used for a turning basin and ship berth at the terminal. Within the 58-acre maneuvering area, 46 acres would be dredged from the river bottom that is owned by the state of Oregon (section 1.3 discusses the permits that NorthernStar would need to obtain before being allowed to dredge in the Columbia River). Additionally, a power line would be constructed to bring electricity to the LNG terminal, affecting 16.9 acres. The right-of-way for the power line would be on private land that would have to be acquired by PacificCorp.

TABLE 4.7.2-1												
Land Uses Affected by the Construction and Operation of the Proposed LNG Terminal ^a												
Facility Component	Marine Industrial (acres)		Forest/Aquatic Natural (acres)		Aquatic Development (acres)		Forest (acres)		Aquatic Development/ Aquatic Conservation (acres)		Total (acres)

^a	These were the land use zoning designations at the time NorthernStar filed its applications with the FERC in June 2006. However, in March 2008 Clatsop County changed the zoning for the proposed LNG terminal.											
Con.	Construction											
Oper.	Operation											

The proposed 58-acre ship maneuvering area for the terminal in the Columbia River is currently open water. About 21 acres onshore that would be impacted by construction of the LNG terminal is currently dredged material piles. The onshore area impacted by construction of the LNG terminal is currently forested and scrub-shrub vegetation. Within the onshore area, wetlands characterized as emergent, scrub-shrub, and forested are also present (see table 4.4.1-2). Construction of the 1.5-mile-long powerline would affect forested land. Commercial/industrial lands affected by construction of the proposed LNG terminal would include Bradwood Road and the PWRR. Section 2.1.3 describes the various components of the LNG terminal.

Based on the *Clatsop County Comprehensive Plan*, at the time when NorthernStar filed its applications with the FERC, the land that may be affected by construction and operation of the LNG terminal was zoned as Marine Industrial, Forest, Aquatic Development, Aquatic Natural, and Aquatic Conservation. A DMD Overlay zone applies to a portion of the site. The DMD Overlay Zone is intended to designate sites for disposal of dredged materials. Additionally, an inactive licensed basalt quarry is presently located on the LNG terminal site. The quarry may be activated during construction but would be decommissioned before the LNG terminal is operational.

In response to NorthernStar's land use application to Clatsop County, the zoning for portions of the terminal have been changed. Additional information regarding land use zones at the proposed LNG terminal is provided below in section 4.7.2.2.

4.7.2.2 Consistency with Existing Land Use Plans, Policies, Designations, and Guidelines

State and local government entities in Oregon have established plans, policies, designations, and guidelines for land use development in the project area. At the time NorthernStar filed its applications with the FERC it appeared that the proposed project would not be wholly consistent with some of those plans. However, in March 2008, Clatsop County made a final decision to change the land use zoning at the proposed Bradwood Landing LNG terminal. Consistency of the Bradwood Landing Project with local and state zoning and land use planning goals ordinances, and regulations is discussed below and in section 4.7.3.2. Consistency with coastal zone management programs is discussed in section 4.7.2.4.

Land use in Oregon is required to be consistent with the Statewide Land Use Planning Goals. The goals are implemented in Clatsop County through its state-acknowledged Comprehensive Plan as established by Clatsop County Ordinance 80-14, the Land and Water Development and Use Ordinance (LWDUO). The land uses described in section 4.7.2.1 also equate to the zoning codes used by Clatsop County. These include Marine Industrial, Forest, Aquatic Development, Aquatic Natural, and Aquatic Conservation Two. According to the Comprehensive Plan, the following summarizes the purposes of each of the land use zoning codes affected by the project:

- Marine Industrial – to manage Columbia River Estuary shorelands in urban and urbanizable areas and shorelands in rural areas especially suited for water-dependent development and to reserve these shorelands for water-dependent industrial, commercial, and high-intensity recreational use. The provisions of the Marine Industrial zone are set forth in section 3.620 - 3.636 of the LWDUO.
- Forest 80 – to conserve forest lands by maintaining the county's forest land base; to protect the county's forest economy by making possible economically efficient forest practices that assure the continuous growth and harvest of forest tree species as the leading use of forest land consistent with sound management of soil, air, water, fish and wildlife resources, and scenic resources; and to provide for public and private recreational opportunities and agriculture. The provisions of the Forest 80 zone are set forth in section 3.550 - 3.558 of the LWDUO.
- Aquatic Natural – to assure the preservation and protection of significant fish and wildlife habitats, continued biological productivity of the Columbia River estuarine resources, and scientific research and educational opportunities. These areas are managed to preserve natural resources in recognition of dynamic, natural, geological, and evolutionary processes. This zoning code includes all tidal marshes, tidal flats, and seagrass, algae beds, and ecologically important subtidal areas, and is intended to preserve those natural aquatic resource systems existing relatively free of human influence. Provisions of the Aquatic Natural zone are set forth in section 3.802 - 3.812 of the LWDUO.
- Aquatic Development – to provide for navigation, and other identified needs for public, commercial, and industrial water-dependent uses, consistent with the level of development or alteration allowed by this zone and the need to minimize damage to the Columbia River estuarine ecosystem. Provisions of the Aquatic Development zone are found in section 3.740 - 3.756 of the LWDUO.
- Aquatic Conservation Two – to conserve designated areas of the Columbia River Estuary for long-term uses of renewable resources that do not require major alterations of the estuary, except for the purpose of restoration. These areas are managed for the protection and conservation of their natural resources and benefits, and include areas needed for

maintenance and enhancement of biological productivity, recreational resources, aesthetic values, aquaculture and open water portions of the estuary. Areas that are partially altered and adjacent to existing developments of low to moderate intensity that do not possess the resource characteristics of other aquatic areas are also included in this zone. The provisions of the Aquatic Conservation Two zone are set forth in section 3.780 - 3.792 of the LWDUO.

During project scoping, we received a letter from the Clatsop County Board of Commissioners that further outlined the county's land use regulations and ordinances that apply to the construction and operation of an LNG terminal at Bradwood (Clatsop County Board of Commissioners, 2005). While the letter was not intended to express any position or establish any findings by Clatsop County regarding NorthernStar's proposal, it did identify several apparent conflicts between the existing land use zoning and the action at the time NorthernStar filed its applications with the FERC. Some of the concerns expressed by Clatsop County during scoping are summarized below.

The main policies of Clatsop County's Comprehensive Plan that relate to the LNG terminal are found in the plan's "Goal 16 and 17 Element: Columbia River Estuary." The Goal 16 and 17 Element contains six major policy sections, labeled P15, P20, P21, P30, P40, and P50. Each of these sections contains a detailed set of related policies. For example, P20, "Columbia River Estuary Shoreland and Aquatic Regional Policies," consists of 20 policies dealing with topics such as diking, log storage, and fish and wildlife habitat in the Columbia River estuary. All of Bradwood's shoreline lies within the Columbia River estuary and hence is subject to Goal 16. Therefore, much of the Goal 16 and 17 Element of Clatsop County's plan is relevant to the Bradwood Landing Project. For example, the "use tables" for aquatic and shoreland areas specify categories of development that may be allowed on lands along the Columbia River, including the proposed LNG terminal site. The policies most directly applicable to the proposed development are:

- P20.3, "Deep-Water Navigation, Port and Industrial Development;"
- P20.5, "Dredging and Dredged Material Disposal;"
- P20.6, "Estuarine Construction;" and
- P30.21, "Bradwood."

P30.21 is a three-page subarea plan for the Bradwood area. Some of the key provisions most relevant to the Bradwood Landing Project are as follows:

The Bradwood Industrial site offers limited potential for small to medium water-dependent industrial development. There is deep water close to shore, some available vacant land and the proximity of the wildlife refuge...Future development which would require extensive filling (impacting aquatic areas in excess of 20 acres) along the Columbia River shoreline for the purpose of creating additional industrial land is not appropriate. In order to fully utilize the marine industrial shorelands, it would be appropriate to fill the old Bradwood mill pond. This pond covers an area of less than 10 acres. This fill activity would be subject to the state and federal permit process and the development of proper mitigation areas. An upland area along the entrance road into Bradwood has been identified as a potential mitigation site.

On December 12, 2006, NorthernStar filed an application with Clatsop County to amend the combined Clatsop County Comprehensive Plan Map and Zoning Map to change areas that were zoned as Aquatic Development to Marine Industrial, and from Aquatic Conservation Two to Aquatic Development. In addition, the application sought an amendment to the Clatsop County Comprehensive Plan to allow dredging for the creation of the terminal turning basin and berth, and to delete language in the plan relating to small and medium scaled development. The Clatsop County Planning Commission

held hearings on NorthernStar's land use application in July 2007, and recommended approval of the applications subject to conditions following public deliberations in August 2007, with an adoption of findings on September 28, 2007. The Board of Commissioners held public hearings in October and November 2007, with a tentative decision to approve the application in December 2007. A final decision to adopt the zoning changes was made on March 20, 2008.

The Marine Industrial zone covers that portion of the Bradwood property formerly occupied by the Bradley-Woodard lumber mill. Much of this land has been raised above the elevation of the adjoining marsh and wetlands by deposition of dredged materials and by fill used to create berms for the railroad and haul road that cross the property. As discussed above, the zone is intended for intensive water-dependent industrial uses, subject to various standards and requirements regarding matters such as buffers, building height, and setback. Therefore, NorthernStar's activities proposed within the Marine Industrial zone are permitted or conditionally permitted uses within this zone.

In the middle of the portion of the Bradwood tract zoned as Marine Industrial is the former mill pond; now partly filled with silt. The county's land use maps show the above-water silted parts of the mill pond to be zoned Marine Industrial and the remaining underwater portion to be zoned Aquatic Development. All the mill pond and Aquatic Development-zoned waters are owned by the state and are not part of the privately owned Bradwood property. In its March 2008 decision, the Clatsop County Board of Commissioners changed the zoning of the 2.51-acre mill pond area from Aquatic Development to Marine Industrial.

Related to the Marine Industrial zone is the DMD Overlay Zone, which applies to the same part of the proposed LNG terminal site that is zoned Marine Industrial. The zone is intended to designate sites for disposal of dredged materials, for which the Bradwood property has already been used. Resulting dredged materials are evident as large sand dunes along the shore of the Columbia River on the eastern part of the site. The provisions of the DMD Overlay Zone are set forth in Clatsop County's LWDUO in section 4.160-4.172. The DMD Overlay Zone is intended to "protect important dredged material disposal sites from incompatible and preemptive uses that may limit their ultimate use for the deposition of dredged material." It thus prohibits many uses that would otherwise be allowed under the Marine Industrial zone as outlined in section 4.168 of the LWDUO and, therefore, the activities proposed by NorthernStar would not be permitted in this zone. The DMD Overlay Zone, however, does contain provisions for withdrawing the DMD designation under certain conditions.

A portion of the land required for the proposed LNG terminal was zoned Aquatic Natural. Generally, the Aquatic Natural designation was intended as a conservation zone for the protection of fish and wildlife habitats, and estuarine and aquatic resources. At the proposed LNG terminal, the Aquatic Natural zone covered a low-lying brushy area of disturbed wetlands bounded on the northwest by Hunt Creek, on the east by the railroad track that runs through Bradwood, and on the southwest by Clifton Road. Two smaller strips of Aquatic Natural-zoned land were also identified between the railroad and tidal marsh and between the berms that support the parallel road and railroad. Typically, intensive industrial activities would not be allowed in Aquatic Natural zoned lands. However, in its March 2008 decision, the Clatsop County Board of Commissioners re-zoned these areas, covering a total of 5.35 acres, to Marine Industrial.

A portion of the land for the proposed berth at the LNG terminal is zoned as Aquatic Development. The Aquatic Development zone applies to an aquatic strip or band of the estuary along the northeastern shore of Bradwood. These Aquatic Development-zoned areas are not part of the privately owned 411-acre Bradwood tract; they are owned by the state. Generally, the zone allows many of the intensive water-dependent industrial uses proposed by NorthernStar, such as "cargo loading and unloading facilities."

The portion of the Columbia River where NorthernStar proposes to create its turning basin/maneuvering area was formerly zoned as Aquatic Conservation Two. This area is owned by the State of Oregon, and NorthernStar would have to acquire permits from the COE, ODSL, and ODEQ, as discussed in sections 1.3 and 4.3.2.3, for the dredging of the turning basin. Generally, as mentioned above, the Aquatic Conservation Two zone is a conservation zone intended to protect estuarine resources. Typically, industrial activities would not be allowed within the Aquatic Conservation Two zone. However, in its March 2008 decision, the Clatsop County Board of Commissioners changed the zoning of the 46.4 acres where NorthernStar would dredge its turning basin to Aquatic Development, and changed the plan designation for this area from Conservation – Other Resources to Development.

The Forest 80 zone applies to lands that would be crossed by the nonjurisdictional power line, and portions of the access roads serving the LNG terminal. However, the access roads are currently cleared and are not actually forested. Generally, as discussed above, this zone is intended to conserve forest lands for growing and harvesting trees. However, roads, transmission lines, and gas pipelines would be allowed within the Forest 80 zone, subject to certain conditions and limitations. Therefore, NorthernStar's activities proposed within this zone appear to be permitted or conditionally permitted uses.

Part of the LNG terminal site contains a quarry, which is subject to a Quarry Mining Overlay. Uses permitted or conditionally permitted in the underlying zone, including "Sensitive Uses," are allowed in the quarry impact area subject to the underlying zone criteria and as otherwise authorized by the energy, social, economic and environmental analysis (section 4.4.20 of the LWDUO). The new use may not interfere with or cause an adverse impact on permitted mineral activity or prevent adjacent mineral activity from meeting applicable standards. The quarry site is under the control of NorthernStar. NorthernStar plans to possibly use material from the quarry during construction of the proposed project and then cease quarry operations during the life of the facility.

The March 20, 2008 final decision by the Clatsop County Board of Commissions to approve the land use applications for the proposed Bradwood Landing Project was based upon NorthernStar accepting a series of conditions, including:

- submittal of copies of state and federal permits required for project development;
- certain stipulations for bridge replacement;
- a specific time window for removing the two concrete batch plants;
- developing and submitting a shoreline monitoring plan prior to dredging;
- maintaining access to Clifton Channel;
- developing and submitting a dredge material disposal plan prior to dredging;
- preventing runoff from the dredge disposal site to adjacent wetlands and intertidal areas;
- revegetation of the dredge disposal area if there is a delay in constructing the facility;
- re-establishment of stream banks and associated vegetation following construction of the electric power lines;
- submitting a site plan demonstrating compliance with county site development standards;

- certain widening and vegetative clearing along Rulryville Road;
- certain signage along Taylorville Road;
- submitting construction drawings for the purposes of flood hazard review;
- not opposing re-zoning of a parcel near the facility as Aquatic Natural;
- only two tanks would be permitted as part of the land-use review process;
- submitting a suitable Mitigation Plan that meets the applicable county performance standards, and is consistent with approvals from other agencies;
- making Clifton and Bradwood Road improvements consistent with county requirements;
- developing a decommissioning plan that includes financial assurance for site restoration;
- implementing safety recommendations outlined in Clatsop County's Public Safety Assessment for the facility;
- securing permits related to constructing and operating the helicopter pad prior to constructing the LNG facility; and
- developing and submitting an erosion control plan consistent with county standards.

In a letter dated November 14, 2007, as part of the application review process noted above, NorthernStar committed to meeting the conditions specified by Clatsop County.

4.7.2.3 Existing Residences and Planned Developments

Existing Residences

Based on review of aerial photographs and site visits, no residences are present within 0.5 mile of the LNG terminal. Two abandoned, unoccupied structures are located within the parcel controlled by NorthernStar. These consist of an open-sided pole barn erected in about 1985 that is partly covered by dredged material and the concrete remains of what was formerly an office building for the Bradley-Woodard lumber mill. The closest residence to the proposed LNG terminal is about 0.6 mile to the northeast across the Columbia River on Puget Island. No hospitals, fire departments, law enforcement offices, churches, or schools are located within 1 mile of the LNG terminal.

There are 21 residences within a 0.6- to 1.0-mile radius around the LNG terminal; all are located on the western tip of Puget Island. NorthernStar identified 45 other residences between 1 and 2 miles away from the terminal, including 3 houses in Clifton. Additionally, about 15 commercial structures were identified between 1 and 2 miles from the proposed LNG terminal.

The closest communities to the proposed LNG terminal are Clifton and Knappa, in Clatsop County, Oregon, and Puget Island and Cathlamet in Wahkiakum County, Washington. Clifton is located about 1 mile west of Bradwood on the south shore of the Columbia River along the Clifton Channel. It was the site of a fish packing factory in the 1870s, but by the 1960s Clifton had lost its post office, and an observer in 2000 counted only about five dwellings there (Helwig, 2000). Knappa is a rural unincorporated community, with a school district and fire department, located more than 3 miles

southwest of Bradwood along Highway 30. Puget Island, situated in the middle of the Columbia River and extending west to east from CRM 38 to CRM 45, has a disbursed rural population of just under 800 people. The town of Cathlamet is the Wahkiakum County seat, first founded by fur traders in the 1840s, and incorporated in 1907. It has a population of about 560 people and is located more than 3 miles northeast of Bradwood, on the other side of the Columbia River. Section 4.8 discusses regional population, local community social services, and infrastructure for the area.

During construction and operation of the LNG terminal there could be impacts on nearby residential and commercial areas from increased traffic on local roads, dust, odors, and noise. There would also be visual impacts for people residing or passing through the viewshed that includes the terminal. In general, as the distance from the terminal increases, the severity of the impacts decreases. We believe that most of the impacts on nearby residential communities related to traffic, dust, and odors would be temporary and short term, and not significant.

The majority of project workers would commute on Highway 30, which could have traffic implications for the communities of Clatskanie to the east and Knappa to the west. In order to allow construction traffic to move to and from the site safely, and lessen the impact on nearby communities, NorthernStar would follow a traffic management plan.

It is possible that construction of the proposed LNG terminal could have temporary adverse impacts on air quality due to fugitive dust emissions. The amount of fugitive dust would depend on the composition and moisture content of soils disturbed during construction activities. Given the regional climate and the distance to nearby residential communities, it is unlikely that fugitive dust from project construction would have an adverse effect. However, NorthernStar would implement BMPs to ensure that dust does not cause a nuisance (see section 4.10.1.2).

Dredging activities can sometimes result in odors, primarily due to hydrogen sulfides released from decaying organic material (e.g., plants) that occur in the dredged sediments. Generally, the greatest potential for odors is shortly after the dredged materials are brought to the surface and when the material is still wet (particularly when temperatures are warm). The sediments to be dredged from the turning basin site do not contain a high percentage of organic material. Additionally, the issue of odors associated with dredged material has not been particularly problematic for other dredging operations on the Columbia River. Therefore, neither dredging nor sediment disposal associated with the Bradwood Landing Project is expected to cause, or contribute to, objectionable odors on nearby residential and commercial areas.

To minimize noise impact on nearby noise-sensitive areas (NSA), NorthernStar would consider incorporating such noise attenuation measures as:

- use of bubble curtains and wooden blocks during pile driving;
- noise barriers or enclosures to block sound transmission from operating equipment;
- use of noise attenuation devices (i.e., exhaust mufflers) on construction equipment to manufacturers' recommended specifications;
- restricting activities with the potential to cause an exceedance of regulatory limits to daylight hours (i.e., dusk to dawn), except dredging;
- working with the dredging contractor to ensure that the project complies with any noise regulations applicable to nighttime construction activities;

- valves with "low-noise" trims;
- acoustical insulation for aboveground piping; and
- selection of equipment types with the least noise emissions.

Additional information on measures NorthernStar would implement to reduce impacts associated with increased traffic, dust, and noise is presented in sections 4.8.2.7, 4.10.1.2, and 4.10.2.2, respectively. Visual impacts are discussed in more detail in section 4.7.2.7.

Planned Developments

We did not identify any future planned residential or commercial developments in close proximity to the proposed LNG terminal. Based on NorthernStar's conversations with Clatsop County, no permits for new developments near the site have been filed (Stoel Rives, 2005). Wahkiakum County's Public Works Department indicated that its current construction projects include countywide guardrails, Altoona Pillar Rock slide repair, Puget Island ferry ramp replacement, West Little Island paving, and Beaver Creek emergency repair. Planned developments identified in the area that may cumulatively or additively impact resources that would be affected by construction and operation of the Bradwood Landing Project are discussed in section 4.12.

4.7.2.4 Coastal Zone Management

In 1972, Congress passed the CZMA to "preserve, protect, develop, and where possible, to restore or enhance, the resources of the nation's coastal zone for this and succeeding generations" and to "encourage and assist the states to exercise effectively their responsibilities in the coastal zone through the development and implementation of management programs to achieve wise use of the land and water resources of the coastal zone" (16 USC 1452, section 303 (1) and (2)).

Section 307 (c)(3)(A) of the CZMA states that "any applicant for a required federal license or permit to conduct an activity, in or outside the coastal zone, affecting any land or water use or natural resource of the coastal zone of that state shall provide a certification that the proposed activity complies with the enforceable policies of the state's approved program and that such activity would be conducted in a manner consistent with the program." In order to participate in the coastal zone management program, a state is required to prepare a program management plan for approval by the OCRM. Once the OCRM has approved a plan and its enforceable program policies, a state program gains "federal consistency" jurisdiction. This means that any federal action (e.g., a project requiring federally issued licenses or permits) that takes place within a state's coastal zone must be found to be consistent with state coastal policies before the federal action can take place.

The Bradwood Landing Project is subject to a federal Coastal Zone Consistency Review because it would: 1) involve activities within the coastal zone of Oregon; and 2) require several federal permits and approvals (see table 1.3-1). Oregon has an approved coastal zone management program administered by the ODLCD, per section 306(d)(5) of the CZMA and ORS196.435. A description of the state's program, the applicable project activities, and information provided by NorthernStar in its FERC section 7(c) application regarding consistency of the project with state policies is provided below.

According to the OCMP, the coastal zone of Oregon encompasses the:

area lying between the Washington and California borders on the north and south, bound on the west by the extent of the state's territorial sea jurisdiction (3 nautical miles offshore), and

extending east to the crest of the Coast Range except at: [a] the Columbia River where the coastal zone extends to the downstream end of Puget Island, [b] the Umpqua River where the coastal zone extends to Scottsburg, and [c] the Rogue River where the coastal zone extends to Agness.

The mission of the OCMP is “to provide the public with sustainable coastal natural resources” (OCMP, 2005). To accomplish this mission, the OCMP has combined various state statutes for managing the state’s coastal lands and waters into a single, coordinated package. The package, administered by the ODLCD, has three basic parts:

1. *The 19 Statewide Planning Goals.* The 19 goals are Oregon’s standards for comprehensive land use planning. The goals set requirements on how land use decisions are to be made by local governments and state agencies. The ODLCD is responsible for adopting and interpreting most of the 19 goals, sets overall rules for planning decisions, and oversees the statewide program.
2. *City and County Comprehensive Land Use Plans.* In Oregon, local governments share the job of land use planning with the state by preparing and adopting plans. Ordinances are then implemented to meet the statewide planning goals and are coordinated with relevant programs of Oregon state agencies. In effect, day-to-day land use decisions can be made by local governments in conformance with their state-approved plans.
3. *State Agencies and Natural Resource Laws.* Since the late 1960s, the Oregon Legislature has adopted numerous statutes in response to threats on coastal and statewide resources from uncontrolled development. These statutes include the Oregon Beach Bill, administered by the Oregon Parks and Recreation Department, and the Removal/Fill Law, administered by the ODSL. All state agencies must also follow certain requirements of the Statewide Planning Goals and must coordinate their land use actions with local government comprehensive land use plans. This helps ensure that all land use decisions by local governments and by state agencies are done more or less under the umbrella of the Statewide Planning Goals.

NorthernStar is coordinating with the COE and ODLCD regarding coastal zone management review as part of the COE section 404 permit application. Federal regulations require the federal consistency determination request to contain at least: 1) a detailed description of the proposed activity; 2) a discussion of anticipated coastal zone effects; and 3) an evaluation of the activity and effects in light of the enforceable policies of the approved OCMP.

NorthernStar submitted a draft consistency certification to the ODLCD on May 31, 2006. A formal certification with a request for a formal federal consistency review was submitted on December 8, 2006. In a January 5, 2007 letter to NorthernStar, the ODLCD stated that the certification did not include the necessary data and information required by 15 CFR 930.58(a) and that the agency’s 6-month review period had not yet begun. Among the information requested and subsequently provided by NorthernStar was: copies of complete applications for federal, state, and local licenses, permits, and approvals; findings that clearly identify data and information from referenced documents together with a clear explanation of why this information leads to a conclusion that a standard is met; additional details on the rail line realignment; the effects and compliance with state and local requirements for the proposed soil disposal area, temporary parking area, power line, concrete plant, aggregate site use, barge operations, road improvements, bridge replacement, mitigation, and in-water dredge material disposal site use; and copies of referenced supporting documents.

NorthernStar submitted a revised consistency certification on October 23, 2007. On November 21, 2007, ODLCD determined that although NorthernStar's application did not include all necessary data, pursuant to 15 CFR 930.60(a)(2) its 6-month review period began with the submission of the revised consistency certification. However, on April 10, 2008, the ODLCD and NorthernStar executed a Stay Agreement that allowed for a 150-day continuation period, when NorthernStar could provide additional information to supplement its application with the ODLCD. According to the Stay Agreement, the ODLCD would make its consistency determination for this project on or before September 21, 2008. On May 9, 2008, ODLCD sent NorthernStar a data request to clarify information about the project.

If the Bradwood Landing Project is authorized by the Commission, NorthernStar would need to document that its project is consistent with the CZMA before the FERC would allow any construction activities to begin. Therefore, **we recommend that:**

- **Prior to construction, of the LNG terminal and pipeline, NorthernStar should file with the Secretary documentation of concurrence from the ODLCD that the project is consistent with the CZMA.**

4.7.2.5 Hazardous Waste Sites

Based on an August 2005 Phase I Environmental Site Assessment, there are no contaminated sites within 0.25 mile of the proposed LNG terminal site (AMEC, 2005). However, the Environmental Site Assessment did identify several RECs on the property. RECs are defined by the presence or likely presence of hazardous substances and petroleum products on a property under conditions that could indicate an existing release, a past release, or a material threat of a release into the ground, groundwater, or surface water. The following RECs were identified at the site:

- REC 1 – two gasoline USTs, of which one was located at a former town store and the other was located at the main mill office. Documentation of their removal or decommissioning was not found;
- REC 2 – an area of the former train/maintenance shop building located at the mill where trains and other equipment were maintained;
- REC 3 – suspect asbestos-containing cement board scattered along the south side of the PWRR tracks;
- REC 4 – solid waste disposal and burn areas located along Bradwood Road, between the northwestern end of town and the Hunt Creek Bridge; and
- REC 5 – the potential presence of PCBs and dioxins in dredged Columbia River sand deposited at the proposed site.

RECs 1 and 2 are buried under dredged material. Because excavations would not be a component of LNG terminal construction, NorthernStar does not anticipate the need to manage potentially contaminated materials associated with RECs 1 and 2.

Before construction, NorthernStar would inspect the area occupied by REC 3. Any suspected asbestos-containing material would be collected and disposed of appropriately and in accordance with applicable state and federal regulations.

Similar to RECs 1 and 2, REC 4 has no surface manifestation and is buried. The realigned railroad and the LNG terminal administrative building would overlap the footprint of REC 4. However, because excavation is not a component of railroad construction and the administrative building would be constructed on fill, it is not anticipated that management of potentially contaminated materials associated with REC 4 would be required.

REC 5 is described as the potential presence of PCBs and dioxins in dredged Columbia River sand deposited at the site. However, in a February 1, 2006 letter from the COE to NorthernStar, the COE stated “USACE dredged material placed at this site is not a potential source of contaminants based on historical information” (COE, 2006).

In summary, management of potentially contaminated materials during LNG terminal construction is not anticipated. However, we have recommended that NorthernStar prepare a *Plan for the Discovery and Management of Contaminated Soils and Groundwater* that would specify the procedures to be followed to identify, characterize, and properly manage potentially contaminated materials in the event they are encountered during construction of the project (see section 4.2.2.1).

4.7.2.6 Recreation, Public Interest, and Special Use Areas

The Bradwood Landing LNG terminal would not affect any national or state parks, Indian reservations, or wild and scenic rivers. The project would be located on private property that does not provide public access to the Columbia River.

There are several recreation and public interest areas located in the vicinity of the proposed LNG terminal. The Clatsop State Forest boundary is about 0.3 mile west of the terminal. Tenasillahe Island, which is part of the JBHNWR, is located about 0.7 mile northwest across Clifton Channel from the terminal. The Bradley State Scenic Viewpoint is located about 1.8 miles southeast of the terminal. The Elochoman Slough Marina at Cathlamet is more than 3 miles northeast of Bradwood. The closest developed public recreational beach is at Skamokawa Vista Park, about 4 miles northwest of the terminal, across the Columbia River in Wahkiakum County, Washington. We do not believe that the project would have any significant adverse effects on these recreational use areas, which are further discussed below.

Designated Recreation and Public Interest Areas

The nearest recreational and public interest areas to the proposed Bradwood Landing LNG terminal include:

- a portion of the LCNHT, which is congruent with the Columbia River and within the area to be affected by terminal construction and operation;
- a portion for the Lower Columbia River Water Trail that is adjacent to the terminal and its LNG carrier berth and within the area that would be dredged for the proposed turning basin/maneuvering area;
- Bradwood Cliffs and old growth forest, which is about 0.2 mile south;
- the Clatsop State Forest, which is about 0.3 mile west;
- the JBHNWR, which is about 0.7 mile north on Tenasillahe Island;
- county land, which is about 1 mile southwest; and
- the Bradley State Scenic Viewpoint, which is about 1.8 miles southeast.

Lewis and Clark National Historic Trail

The LCNHT follows the lower Columbia River adjacent to the proposed LNG terminal at Bradwood, where NorthernStar would dredge its turning basin. Project impacts on the LCNHT are addressed in section 4.9.

Lower Columbia River Water Trail

The Lower Columbia River Water Trail also follows the river past the proposed LNG terminal. The water trail is intended for use by non-motorized water craft mostly during daily excursions. The proposed LNG carrier turning basin/maneuvering area and terminal berth would overlap a portion of the water trail. The dredging for these facilities may temporarily impact users of the water trail during construction. The Zones of Concern along the waterway for LNG marine traffic would also overlap the water trail, and potential project-related impacts associated with LNG carrier transit to and from the terminal are discussed in section 4.7.1.4.

Bradwood Cliffs/Old Growth Forest

Within about 0.25-mile of the proposed LNG terminal are the “Bradwood Cliffs,” which have been identified as a “Scenic and Natural Area” in the Clatsop County Northeast Community Plan. The plan describes the cliffs as follows: “The area consists of 40 acres of old growth Douglas fir forest standing on basalt ledge overlooking the Columbia River. This stand is highly natural and the old growth trees will continue to constitute a viable natural ecosystem if left alone. The steep rocky slopes could not tolerate logging.” Additional details on existing upland forested communities are presented in section 4.4.2.2.

Construction and operation of the LNG terminal would not affect old growth forest or the Bradwood Cliffs, NorthernStar revised the power line route so as to avoid impacts on the old growth forest associated with the Bradwood Cliffs (see section 3.1.7).

Clatsop State Forest

Located about 0.3 mile west of the LNG terminal site in Oregon is the Clatsop State Forest. The *Clatsop State Forest Astoria District Recreation Management Plan* outlines the implementation of recreation management in the state forest through objectives and actions, activity zoning, and the type of facilities the ODF will develop and manage. Dispersed recreational activities occur on forest lands, including hunting, fishing, camping, off-highway vehicle use, horseback riding, mountain biking, hiking, and scenic viewing. The ODF’s Forest Management Plan for Northwest Oregon has Land Management Classification designations that include areas of visual concern. There is a visual designation along the Columbia River on the Clatsop State Forest directly west of the proposed Bradwood Landing LNG terminal.

The only effect the proposed LNG terminal may have on visitors to the Clatsop State Forest would be visual impacts for viewers using the forest. Visual impacts are addressed in section 4.7.2.7.

Julia Butler Hansen National Wildlife Refuge

Located about 0.7 mile north of the LNG terminal site on Tenasillahe Island is the JBHNR. The eastern end of Tenasillahe Island has been used to store materials dredged from the Columbia River during maintenance of the federal navigation channel. The JBHNR was established to protect the endangered Columbian white-tailed deer. It contains several public use facilities. Of these, the closest to

the LNG terminal is the Tenasillahe Island dike, which is open to the public and provides visitors access to the periphery of the island for wildlife viewing opportunities. Tenasillahe Island can only be reached by boat.

During construction and operation of the proposed LNG terminal there could be potential impacts on the JBHNWR, including noise and light. These impacts are discussed elsewhere in this EIS. Visual impacts are addressed in section 4.7.2.7.

County Land

Located about 1.0 mile south-southwest of the LNG terminal site is land owned by Clatsop County. Due to the distance, construction and operation of the Bradwood Landing Project is not expected to have any direct or indirect impacts on this land.

Bradley State Scenic Viewpoint

The Bradley State Scenic Viewpoint, located about 1.8 miles southeast of the proposed LNG terminal, was donated as park land to the Oregon Highway Commission in 1922. It currently serves as a rest stop along Highway 30, accommodates picnicking, and provides a view of the Columbia River and Puget Island. The LNG terminal would not be visible from this spot. However, the proposed power line to the terminal may be visible. Section 4.7.2.7 discusses the visual impacts associated with the LNG terminal.

General Recreation and Special Uses

It is possible that dredging of the turning basin during construction of the proposed LNG terminal may interfere with recreational use of the Columbia River. Because the temporary mooring of the dredge barges would occupy a relatively large portion of the channel throughout dredging operations, this equipment might present an obstruction to navigation; however, dredging would only occur between November and January when river use is lowest. Therefore, impacts on recreational uses of the river during construction would be minor and short term. Operation of the LNG terminal would not significantly affect recreational uses of the river because none of the structures to be constructed as part of the ship berth would be located within the navigation channel. Potential effects on river users resulting from LNG marine traffic in the waterway to the terminal are addressed in section 4.7.1.4.

The primary impact of the proposed LNG terminal on recreational river users in the immediate vicinity would be visual. Visual impacts are discussed in section 4.7.2.7.

4.7.2.7 Visual Resources

The degree of visual impact that may result from a proposed project is typically determined by considering the general character of the existing landscape and the visually prominent features of the proposed facility. The site is bordered on the north and east by the Columbia River, and on the south and west by forest land. Southwest of the proposed site, cliffs between 225 and 235 feet high occur along the southern side of the Columbia River. Hunt Creek enters the site from the south, dropping down from the surrounding hills with a waterfall, and runs along the western side of the site before entering the Columbia River. Views from the site include the confluence of the Clifton Channel and Columbia River, and Tenasillahe and Puget Islands. The terrain in the area of the site is relatively flat along the river and slopes upward west and south of the river. The proposed Bradwood Landing LNG terminal site is not a unique or scenic resource designated by Clatsop County or the State of Oregon. The overall visual

character of the site area is of a previously used industrial site. The dominant visible landforms currently on the site are the piles of dredged materials.

Topography would screen the LNG terminal from view by potential onlookers from the south and west and those traveling along Highway 30. The proposed LNG terminal would be visible from the Columbia River, the western shore of Puget Island, and the JBHNWR (see figure 4.7.2-1). NorthernStar conducted a visual assessment for the proposed project.¹⁶ The results of the visual assessment for the Bradwood Landing Project are summarized below.

Commercial and recreational users of the Columbia River would have an unobstructed view of the LNG terminal from the river, resulting in a high to moderate overall visual impact, depending on the viewer's location and the time of year. Similarly, residents along the western shore of Puget Island and visitors to the portion of the JBHNWR on Tenasillahe Island would also experience unobstructed views of the LNG terminal, resulting in a high to moderate overall visual impact (see figures 4.7.2-2 and 4.7.2-3). Due to distance, intervening islands, and vegetation, views of the LNG terminal site from the portion of the JBHNWR on the Washington side of the Columbia River and Cathlamet would be partially obstructed, resulting in a moderate to low overall visual impact (see figures 4.7.2-4 and 4.7.2-5). Recreational users of Skamokawa Vista Park would have an unobstructed to partially obstructed view of the LNG terminal, depending on their location (see figure 4.7.2-6). However, because the park is located about 4.3 miles north of the proposed site, the resulting potential visual impacts would be low.

The completed LNG terminal would include a variety of structures as described in section 2.1.3. A component of assessing the potential visual contrast of the LNG facilities is to compare the relative scale of the structures to surrounding landscape elements. In that regard, the LNG storage tanks would be the most significant contribution to visual effects simply because of their size. The tanks would be about 254 feet in diameter and about 135 feet high, and would be constructed at a base elevation of about 20 feet above NAVD. As a result, the anticipated elevation at the top of the tanks would be about 155 feet above NAVD. About 500 feet south of the LNG storage tanks are cliffs which rise about 225 to 235 feet in height, and forested hills behind them would be a backdrop reducing visual impacts from viewpoints along the Columbia River. Furthermore, NorthernStar proposes to paint the LNG storage tanks so that they would blend in with the forested hillside in the background. Additionally, a berm would be built around the site approximately 25 feet above the water level and trees would be planted at the shoreline to provide a natural barrier between the river and the LNG terminal.

The exteriors of the LNG terminal structures would be painted to reduce visual impacts. Local planners would be consulted for color tones and hues selection. Colors of building materials suitable for the facility purpose would be chosen to blend into the existing visual environment.

¹⁶ The Visual Assessment for the Bradwood Landing LNG terminal was filed on June 5, 2006 as Appendix 8A of Resource Report 8, and is available to the public through the FERC's Internet website (<http://www.ferc.gov>). Using the "eLibrary" link, select "General Search" from the eLibrary menu and enter the docket number excluding the last three digits in the "Docket Number" field (i.e., CP06-365). Be sure to select an appropriate date range.

The facility would require lighting at night for operational and personal safety and security reasons. For example, lighting would be needed for vessel navigation and for illuminating work areas after sunset. In addition, lights may be needed at the ship berth, construction staging areas, and parking lots. Exterior lighting at the LNG terminal site would be installed as necessary for general plant operations, worker and visitor safety, and security.¹⁷ Lighting at the LNG terminal site is expected to be in accordance with OSHA requirements, with the recommendations of ANSI/IESNA Recommended Practice for Industrial Facilities, other applicable codes, and proper security practices.

NorthernStar filed its Lighting Plan in July 2007, which would minimize the number and/or intensity of facility lighting whenever possible through use of specific lighting intensities, light placement, and height. Down-shielding lights would also be used whenever possible to reduce off-site light scatter and illuminating of facility structures. At the current time there are no nighttime light sources at or in the immediate vicinity of the site. NorthernStar would minimize the impacts of nighttime lighting on surrounding areas through installation of appropriately focused lighting fixtures. Most of the lighting would be located in internal areas of the facility and would, therefore, not have a significant impact on surrounding areas. Overall, lighting impacts would be less than those from other developed areas along the river. Sections 4.5.2.1 and 4.5.2.3 include additional discussion of potential lighting impacts on wildlife.

Because the LNG terminal site is not served by public utilities, NorthernStar would need to supply electrical power to the facility via a 1.5-mile-long power line extension with a 100-foot right-of-way. The power line would interconnect with the existing BPA system and be constructed, owned, operated, and maintained by PacifiCorp. Five new standard pole H-frame towers, measuring 60- to 105-feet tall, would be set about 11 feet into the ground, leaving approximately 50 to 95 feet of power line pole exposed aboveground. Construction and operation of the power line would impact about 16.9 and 5.0 acres, respectively, of forest land, resulting in a permanent impact on visual resources. However, the power line would generally be located adjacent to the Columbia River in a relatively remote, rural area. The power line poles and exposed operational right-of-way would be noticeable primarily from users of the Columbia River and from a few distant vantage points, including the Bradley State Scenic Viewpoint. Figure 4.7.2-7 depicts a visual simulation of the power line from Puget Island. Two of the towers would be visible against the sky. Section 3.1.7 contains a discussion of the power line route alternatives analysis, in which visual impacts were considered.

4.7.3 Pipeline Facilities

4.7.3.1 Land Use

The Bradwood Landing Project would involve construction of one 36.3-mile-long, 30- to 36-inch-diameter pipeline that would connect the LNG terminal with the existing Williams Northwest pipeline north of Kelso, Washington. Additionally, other entities may construct three nonjurisdictional lateral pipelines. These include the 0.2-mile-long, 4-inch-diameter lateral pipeline to the Wauna Mill; the 1.4-mile-long, 24-inch-diameter lateral pipeline to the Northwest Natural pipeline servicing the Mist natural gas storage facility; and the 0.6-mile-long, 12-inch-diameter lateral pipeline to the PGE Beaver Power Plant. Table 4.7.3-1 summarizes the land uses crossed by the proposed pipeline and lateral routes.

¹⁷ The Office of Pipeline Safety (OPS) within the DOT has statutory authority to regulate the safety and security of LNG plants under the Natural Gas Pipeline Safety Act of 1968 (P.L. 90-481). The OPS security regulations for LNG facilities are found in Title 49 CFR 193, Liquefied Natural Gas Facilities: Federal Safety Standards (Subpart J-Security). These regulations govern security procedures, protective enclosures, communications, monitoring, lighting, power sources, and warning signs. Title 49 CFR 193.2911 deals specifically with security lighting requirements.

^g	Water includes streams and canals.																
Con.	Construction																
Oper.	Operation																

Of the 36.3 miles of the NorthernStar pipeline route, about 8.0 miles (22 percent) would be constructed adjacent to the existing KB pipeline. The remaining 78 percent of the pipeline route would be constructed on newly created right-of-way.

The predominant land use that would be crossed is forest, comprising about 50 percent of the pipeline route. Agricultural and rangeland are the next two most predominant land uses affected.

About 8.2 miles of the pipeline would cross forest land, 8.3 miles would cross wetlands, 6.7 miles would cross agricultural land, 4.8 miles would cross rangeland, 2.9 miles would cross commercial land, 0.2 mile would cross residential land, 3.0 miles would cross open land, and 2.2 miles would cross open water. Wetland and upland communities crossed by the proposed route are described in detail in section 4.4.1.3 and 4.4.2.3, respectively.

Land use impacts associated with the pipelines would include the disturbance of existing land uses within the construction right-of-way during construction and retention of a new permanent right-of-way for operation of the pipeline. NorthernStar proposes to use a 100-foot-wide construction right-of-way for the majority of the pipeline route. NorthernStar has also indicated that an additional 20 feet of construction right-of-way width may be needed for stockpiling topsoil wherever topsoil must be segregated from subsoil (e.g., in agricultural and residential lands). The 20 feet of additional width is based on the segregation of up to a 12-inch-thick layer of topsoil excavated only from directly over the pipe ditch and under the spoil pile (ditch plus spoil side).

In addition, in wetlands where the crossing length is 100 feet or less, NorthernStar would reduce the construction right-of-way to a width of 85 feet. The 85-foot limitation on the construction right-of-way width would not apply to wetlands in actively cultivated or rotated cropland. Appendix F provides a list by milepost of the locations where NorthernStar would use an 85-, 100-, or 120-foot-wide construction right-of-way.

Where the Bradwood Landing pipeline would be adjacent to the existing KB pipeline, the proposed temporary construction right-of-way would overlap onto the existing pipeline's permanent right-of-way. The overlap would be up to 10 feet on the spoil side of the pipe ditch, but no closer than 15 feet from the existing pipeline to keep construction equipment off the operating pipeline to prevent damage to the existing line.

Following construction, a 50-foot-wide permanent right-of-way would be maintained for operation and maintenance of the pipeline. The typical right-of-way cross sections that NorthernStar would use for the pipeline route are provided in Appendix D.

In addition to the construction right-of-way, NorthernStar would require temporary extra workspace outside the standard construction right-of-way at locations where additional excavation, soil placement requirements, or equipment management and staging would make it impracticable to carry out all construction operations within a 100-foot-wide corridor. These would include road and railroad crossings; wetland and waterbody crossings, areas with steep side slopes or severe terrain, areas requiring topsoil segregation, truck turnarounds, hydrostatic test water withdrawal pump locations, hydrostatic test water discharge locations, pipeline and utility crossovers, tie-ins to existing pipelines and laterals, HDD entry and exit points, staging and fabrication areas for HDD pull sections, and foreign pipeline crossings. Extra workspace may also be required where special construction techniques would be used. The size and configuration of each extra workspace is unique and dependent upon the existing conditions (e.g., available or accessible space, the presence of buildings and other structures, crossing angle, crossing depth, length of crossing, terrain, the presence of trees or sensitive habitat) at each work location. Table 4.7.3-2 lists by milepost the locations of and land uses affected by additional temporary workspaces required for pipeline construction. NorthernStar would access the construction right-of-way via existing public and private roads that intersect the right-of-way. Modifications or improvements to support the expected loads would not be required. Table 4.7.3-3 lists by milepost the roads identified by NorthernStar that would be used to access construction.

To support construction of the pipeline, NorthernStar proposes to use two pipe storage and contractor yards, one in Oregon (Yard A) and one in Washington (Yard B). Both pipe storage and contractor yards would be located on previously disturbed land. Yard A would be located within a fill site for dredged material located on the Wauna Mill property (at about MP 4.4) and would affect approximately 9.1 acres (see figure 2.3.3-1). Yard B would be located in a commercially zoned area off of Washington Way in Longview, Washington and would affect approximately 9.3 acres (see figure 2.3.3-2).

NorthernStar proposes to construct the following: 1) one pig launcher within the LNG terminal at MP 0.0, one launcher/receiver at MP 18.8, and one pig receiver at the pipeline terminus at MP 36.3; 2) a meter station at each of the following five locations: the LNG terminal (MP 0.0), the delivery point to the Wauna Mill (MP 3.7), the interconnection with the Northwest Natural intrastate pipeline to the Mist storage facility (MP 11.4), the delivery point to the PGE Beaver Power Plant at Port Westward (MP 18.9), and the terminus of the pipeline at the interconnection with Williams Northwest (MP 36.3); and 3) four MLVs at MPs 3.7, 18.8, 26.3, and 31.7. Table 4.7.3-4 summarizes by milepost the land use impacts at the proposed aboveground facilities.

Total Land Use for Aboveground Facilities		4.8	1.2	
^a Land use impacts associated with the launcher and receiver are included with the LNG terminal acreage totals included table 4.7.2-1 and, therefore, are not included as part of the total land use affected by the aboveground facilities associated with the pipeline.				

Construction of the pipeline facilities would disturb a total of about 553.0 acres of land, including the pipeline construction rights-of-way, temporary extra workspace, two pipe storage and contractor yards, and aboveground facilities. Of this total, 475.8 acres would be disturbed by the pipeline construction rights-of-way, 54.0 acres would be disturbed by temporary extra workspace, 18.4 acres would be disturbed by the pipe storage and contractor yards, and 4.8 acres would be disturbed by aboveground facilities. Table 4.7.3-5 summarizes the acres of each land use that would be affected by construction and operation of the proposed pipeline facilities.

Forest land would be the primary land use affected by construction of the pipeline facilities, totaling about 308.8 acres (56 percent). The remaining land uses that would be disturbed consist of 90.2 acres (16 percent) of agricultural land, 58.8 acres (11 percent) of rangeland, 51.6 acres (9 percent) of commercial land, 26.7 acres (5 percent) of open land, 15.1 acres (3 percent) of water, and 1.8 acres (less than 1 percent) of residential land.

Of the 553.0 acres of land affected by construction of the pipeline facilities, about 232.8 acres would be retained as permanent right-of-way for the pipelines and 1.2 acres would be retained for aboveground facilities. The land retained for the meter stations and MLVs would be fenced and off limits to any future development. The land that is retained as permanent right-of-way for the pipeline would be allowed to revert to former use with certain restrictions. Activities such as the construction of aboveground structures, including houses, house additions, garages, patios, pools, or any other object not easily removable, or the planting and cultivating of trees or orchards, would be prohibited within the permanent right-of-way. The permanent right-of-way would result in long-term impacts on about 143.9 acres of forest land and about 1.7 acres of orchards, groves, vineyards, or nurseries included with agricultural land. The remaining areas that are used for construction (e.g., rangeland, additional temporary workspace) would be allowed to revert to prior uses following construction with no restrictions.

TABLE 4.7.3-5																
Acres of Land Affected by Construction and Operation of the Pipeline Facilities for the Bradwood Landing Project

Oper.	Operation															

One specialty crop would be affected by construction of the proposed pipeline, a Christmas tree farm. The Christmas tree farm is located in Cowlitz County, Washington and would be crossed between MPs 31.7 and 32.0. NorthernStar has stated that it would initiate discussions with the landowner(s) before construction to coordinate activities to occur at a time that would minimize impacts on the productivity of the tree farm, such as constructing after harvest periods. After construction activities are completed, NorthernStar would repair and/or restore all contours and grade to as near original conditions as possible.

Nearly 93 percent of the pipeline facilities would be located on privately owned lands with the exception of those portions of the pipeline within public road rights-of-way and state and local lands discussed in section 4.7.3.6. NorthernStar would need to acquire new easements or property to construct and operate the proposed facilities. The easement would convey both temporary (for construction) and permanent rights-of-way to NorthernStar and would give NorthernStar the right to construct, operate, and maintain the pipeline facilities. Typically, NorthernStar would negotiate a one-time payment for each easement. Some land management agencies (e.g., the WDNR) may request alternate easement payment schedules. An easement agreement between a company and a landowner typically specifies compensation for losses resulting from construction, including losses of non-renewable and other resources, damages to property during construction, and restrictions on existing uses that would not be permitted on the permanent right-of-way after construction.

If an easement cannot be negotiated with a landowner and the project has been certificated by the FERC, the company may use the right of eminent domain granted to it under section 7(h) of the NGA and the procedures set forth under the Federal Rules of Civil Procedure (Rule 71A) to obtain the right-of-way and extra workspace areas. The company would still be required to compensate the landowner for the right-of-way and damages incurred during construction. However, the level of compensation would be determined by a court according to state or federal law.

4.7.3.2 Consistency with Existing Land Use Plans, Policies, Designations, and Guidelines

Clatsop County, Oregon

The first 6.2 miles of the proposed Bradwood Landing sendout pipeline would be in Clatsop County, Oregon. As discussed in section 4.7.2.2, land use in Oregon must be consistent with the Statewide Land Use Planning Goals, which have been established in Clatsop County by its Comprehensive Plan. The proposed pipeline facilities in Clatsop County, Oregon would cross lands zoned as Marine Industrial, Forest 80, Heavy Industrial, Lake and Wetlands, Aquatic Development, Open Space, Parks, and Recreation, and Exclusive Farm Use. According to the Clatsop County's LWDUO, the pipeline facilities appear to be consistent with the base zoning as listed in table 4.7.3-6.

TABLE 4.7.3-6	
Clatsop County Comprehensive Plan Land Use Zones Related to the Bradwood Landing Pipeline	
Comprehensive Plan Zone	Use Description (LWDUO Section Reference)
Marine Industrial	Water-dependent industrial and port uses, including fuel dispensing facilities (section 3.624(10)). Utilities, maximum utilization of existing easements and rights-of-way shall be made (section 3.624(13)). ^a Public utility structures (section 3.626(1)). ^a
Forest 80	Physical alterations to the land auxiliary to forest practices including, but not limited to, those made for purposes of exploration, mining, commercial gravel extraction and processing, landfills, dams, reservoirs, road construction, and recreational facilities (section 3.553(2)). Utility facilities for the purpose of generating power subject to the standards in section 3.509. A power generation facility shall not preclude more than 10 acres from use as a commercial forest operation unless an exception is taken (section 3.555(11)). ^a New gas distribution lines with rights-of-way 50 feet or less in width subject to standards in section 3.509 (section 3.554(5)).
Heavy Industrial	Utilities with maximum utilization of existing easements and rights-of-way (section 3.404(5)). ^a Distribution services (section 3.405(2)).
Lake and Wetlands	Submerged pipeline (section 3.613 (4)).
Aquatic Development	Water-dependent use and pipelines (section 3.746(1)).
Open Space, Parks, and Recreation	Amended to include cable, sewerline, waterline, or other pipeline (section 3.584).
Exclusive Farm Zone	Utility facilities necessary for public service (section 3.564(4)).
^a Utilities are defined in LWDUO section 1.030 as local sewer, water, gas, telephone, and power distribution lines necessary for local utility service. Included in this definition are uses needed to operate transmission and distribution lines such as pumping stations, repeater stations, and water storage tanks. Clatsop County ruled that the proposed Bradwood Landing pipeline does not qualify as a utility as defined in the LWDUO because it would not provide local service.	

In March 2006, NorthernStar met with the Clatsop County Planning Director to obtain land use ordinance information and to discuss local land use regulations. NorthernStar reviewed the Geologic Hazards Overlay District (GHO), Flood Hazard Overlay District (FHO), and Shoreland Overlay District (SO) ordinances determined by the county as relevant to the proposed project. Clatsop County's GHO does not identify permitted uses but rather requires the applicant to obtain a geologic hazard permit and identifies requisite geotechnical report and construction requirements. Similarly, the FHO identifies standards applicable to construction in flood plains.

The SO is described in section 4.084 of the LWDUO as "areas described on official Clatsop County Zoning Maps. It does not include shoreland areas of the Columbia River Estuary designated Marine Industrial Shoreland, Conservation Shoreland, or Natural Shoreland." The SO also classifies

certain coastal shorelands as Category 1 or Category 2. Category 1 lands are described in the Estuarine and Coastal Shoreland Element of the Clatsop County Comprehensive Plan as:

- 8.1.1 significant, non-estuarine marshes;
- 8.1.2 riparian resources;
- 8.1.3 significant fish and wildlife habitat;
- 8.1.4 exceptional aesthetic resource; and
- 8.1.5 historical and archaeological sites.

Category 2 lands are shorelands that are not Category 1 lands and are not zoned Marine Industrial Conservation Shorelands or Natural Shorelands (section 4.086 of the LWDUO).

NorthernStar, in coordination with the county, reviewed the CREST's resource maps showing the SO boundary. One map depicted the project as within the SO boundary, while another did not. While it was unclear through NorthernStar's conversations with the county whether the project would be located within the SO zone, the Clatsop County segment of the pipeline does not appear to be subject to the SO restrictions because it would be located within areas zoned Marine Industrial, which are expressly exempted from the SO regulations.

Based on NorthernStar's review, the remainder of the pipeline in Clatsop County would not affect land described in the Estuarine and Coastal Shoreland Element of the Comprehensive Plan as Category 1 (i.e., significant non-estuarine marshes, riparian resources, significant fish and wildlife habitat, exceptional aesthetic resource, or historical and archaeological sites). However, the proposed route would affect wetlands and habitat areas. If any of the Clatsop County lands affected by the project are determined to be Category 1 lands, the pipeline use would not be allowed on those lands under the zoning ordinances (section 4.088 of the LWDUO). If no Category 1 lands are to be affected, the area would default to Category 2 lands but only if regulated by the SO overlay, which, as described above, does not apply because the area is zoned Marine Industrial.

In addition to the ordinances described above, part of the Bradwood Landing LNG terminal site in which a portion of the pipeline would be located is designated as a DMD Overlay Zone (see section 4.7.2.2). The DMD Overlay Zone ordinance does not allow uses that would preclude use of the site for disposal of dredged material. The installation of the pipeline would not preclude the use of the LNG terminal site for dredged material placement. In addition, installation and operation of the pipeline would not interfere with ongoing quarry operations or permitted quarry activity.

As previously mentioned in section 4.7.2.2, NorthernStar filed a land use application with Clatsop County in December 2006. On February 9, 2007, NorthernStar filed an application with Clatsop County to amend the Clatsop County Land Development and Water Use Ordinance to add "cable, sewerline, waterline, or other pipeline" as permitted uses in Open Space, Parks, and Recreation zones. The proposed amendments were accepted by the Clatsop County Board of Commissions in their March 20, 2008 decision regarding the Bradwood Landing Project, subject to some specific conditions, as discussed below.

Clatsop County found that the pipeline would be consistent with applicable provisions of its Flood Hazard Overlay Zone. The way in which the pipeline would be installed underground should not displace floodwater. However, one of the conditions of the Clatsop County's approval of NorthernStar's land use application was that the pipeline should be properly backfilled, and the right-of-way graded and restored, so as not to impede drainage or increase the risk of flooding.

Clatsop County indicated that no specialized standards exist in the LWDOU intended to address natural gas pipelines. However, it believes that there are standards for riparian protection outlined in section 4.237 of the County's Standards Document that would apply to this project, because the pipeline would be a development "affecting vegetation adjacent to and bordering Columbia River estuarine aquatic areas." Therefore, as part its conditional approval of NorthernStar's land use application, Clatsop County indicated that a riparian vegetation restoration plan should be prepared. Potential impacts on wetlands would be mitigated by HDDs at some locations along the pipeline route in Clatsop County, and implementation of the measures outlined in NorthernStar's *Waterbody and Wetland Construction and Mitigation Procedures Plan*.

Clatsop County found the pipeline crossing of Marine Industrial-zoned land, where it begins in the tract containing the LNG import terminal, to be allowed as a water-dependent activity. The pipeline crossing of about 2.6 miles of Forest 80-zoned land would be allowed by Clatsop County as a "new distribution line," conditioned on the restoration of the temporary construction right-of-way outside of the 50-foot-wide permanent operational pipeline easement. Clatsop County found the pipeline crossing of about 2.6 miles of Heavy Industrial-zoned land in the vicinity of the Wauna pulp mill to be a conditionally allowed use, provided that state and federal wildlife agencies are consulted regarding potential impacts and mitigation for the Columbian white-tailed deer. The pipeline would cross a short segment of land zoned as Lakes and Wetlands at Driscoll Slough. Because NorthernStar would use an HDD to avoid impacts on Driscoll Slough, Clatsop County considers this to be a permitted use within this zone as a submerged pipeline. The pipeline would also cross Westport Slough with an HDD, in an area zoned as Aquatic Development, and Clatsop County found this to be an allowed use. Near River Ranch, in the vicinity of MP 5.3, the pipeline would cross about 0.7 mile of land zoned as Open Space, Parks, and Recreation. As a result of its review of NorthernStar's request for amendment, Clatsop County revised its plan for Open Space, Parks and Recreation-zoned lands to allow for pipeline crossings. Lastly, Clatsop County found that the pipeline crossing of about 0.2 mile of land zoned for Exclusive Farm Use, designed as Rural Agricultural Land in the Comprehensive Plan, at about MP 6.0, would be an allowed use.

Columbia County, Oregon

The proposed Bradwood Landing sendout pipeline would cross lands within Columbia County, Oregon between MPs 6.2 and 18.9. In March 2006, NorthernStar met with Columbia County's Chief Planner to obtain land use ordinance information and to discuss local land use regulations. Similar to Clatsop County, the Statewide Land Use Planning Goals are implemented in Columbia County through its state-acknowledged Comprehensive Plan. The Comprehensive Plan is implemented through the Columbia County Zoning Ordinance and related land use implementing ordinances.

The proposed pipeline in Columbia County, Oregon would cross lands zoned as Primary Agriculture (PA-38) between MPs 6.2 to 12.5 and MPs 13.2 to 17.4; lands zoned as Resource Industrial - Planned Development (RIPD) between MPs 17.4 to 19.0; and lands zoned as Rural Residential - 5 Acre Minimum (RR-5) between MPs 12.5 to 13.2. The proposed pipeline crossing of PA-38 zoned lands is allowed as a conditional use because it is a facility necessary for public utility service (Zoning Ordinance Section 303.8). Conditional uses may be approved in the PA-38 zone when an applicant satisfies all the requirements for obtaining a conditional use permit.

The proposed pipeline crossing RIPD-zoned lands would be allowed as a conditional use because it constitutes the "distribution of services" under Columbia County Zoning Ordinance Section 683.1. A permit with conditions is typically approved by the County Planning Commission when an applicant demonstrates that its proposal would conform to the goals and policies of the Comprehensive Plan.

The proposed pipeline is not allowed as an outright or conditional use in the RR-5 zone. The county would usually have to rezone this segment of the pipeline route or amend its zoning ordinance to allow this use. However, in a letter to the FERC dated July 12, 2006, the Planning Director for Columbia County indicated that land use approvals are not required for the Bradwood Landing Project in Columbia County, because the county believes its local permitting process is preempted by the FERC's authority to site pipelines under the NGA. The county indicated that it would raise with the FERC any significant issues it may identify in the future regarding inconsistencies the project may have with its Comprehensive Plan and local land use implementing ordinances.

Cowlitz County, Washington

The proposed Bradwood Landing pipeline would cross lands within Cowlitz County, Washington between MPs 19.4 and 36.3. In March 2006, NorthernStar met with Cowlitz County's land use and environmental planning staff to discuss its proposed pipeline facilities, and applicable county plans, policies, designations, regulations, and guidelines.

The proposed pipeline segment in Cowlitz County would be located entirely within an "unclassified" (also referred to as "unzoned") area. The CCC section 18.10.270, states that the unclassified areas "are generally those expansive areas of Cowlitz County which have not had extensive urban development and probably would not have any degree of such development in the foreseeable future." CCC section 18.10.275 also states that "all uses which have not been declared a nuisance by statute, resolution, ordinance, or court of competent jurisdiction are permitted." Therefore, construction and operation of the proposed pipeline facilities appear to be a permitted use not subject to conditional use approval criteria. Unzoned or unclassified areas remain subject to county and state environmental regulations, including the Shoreline Management Act (RCW 90.58) and the county's Critical Areas Ordinance (CCC Chapter 19.15), which are discussed below.

Cowlitz County would consider issuing a general permit for the pipeline under its Gas and Oil Pipelines Ordinance and review of the project for compliance with the Cowlitz County Comprehensive Plan. The Cowlitz County Comprehensive Plan includes all of the county's formally adopted land use planning goals and policies. The plan generally references "utilities," including natural gas pipelines, within the economic development element and the land use element. Generally speaking, the Cowlitz County Comprehensive Plan policies encourage minimization of negative environmental impacts, including impacts on shorelines and adjacent land uses. The plan also encourages utilization of corridor areas for agricultural and small tree production; imposes guidelines to "establish common or jointly used corridors" and placement of utility lines "closer together;" encourages utility companies to "make arrangements, where practical, to use existing rights of way;" and requires control of noxious weeds. Based on NorthernStar's discussions with county staff, compliance with the Shoreline Management Act, would be considered concurrently with the project's SEPA review. County staff also indicated that through the general permit, the county typically seeks assurance that the pipeline is a safe facility. Permits under Cowlitz County's Floodplain Management and Forest Lands Conversion Ordinances could also be considered.

Cowlitz County's SMMP was adopted to implement state planning and regulatory requirements under the Shoreline Management Act. A shoreline substantial development permit and potentially a shoreline conditional use permit for portions of the pipeline proposed within 200 feet of the ordinary high water line of "shorelines of the state" may be reviewed under the SMMP. The Columbia River and six other streams along the proposed corridor are considered shorelines of the state. Further, NorthernStar's facilities would be located in the Conservancy, Urban, and Rural Districts of the shoreline. In these districts, utilities including gas pipelines are a permitted use, subject to requirements to minimize impacts on vegetation and the environment, and subject further to sufficient restoration measures (see section

4.3.2.4). In the event that all surface impacts on jurisdictional shorelines are avoided through HDD or conventional bore construction methods (with bore hole pads set back from the ordinary high water mark and associated wetlands by at least 200 feet), it appears that the proposed pipeline segment through Cowlitz County would be consistent with the substantial development and conditional use provisions of the SMMP.

Cowlitz County's Critical Areas Ordinance requires critical areas permits for disturbance of wetlands, critical aquifer recharge areas, fish and wildlife habitat conservation areas, frequently flooded areas, and geologically hazardous areas. Critical areas permits are administrative permits and generally control the development standards to minimize impacts on critical areas. NorthernStar would design its project to be consistent with the local Critical Areas Ordinance. The county staff appeared most concerned about the pipeline's potential impacts on streams and the crossing of geologically sensitive areas. Detailed information on geological hazards and streams crossed by the pipeline is presented in sections 4.1.4.3 and 4.3.2.4 of this EIS.

Cowlitz County is the SEPA lead agency and is responsible for coordinating the SEPA and the NEPA reviews. This EIS may be used to satisfy the SEPA if the requirements of WAC 197-11-610 and 197-11-630 are met. After the final EIS for the Bradwood Landing Project is issued by the FERC, Cowlitz County would adopt it if an independent review of the document confirms that it meets the county's environmental standards. As indicated in section 1.4, we met with Cowlitz County staff in December 2006 to discuss this EIS and compliance responsibilities under the SEPA.

4.7.3.3 Existing Residences and Planned Developments

Existing Residences

Table 4.7.3-7 lists by MP residences that NorthernStar identified to be within 50 feet of construction work areas for its proposed pipeline. No residences are located within 50 feet of the aboveground facilities associated with the proposed Bradwood Landing sendout pipeline. NorthernStar did not identify any residences immediately adjacent to the proposed pipeline in Clatsop County, Oregon, between MPs 0.0 and 6.2.

TABLE 4.7.3-7			
Structures Located Within 50 Feet of the Pipeline Construction Work Areas ^{a, b}			
County, State/ MP	Type of Structure	Distance from Pipeline Centerline (feet)	Distance from Construction Work Space (feet)
Columbia County, Oregon			
13.1	Residence	50	30
13.4	Barn and workshops	63	32
15.0	Residence	9	Within
17.7	Residence	50	25
Cowlitz County, Washington			
34.1	Barn	40	5
34.7	Shed	93	38
^a Structures, buildings, or residences that would be avoided by the HDD method are not included in this table as impacts on these structures would be avoided.			
^b Based on review of aerial imagery.			

Within Columbia County, Oregon, between MPs 6.2 and 18.9, NorthernStar identified three residences and one barn within 50 feet of its proposed pipeline construction right-of-way. NorthernStar

would avoid impacts on two residences located at about MP 17.5 by moving the pipeline to the opposite side of Hermo Road.

NorthernStar did not identify any residences within 50 feet of the proposed pipeline in Cowlitz County, Washington, between MPs 19.4 and 36.3. However, the pipeline construction right-of-way would be within 50 feet of a barn at about MP 34.1, and close to a maintenance shed for a nearby rock quarry at about MP 34.6. In addition, impacts on two residences at about MP 21.1 would be avoided by the use of an HDD under Germany Creek, while impacts on a residence at about MP 28.1 would be avoided by the use of an HDD under Coal Creek.

In residential areas, impacts associated with installation of an underground natural gas pipeline include disturbance during construction and encumbrance for future uses (e.g., the limitation on future permanent structures within the permanent right-of-way). In general, as the distance from the construction work area increases, the impacts on residences decrease.

Temporary construction impacts on residential areas could include inconvenience caused by construction related traffic; blocking of roads and driveways; noise and dust generated by construction equipment; ground disturbance of lawns; removal of trees, landscaped shrubs, or other vegetative screening between residences and/or adjacent rights-of-way; potential damage to existing septic systems or wells; and removal of aboveground structures, such as sheds or trailers, from within the right-of-way.

Potential impacts on wells and proposed mitigation measures are discussed in Section 4.3.1.4. On December 21, 2007, NorthernStar filed with the FERC a *Residential Construction Conceptual Mitigation Plan*.¹⁸ This conceptual plan outlined the following general measures that NorthernStar would implement to minimize construction related impacts on residences and other structures located within 50 feet of the proposed pipeline construction right-of-way:

- install fencing on the edge of the construction right-of-way for 100 feet on each side of the residence;
- implement dust control plans;
- cleanup construction work areas daily;
- preserve landscaping and mature trees to the extent possible;
- restore lawns and landscaping immediately after backfilling the trench;
- weld, inspect, and coat pipe before excavation of the trench;
- excavate the trench only at the time when the pipe is ready to be lowered in;
- backfill immediately after the pipe is lowered into the trench;
- construct during daylight hours, according to the landowner's needs;
- discuss spoil management with the landowner;
- discuss removal of trees with the landowner;
- reach agreement with the landowner during easement negotiations about plantings in pasture; and
- discuss temporary relocation of the residents during construction.

¹⁸ NorthernStar's Residential Construction Conceptual Mitigation Plan was filed on December 21, 2007, in response to recommend Environmental Condition 31 in our draft EIS. This document can be viewed by the public through the eLibrary link on the FERC internet webpage at www.ferc.gov. Put in Docket No. CP06-365, the date of the filing, and look up accession number 20071226-0098.

Our review of this conceptual plan found that it did not address the full range of potential impacts on residences close to the construction right-of-way. For example, some commentors on our draft EIS questioned how potential impacts on septic systems from pipeline construction activities would be mitigated.

NorthernStar recognized that it did not yet have access to some properties along the pipeline route, and so it could not develop detailed site-specific residential construction mitigation plans for all houses within 50 feet of the construction right-of-way. NorthernStar committed to filing a final formal site-specific residential construction mitigation plan, after the FERC issues an Order authorizing the project, but before construction of the pipeline would begin. Therefore, **we recommend that:**

- **Before pipeline construction begins, NorthernStar should file with the Secretary, for the review and written approval of the Director of OEP, a plan outlining measures that should be implemented to mitigate pipeline construction impacts on domestic water supply systems and septic systems. For all residences located within 50 feet of the pipeline construction work area, during construction of the pipeline, NorthernStar should:**
 - a. **not remove mature trees and landscaping within the edge of the construction work area, unless necessary for safe operation of construction equipment;**
 - b. **immediately after backfilling the trench, restore all lawn areas and landscaping within the construction work area consistent with the requirements of the FERC staff's Plan;**
 - c. **fence the edge of the construction work area adjacent to the residence for a distance of 100 feet on either side of the residence to ensure that construction equipment and materials, including the spoil pile, remain within the construction work area;**
 - d. **try to maintain a minimum distance of 25 feet between the residence and the edge of the construction work area; and**
 - e. **for any residence closer than 25 feet to the construction work area, file a site-specific plan with the Secretary for the review and written approval of the Director of OEP before pipeline construction. The plan should include:**
 - (1) **a description of construction techniques to be used (such as reduced pipeline separation, centerline adjustment, use of stove-pipe or drag-section techniques, working over existing pipelines, pipeline crossover, bore, etc.), and include a dimensioned site plan that shows:**
 - i. **the location of the residence in relation to the new pipeline and, where appropriate, the existing pipelines;**
 - ii. **the edge of the construction work area;**
 - iii. **the edge of the new permanent right-of-way; and**
 - iv. **other nearby residences, structures, roads, or waterbodies.**

- (2) a description of how NorthernStar would ensure the trench is not excavated until the pipe is ready for installation and the trench is backfilled immediately after pipe installation; and
- (3) evidence of landowner concurrence if the construction work area and fencing would be located within 10 feet of a residence.

To minimize additional impacts on traffic, NorthernStar would minimize trips to and from Bradwood, and would develop a traffic management plan (see section 4.8.2.7).

Planned Developments

We did not identify any future planned residential or commercial developments in close proximity to the proposed pipeline route in Clatsop County Oregon. In comments on our draft EIS, Cowlitz County, Washington, indicated that William and Marjorie Castle submitted a building permit application to the county for a proposed single family dwelling located adjacent to the Bradwood Landing pipeline route. Therefore, **we recommend that:**

- **Prior to construction of the pipeline, NorthernStar should study Cowlitz County records to determine all plans for future residential and commercial developments along the proposed pipeline route in Washington, and file the results of that study with the Secretary, for the review and written approval of the Director of OEP. The study should specifically include the Castle family house plans, and provide details about how NorthernStar would avoid or mitigate impacts on that future residence, including the distance (in feet) from the proposed house to the pipeline construction right-of-way.**

Columbia County has identified several development projects at the Port Westward Industrial Area, including a recently completed 400 MW gas-fired electric generation plant operated by PGE, an ethanol plant currently being installed by Cascade Grain Products, LLC, and a 536 MW power plant to be built in the near future by Summit Westward Energy, LLC. The county has invested about \$16.5 million to make road and access improvements at the Port Westward Industrial Area, to be completed by the end of 2009, and it is concerned about potential impacts of the Bradwood Landing Project on those improvements.

Maps received from the Port of St. Helens and PGE also show that the proposed Bradwood Landing pipeline would cross a potential future outfall connection and a proposed Port of St. Helens industrial discharge line at approximate MPs 18.8 and 18.9, respectively, and be within 100 feet of an unidentified potential future facility between MPs 18.5 and 18.7. Further, the Oregon Economic and Community Development Department and Columbia County Regional Coordinator have identified road and water improvement projects in Port Westward and the proposed project vicinity that are either currently ongoing or proposed.

During planning of the proposed pipeline, landowners expressed concerns about impacts of the proposed route on agricultural land in the Port Westward area. Port of St. Helens staff expressed additional concerns (e.g., conflicts with existing infrastructure, existing industrial development, and planned development) regarding the original proposed pipeline route. In response, NorthernStar developed an alternative route variation between approximate MPs 13.5 and 18.2 that follows property boundaries and road alignments and would minimize impacts on active agricultural areas without significant additional construction impacts on natural resources (see section 3.1.8.2). This new pipeline

alignment, which increased the length of the pipeline by 1.6 miles, also would minimize potential conflicts with future development projects.

The currently proposed route for the Bradwood Landing pipeline, as illustrated in the maps attached in Appendix B to the draft EIS, shows it on the north side of Collins Road between about MPs 16 and 17, then being adjacent to the east side of Hermo Road from about MPs 17 to 18. In comments filed December 19, 2007 on our draft EIS, Columbia County indicated that it intends to expand Hermo Road on its east side, so there would be a potential conflict with the installation of the Bradwood Landing pipeline. Therefore, **we recommend that:**

- **Prior to pipeline construction, NorthernStar should document that it has consulted with the Port of St. Helens, the Columbia County Development Agency, and other appropriate agencies and representatives of Columbia County, to determine if its pipeline may have impacts on county improvements in the vicinity of the Port Westward Industrial Area, and file with the Secretary a plan to avoid or mitigate those impacts, for the review and written approval of the Director of OEP.**

4.7.3.4 Coastal Zone Management

Section 4.7.2.4 addresses coastal zone management review for the entire Bradwood Landing Project, including the pipeline facilities.

4.7.3.5 Hazardous Waste Sites

In February and April 2006, NorthernStar conducted a search of environmental records to identify locations of known or potential contamination within the project vicinity. The records reviewed included over 50 federal and state databases including the EPA's National Priorities List (NPL), CERCLIS, and Resource Conservation and Recovery Information System (RCRIS); the ODEQ's Environmental Cleanup Site Information System (ECSI), Oregon Solid Waste Facilities list, Underground Storage Tank database, and Spills Data; and the WDE's Confirmed & Suspected Contaminated Sites List (CSCSL), Hazardous Sites list, Underground Storage Tank database, and Aboveground Storage Tank list. Based on these records, 10 potentially contaminated sites were identified within 1,500 feet of the construction work areas. These sites are summarized in table 4.2.3-3. Based on the distance of these sites from the proposed project area and the fact that soil and groundwater contamination either has not been reported or has been cleaned up for each facility, NorthernStar does not expect to encounter contamination from these sites during pipeline construction.

While the majority of the sites identified are at such a distance that they would not affect construction, there is potential to encounter unknown aspects of the identified sites or new areas of contamination. Therefore, we have recommended that NorthernStar prepare a *Plan for the Discovery and Management of Contaminated Soils and Groundwater* that specifies the procedures to be followed to identify, characterize, and properly manage potentially contaminated materials (see section 4.2.2.1).

4.7.3.6 Recreation, Public Interest, and Special Use Areas

The Bradwood Landing pipeline would not affect any Indian reservations, or federally designated wild and scenic rivers. Several recreation and public interest areas are located near the proposed pipeline facilities.

Designated Recreation and Public Interest Areas

Special interest areas administered by federal, state, or local agencies that would be in the vicinity of or crossed by the proposed pipeline are listed in table 4.7.3-8.

Description	MP	Length of Crossing (miles)	Distance from Pipeline Centerline (feet)	Distance from Construction Workspace (feet)	Construction Impacts (acres)	Operational Impacts (acres)
Bradley State Scenic Viewpoint	1.7	NA	1,000	935	NA	NA
Ducks Unlimited Waterfowl Management Area	6.0	2.1	NA	NA	27.9	12.8
Jones Beach	9.0	NA	1,111	1,056	NA	NA
Port of Portland	9.3	0.2	NA	NA	2.4	1.0
Port of St. Helens	16.9	2.1	NA	NA	26.0	13.0
LCNHT and Lower Columbia River Water Trail	19.0	NA	0	0	NA	NA
JBHNR	19.0	NA	2,000	1,935	NA	NA
State of Washington, Department of State Lands ^a	19.6	<0.1	NA	NA	0.3	0.1
	21.1	<0.1	NA	NA	0.4	0.2
	34.2	<0.1	NA	NA	0.2	0.1
City of Longview	28.5	NA	130	95	NA	NA
^a The acreages of State of Washington, Department of State Lands are estimates. As part of the process of obtaining an easement from the WDNR, NorthernStar would be required to complete a survey, conducted by a Washington state licensed surveyor, of each waterbody that would be affected by the pipeline to determine the amount of state-owned aquatic land that would be affected.						
NA Not applicable.						

Bradley State Scenic Viewpoint

The Bradley State Scenic Viewpoint, a roadside park administered by the Oregon Parks and Recreation Department, is approximately 1,000 feet west of MP 1.7 of the proposed pipeline. No direct impacts on the Bradley State Scenic Viewpoint are anticipated as the pipeline route is not within the park's boundary. Indirect visual impacts are discussed in section 4.7.3.7.

Ducks Unlimited Waterfowl Management Area

Between approximate MPs 6.0 and 8.1, the proposed pipeline route would cross private property managed by Ducks Unlimited as a waterfowl management area. NorthernStar has consulted with the landowner and the Ducks Unlimited land manager regarding the proposed Bradwood Landing pipeline (Karamanos, 2005; Lobdel, 2005). According to the landowner, Ducks Unlimited is funding the establishment of more wetland habitat with ponds over a 35-year period. The Ducks Unlimited land manager indicated that there is a recorded agreement for the 275 acres on the western portion of the property with federal monies being spent over a period of 25 to 30 years. Ducks Unlimited is in the process of negotiating a conservation easement on an additional portion of the land with the owner for the same purposes. NorthernStar has stated it is consulting with the owner regarding the use of portions of the remaining property as the Peterson Point Mitigation Site (see section 4.5.2.2).

NorthernStar has stated that construction activities would be planned to occur from March to September at a time when waterfowl would least likely inhabit the property. Further, NorthernStar would continue to coordinate with the landowner and Ducks Unlimited before construction activities to identify and address their concerns.

Jones Beach

Jones Beach is on land owned by the ODSL on the southern shore of the Columbia River, between Wauna and Clatskanie, at about CRM 47. The beach has been created out of dredged sand piles, deposited by the COE during its maintenance of the navigation channel. It has no developed facilities, except for a parking lot. The beach is used for recreation by ORV drivers. The Lower Columbia River Water Trail can be accessed from Jones Beach. The river at this location is also used by windsurfers and kite surfers. The proposed pipeline would be about 0.2 mile from Jones Beach, and should have no impacts on the beach, its visitors, and river users in this area.

Julia Butler Hanson National Wildlife Refuge

The pipeline at MP 19 would be within about 2,000 feet east of the JBHNR at Crims Island. NorthernStar would cross under the Columbia River using the HDD method in this area, thus avoiding any direct impacts on the refuge. Additional information on the JBHNR is provided in sections 4.5.2.3 and 4.6.

Lewis and Clark National Historic Trail

The LCNHT follows the lower Columbia River. The Lewis and Clark expedition of 1805-1806 camped in the vicinity of the proposed pipeline, near Cape Horn on the Washington side of the river, near the mouth of the Clatskanie River in Oregon, and on either Walker or Dibblee Island. However, none of the Lewis and Clark campsites in the project area have been definitely relocated, or recorded as archaeological sites. The Bradwood Landing pipeline would cross the LCNHT along the Columbia River near MP 19. The pipeline would cross under the river at this location using an HDD. Potential project impacts on the LCNHT are discussed in section 4.9.

Lower Columbia River Water Trail

The proposed pipeline would cross the Columbia River using an HDD starting from the Oregon side at about MP 19. Therefore, the pipeline would have no impacts on the Lower Columbia River Water Trail.

Other Lands

The pipeline route would also cross state and local lands. These include the Port of Portland (MP 9.3), the Port of St. Helens (MP 16.9), and State of Washington lands (MPs 19.6, 21.1, and 34.2). Also, the City of Longview is located within 130 feet of the pipeline MP 28.5. Furthermore, the states own submerged lands crossed by the pipeline. For Washington, the amount of state-owned aquatic land that the pipeline would affect at the Columbia and Cowlitz Rivers would be determined at the time a survey of each waterbody is completed by a Washington state licensed surveyor. NorthernStar would be required to complete this survey as part of the process of obtaining an easement from the WDNR, which is generally one of the last steps in the permitting and licensing process. At this time, only estimates of acreage impacts can be provided, subject to change once the aforementioned surveys of both crossings are completed (Ellis, 2008). NorthernStar would obtain the appropriate authorizations to use or cross these

areas in accordance with applicable regulations. Impacts associated with the pipeline would be temporary and there would be no long-term or adverse impacts on these areas.

General Recreation and Special Uses

Much of the general recreation and special use of the area that would be affected by the proposed pipeline facilities is similar to that described for the LNG terminal. These uses include sightseeing, wildlife viewing, hiking, swimming, camping, and picnicking activities. The primary impact associated with construction of the project would be visual. Construction would alter visual aesthetics by removing existing vegetation and disturbing soils. Construction would also generate dust and noise, which could be a nuisance to recreational users. Construction could also interfere with or diminish the quality of the recreational experience by affecting wildlife movements or disturbing trails. In general, impacts on recreation and special interest areas would be temporary and would be limited to the period of active construction, which typically would last only several days to several weeks in any one area. NorthernStar would minimize construction-related impacts on these areas by installing its pipeline adjacent to existing rights-of-way to the extent possible, ensuring effective post-construction reclamation of the right-of-way to preconstruction conditions, and coordinating construction activities with land management agencies so that they occur outside of the primary recreation and special use periods (e.g., after harvest, during months when waterfowl are least likely to occupy an area).

The Clatskanie City Park is located about 2.5 miles south of the proposed pipeline (MP 13.4) and is the site of an annual bluegrass festival, which is held in August. In addition, the park has a swimming pool, sport playing field, an indoor skate park, playgrounds for younger children, horse arena, picnic tables, barbecue facility, restrooms, recreational vehicle (RV) hook-ups and facilities for camping, canoeing, paddle boating, and a boat ramp.

The Cities of Longview and Kelso, Washington are located about 4 miles south of the proposed pipeline. Recreational and tourist attractions within Longview include an 18-hole golf course, tennis courts, baseball fields, sturgeon fishing, year-round boating, Columbia Theatre for the Performing Arts, registered historical buildings, art exhibits, lecture series, summer community concerts, as well as an annual County Fair hosting the Thunder Mountain Pro Rodeo (Cowlitz County Washington State Tourism Department, 2007). Within Kelso, recreational and tourist attractions include the Mount St. Helens Volcano and Information Center; Cowlitz County Historical Museum, and the Three Rivers Golf Course, which is the only 18-hole golf course constructed on volcanic ash from Mount St. Helens. In September, Kelso celebrates its Scottish heritage with the annual Highlander Festival. Cowlitz County owns and operates a 60-acre beach park on the north side of the Columbia River at Willow Grove.

We believe that the proposed Bradwood Landing sendout pipeline would not have any significant direct impacts on general recreational use of the project area. Regional tourism should not be significantly affected because the pipeline would be installed underground and, therefore, after the right-of-way is properly restored following construction, the pipeline should not be visible to most distant visitors. The aboveground facilities associated with the proposed pipeline would be minor.

We received comments on the draft EIS regarding the potential for the permanent pipeline right-of-way to increase accessibility for ORV use, trespassing, and vandalism. Measures that NorthernStar could utilize to protect the right-of-way from unauthorized use may include placement of berms across the right-of-way; rock redistribution and strategic placement, without making it into a challenging obstacle course; or placement of woody material removed during construction across the right-of-way to both disguise the right-of-way and serve as “vertical mulch.” Any such measures could be included in a landowners’ easement negotiation process with NorthernStar.

4.7.3.7 Visual Resources

Visual resources along the pipeline route are a function of geology, climate, and historical processes and include topographic relief, vegetation, water, wildlife, land use, and human uses and development. The vegetation along the pipeline route consists mainly of medium-to large-diameter trees on mostly rolling terrain.

NorthernStar proposes to use up to a 120-foot-wide construction right-of-way. Some areas along the pipeline route would be widened for temporary extra workspaces. Visual impacts associated with the construction right-of-way and temporary extra workspaces would include the removal of existing vegetation and the exposure of bare soils, as well as earthwork and grading scars associated with heavy equipment tracks, trenching, and machinery and tool storage. Other visual effects could result from the removal of large individual trees that have intrinsic aesthetic value; the removal or alteration of vegetation that may currently provide a visual barrier from undesirable views; or landform changes that introduce contrasts in visual scale, spatial characteristics, form, line, color, or texture.

Visual impacts would be greatest where the pipeline route parallels or crosses roads and the pipeline right-of-way may be seen by passing motorists, on residents where vegetation used for visual screening of existing utility rights-of-way would be removed, and in forested areas. The duration of visual impacts would depend on the type of vegetation that is cleared or altered. The impact of vegetation clearing would be shortest in agricultural, range, and open lands, where the reestablishment of vegetation following construction would be relatively fast (generally less than 5 years).

The visual impacts would be greater in forest land, which would take many years to regenerate mature trees. The greatest potential visual impact would result from the removal of large specimen trees, which would take longer than other vegetation types to regenerate and would be prevented from reestablishing on the permanent right-of-way. The establishment of a new pipeline right-of-way through these forested areas would create a permanent visual impact. Although the temporary portion of the construction right-of-way would be allowed to revert to preconstruction conditions, the new permanent right-of-way would be maintained in an herbaceous state. NorthernStar's restoration plan calls for the planting of in-kind trees outside of a 30-foot-wide corridor centered on the pipeline within the cleared construction right-of-way that is presently forest. Also, in forested wetlands, the right-of-way would be replanted with in-kind wetland tree specimens, with the exception of the portion of the right-of-way within 5 feet of the pipeline (10 feet total), thereby minimizing the extent of disturbance. Nearly complete canopy coverage over the pipeline would be expected to develop in most forested upland and forested wetland areas within approximately 20 years. In general, visual contrasts in forested areas would be noticeable primarily from road crossings and the scattered rural residences. Several major roads would be crossed by the pipeline. Therefore, many motorists would be visually aware of pipeline construction and would notice permanent tree removal to accommodate the permanent right-of-way.

About 22 percent of the Bradwood Landing pipeline would be located adjacent to the existing KB pipeline right-of-way. Construction within or adjacent to existing rights-of-way typically reduces impacts on visual resources because it minimizes vegetation clearing. However, a degree of permanent clearing still must occur to properly maintain and operate a pipeline right-of-way. Vegetation would be cleared during construction of the Bradwood Landing pipeline and would result in both short-term and long-term impacts on visual resources depending on the type of vegetation that is removed. NorthernStar would maintain its permanent right-of-way in an herbaceous state.

Revegetation of the right-of-way is an important mitigation measure that would be used to reduce visual impacts of pipeline construction and operation. NorthernStar would monitor and measure

revegetation success in accordance with the FERC's guidelines for proper establishment of the desired species and weed control.

Construction of the pipeline would result in indirect visual impacts on the Bradley State Scenic Viewpoint, located approximately 1,000 feet west of MP 1.7. Between MPs 0.0 and 1.3, the pipeline would be installed using the HDD method to reduce impacts on the Bradwood Cliffs and associated forest. Since the proposed Bradwood Landing pipeline would be located at the base of the hill east of the Bradley State Wayside viewpoint, and would only occupy a 50-foot-wide permanent right-of-way once it is permanently restored, NorthernStar does not anticipate a major impact on the view. The proposed pipeline right-of-way through most of the forested area would not be seen from the Bradley State Scenic Viewpoint because the ridge blocks the view. Where the right-of-way is closer to the Wauna Mill, the right-of-way follows existing roads or cleared areas. A stretch of the right-of-way south of the paper mill is forested near the Wauna Mill's landfills. At the end of construction, the right-of-way would look similar to many of the access roads on the Wauna Mill property.

All affected permanent and temporary workspace visible from the Bradley State Scenic Viewpoint is zoned Forest 80. By definition, all Forest 80-zoned property is subject to harvest under the guidelines established by the Oregon Department of Forestry, including its jurisdiction over the harvesting of the trees involved with NorthernStar's pipeline right-of-way. Therefore, removal of forest land to accommodate the permanent right-of-way would not be inconsistent with tree removal allowed by state zoning.

Construction and operation of the new aboveground facilities associated with the Bradwood Landing pipeline would have a permanent impact on visual resources. However, none of these sites are located in areas identified as having any special or unique scenic characteristics or in areas with any designated protection for scenic values. The facilities would be located in industrial areas, or in rural areas with generally moderate to low scenic values that are not sensitive to visual resource changes due to a low number of potential viewers. However, construction and ground disturbances would be noticeable to viewers in the vicinity of these activities. Permanent structures would be relatively small and, as such, would remain subordinate to the visual landscape in which they would be located. Further, NorthernStar would paint the meter stations a non-reflective color that would blend with the surrounding landscape, the use of which would reduce the visual impacts associated with operation of the aboveground facilities.

4.8 SOCIOECONOMICS

The Bradwood Landing Project includes the construction and operation of an LNG import terminal in Clatsop County, Oregon and a 36.3-mile-long natural gas sendout pipeline that would cross through portions of Clatsop and Columbia Counties, Oregon and Cowlitz County, Washington. Therefore, most of the project-related socioeconomic impacts would occur within these counties. However, socioeconomic effects relating to construction of the project would also extend into the Portland-Vancouver-Beaverton, Oregon-Washington, Metropolitan Statistical Area (Portland MSA), where approximately 75 percent of the construction workforce for the LNG terminal and 86 percent of the construction workforce for the pipeline are expected to reside. Columbia County is one of seven counties included in the Portland MSA; therefore, overlap will occur when discussing potential socioeconomic impacts on these areas. Socioeconomic effects relating to LNG marine traffic during operation of the LNG terminal could also extend into Wahkiakum and Pacific Counties, Washington.

Several potential socioeconomic effects may result from construction and operation of the proposed Bradwood Landing Project. Many of these potential effects would occur during the construction phase and would result from the number of local and non-local construction workers who would work on the project; their income and local expenditures; and their impact on traffic flow, population, housing, and public services. Other potential impacts are related to operation of the project, such as LNG marine traffic along the lower Columbia River and its effects on other river users. Operation of the project would have impacts on the local economy, including increased property tax revenue, increased job opportunities and income, and ongoing local expenditures by NorthernStar.

The potential impacts of the project on land use and residences in the vicinity of the project are discussed in section 4.7. A discussion of the cumulative impacts of the Bradwood Landing Project when considered with other proposed or reasonably foreseeable future projects is included in section 4.12.

4.8.1 Waterway for LNG Marine Traffic

As described above, socioeconomic effects related to LNG marine traffic along the waterway would potentially impact Wahkiakum, Pacific, and Cowlitz Counties in Washington and Clatsop County in Oregon. Within these counties, the communities of Warrenton and Astoria, Oregon and Ilwaco, Cathlamet, and Puget Island, Washington have over 500 people residing there.

4.8.1.1 Population

Table 4.8.1-1 provides a summary of population statistics for the three counties and communities with populations over 500 along the waterway. With the exception of Ilwaco, at least a portion of each of the communities in this table would be within the Zones of Concern during LNG carrier transit up the Columbia River. The counties affected by the Bradwood Landing Project vary in their population totals and densities. Clatsop County, Oregon has a population density higher than the average for the State of Oregon. The highest population density occurring along the waterway is within the City of Astoria, with 1,597.6 persons per square mile. The lowest population density occurring along the waterway is within Wahkiakum County, with an average of 14.5 persons per square mile. However, during the tourist season, population in some communities can more than double (ODE, 2006).

TABLE 4.8.1-1					
Existing Population in the Counties and Communities Along the Waterway for LNG Marine Traffic					
State/County/Community	Population			Population Density ^a	
	1990	2006	Percent Change	1990	2006 ^b
Oregon	2,842,321	3,700,758	30.2	29.6	38.6
Clatsop County	33,301	37,315	12.1	40.3	45.1
Astoria (CRM 14) ^{b c}	10,069	9,813	-2.6	1,766.5	1,597.6
Warrenton (CRM 10) ^c	2,681	4,096	52.8	160.5	332.2
Washington	4,866,692	6,395,798	31.4	73.1	96.1
Pacific County	18,882	21,735	15.1	19.4	22.3
Ilwaco (CRM 3) ^c	815	950	16.6	388.1	452.4
Wahkiakum County	3,327	4,026	21.0	12.6	15.2
Cathlamet (CRM 39) ^c	508	565	11.2	1,270.0	1,426.2
Puget Island (CRM 38) ^c	734	798	8.7	97.9	106.4
^a Persons per square mile based on population and land area size: Oregon (95,997 square miles), Clatsop County (827 square miles), Astoria (5.7 square miles), Warrenton (16.7 square miles), Washington (66,544 square miles), Pacific County (975 square miles), Ilwaco (2.1 square miles), Wahkiakum County (264 square miles), Cathlamet (0.4 square mile), and Puget Island (7.5 square miles).					
^b Information from the U.S. Census Bureau includes the community of Navy Heights (population of 627 persons) as part of the City of Astoria.					
^c Census Bureau 2006 data not available. Data from U.S. Census Bureau, 2000 Census data.					
Sources: U.S. Census Bureau, American Population, Housing Units, Area, and Density, 1990. U.S. Census Bureau, State and County Quickfacts, 2006.					

No changes to the local population distribution or number are expected to occur as a result of the proposed LNG marine traffic. However, the population within the Zones of Concern along the waterway could be affected due to an accidental or intentional breach of an LNG carrier resulting in a release of LNG during transit to the LNG terminal. The severity of impacts on populations in Zones 1-3 would depend on the location of the incident relative to the population, the scope of the incident, and whether the released LNG ignited or evaporated. Impacts from a pool fire would be most severe in Zone 1 and decreasing outward through Zones 2 and 3. However, with the implementation of the safety and security measures and conditions outlined in the Coast Guard's WSR (see Appendix G), an LNG release along the waterway would be highly unlikely and the potential impact on the area population would be less than significant.

4.8.1.2 Housing

Housing statistics for the counties and communities larger than 500 persons along the waterway, are presented in table 4.8.1-2. A total of 10,116 vacant housing units occur in the counties along the waterway. Within the communities considered, vacancy rates ranged from a low of 32 available units in Cathlamet, Washington to a high of 623 units in Astoria, Oregon.

At Astoria, there are five hotels or motels (Cannery Pier Hotel, Astoria Rivershore Motel, Lamplighter Motel, Holiday Inn Express, and the Dunes Motel), with a total of 253 rooms combined, overlapped by Zone 1. Within Zone 2 in Astoria are seven hotels or motels (Hotel Elliott, Hideaway Inn and Hostel, Best Western, Red Lion Inn, Comfort Suites, Fisherman Suites, and Paradise Home Stay), with a combined total of 333 rooms.

TABLE 4.8.1-2				
Housing Characteristics in the Counties and Communities Along the Waterway for LNG Marine Traffic				
State/County/MSA	Total Housing Units	Total Vacant Housing Units	Vacancy Rate (percent)	Median Gross Monthly Rent
Oregon	1,452,709	118,986	8.2	\$620
Clatsop County	19,685	4,982	25.3	\$543
Astoria ^a	4,858	623	12.8	\$519
Warrenton	1,799	178	9.9	\$561
Washington	2,451,075	179,677	7.3	\$663
Pacific County	13,991	4,895	35.0	\$483
Ilwaco	524	108	20.6	\$565
Wahkiakum County	1,792	239	13.3	\$519
Cathlamet	278	32	11.5	\$395
Puget Island	404	72	17.8	\$783

^a Information from the U.S. Census Bureau includes the community of Navy Heights (population of 627 persons) as part of the City of Astoria.

Source: U.S. Census Bureau, 2000.

LNG marine traffic should not result in significant changes in demand for housing in the communities along the waterway. The lower Columbia River is already used by almost 2,000 commercial ships per year. Residential structures and hotels within the Zones of Concern along the waterway could be affected in the event of an accidental or intentional breach of an LNG carrier resulting in a release of LNG and an associated fire. As discussed further in section 4.11.5, if a pool fire occurred where the transit route is close to shore, structures within 2,200 feet of the center of a spill could be subject to a long-term loss of use. However, with the implementation of the safety and security measures and conditions outlined in the Coast Guard's WSR, an LNG release along the waterway would be highly unlikely and the potential impact on housing would be less than significant.

4.8.1.3 Property Values

In 2005, the total assessed value of real property in Pacific County, Washington was \$1,633,127,590, while the total assessed value of real property in Wahkiakum County, Washington was \$277,859,240 (Workforce Explorer, 2007). The total real market value of assessed property in Clatsop County, Oregon in the fiscal year 2005 to 2006 was \$5,438,799 (Oregon Department of Revenue, 2007). In 2005, the estimated median value of a house in Warrenton was \$147,200, in Astoria it was \$153,500, and in Cathlamet it was \$122,900 (City Data, 2007).

Currently, almost 2,000 commercial ships per year using the Columbia River navigation channel pass by the communities along the river shore in Pacific and Wahkiakum Counties, Washington, and Clatsop County, Oregon. If the proposed LNG terminal goes into operation, commercial river traffic would increase by about 7 percent (Parsons Brinckerhoff, 2005). We do not believe that this slight increase in commercial river traffic would have any negative impacts on property values in communities along the waterway. We are unaware of any studies that have been done relative to the effects on property values due to the potential hazards of LNG marine traffic, and none have been filed with the FERC. With implementation of the safety and security measures and conditions outlined in the Coast Guard's WSR, it is highly unlikely that there would be an incident involving an LNG carrier using the waterway that would affect adjacent property values.

4.8.1.4 Economy and Employment

Table 4.8.1-3 provides a summary of existing economic conditions in counties and communities along the waterway. According to the U.S. Census Bureau (2000), the top industries in the areas along the waterway include education, health, and social services. Reflecting the level of tourism in these communities, arts, entertainment, recreation, accommodation and food services, and retail trade comprise a large percentage of employment in Astoria and Warrenton, respectively. The top employer in two of the three affected counties is a forestry or wood products company, reflecting the continued importance of forestry in the region. According to the Clatsop County Community Profile, the county's top employers include the Georgia-Pacific pulp and paper mill, state and local governments, and the Coast Guard (Clatsop County, 2005). Pacific County's top private employer is Coast Seafoods (Pacific County Economic Development Council, 2007). In Wahkiakum County, Jerry DeBriar Logging Company, Wahkiakum County, and Wahkiakum County School District are the top employers (Lower Columbia Economic Development Council, 2005).

TABLE 4.8.1-3				
Existing Economic Conditions in the Counties and Communities Along the Waterway for LNG Marine Traffic				
State/County/ Community	Per Capita Income (2000)	Civilian Labor Force (2000)	Unemployment Rate (percent) (2006)	Top Industries by Employment (2000)
Oregon	\$20,940	1,740,298	5.4	Education, Health and Social Services (19.3%) Manufacturing (14.4%)
Clatsop County	\$19,515	17,656	5.0	Education, Health and Social Services (19.2%) Arts, Entertainment, Recreation, Accommodation, and Food Services (15.7%)
Astoria ^a	\$18,759	4,796	6.9	Education, Health and Social Services (22.0%) Arts, Entertainment, Recreation, Accommodation, and Food Services (14.1%)
Warrenton	\$16,874	1,933	3.7	Education, Health and Social Services (19.3%) Retail Trade (18.6%)
Washington	\$22,973	2,979,824	5.0	Education, Health and Social Services (19.4%) Manufacturing (12.5%)
Pacific County	\$17,322	8,663	6.6	Education, Health and Social Services (21.3%) Arts, Entertainment, Recreation, Accommodation, and Food Services (12.6%)
Ilwaco	\$16,138	435	6.4	Education, Health and Social Services (23.3%) Arts, Entertainment, Recreation, Accommodation, and Food Services (12.3%)
Wahkiakum County	\$19,063	1,691	6.5	Education, Health and Social Services (24.6%) Agriculture, Forestry, Fishing and Hunting, and Mining (14.6%)
Cathlamet	\$18,588	216	9.7	Education, Health and Social Services (29.7%) Agriculture; Forestry; Fishing and Hunting; and Mining (11.3%) Public Administration (11.3%)
Puget Island	\$22,444	374	8.0	Education, Health and Social Services (29.1%) Manufacturing (12.2%)
^a Information from the U.S. Census Bureau includes the community of Navy Heights (population of 627 persons) as part of the City of Astoria. Sources: U.S. Census Bureau, Profile of Selected Economic Characteristics, 2000. U.S. Department of Labor, Bureau of Labor Statistics. Local Area Unemployment Statistics, 2006.				

Within the counties and communities along the waterway, average per capita income was slightly lower than the averages for Oregon and Washington. In 2006, Warrenton and Clatsop County, Oregon had unemployment rates lower than the state average of 5.4 percent. The remaining counties and communities along the waterway had unemployment rates higher than state averages, ranging from 6.4 percent within Ilwaco, Washington to 9.7 percent within Cathlamet, Washington.

LNG marine traffic could have beneficial impacts on the economy of the counties along the waterway. NorthernStar would have to rent at least three tugboats, and pay their crews, to escort each LNG carrier. This is discussed in section 4.8.1.7. The economy in the area could be affected in the unlikely event of an accidental or intentional breach of an LNG carrier resulting in a release of LNG. If a pool fire occurred where the transit route is close to shore, businesses within 2,200 feet of the center of a spill could be subject to a long-term loss of use. However, because the hazard area surrounding an LNG cargo vessel is transient (moving with the vessel along its route), it is not possible to accurately quantify the economic impact of an incident. Also, given the precipitation in the region, any project-related fire would likely be of short duration and limited extent. Nevertheless, with the implementation of the safety and security measures and conditions outlined in the Coast Guard's WSR, an LNG release along the waterway would be highly unlikely and the potential impact on the economy and employment would be less than significant.

4.8.1.5 Tax Revenues

The tax revenues generated by the Bradwood Landing Project would be associated with construction and operation of the LNG terminal and pipeline facilities themselves, and not with the LNG carriers. Therefore, LNG marine traffic along the waterway would not affect tax revenues in the area.

4.8.1.6 Local Infrastructure and Public Services

Information on existing public services in the area of the waterway for LNG marine traffic is provided in table 4.8.1-4. Warrenton, Astoria, and Cathlamet are incorporated cities within the Zones of Concern along the waterway for LNG marine traffic. The other communities listed on table 4.8.1-4 are within approximately 30 miles of the waterway and provide public services to the region.

Warrenton, Oregon was incorporated in 1899. The city government includes an administrative office run by a City Manager, a finance department, planning department, fire and police departments, municipal court, and department of public works. The City of Astoria is the county seat for Clatsop County, Oregon. The Astoria city government is administered by a City Manager, and includes departments of finance, public works, fire, police, community developments, and parks and recreation. Astoria has a port authority that operates an airport and several marinas. Northwest Natural provides natural gas and Pacific Power provides electricity to Warrenton and Astoria.

The town of Cathlamet, Washington, which is the county seat for Wahkiakum County, was incorporated in 1907. The town government is directed by a Mayor and Council. Town employees include a treasurer, clerk, public works supervisor, attorney, and librarian. There is a Fire Department, Public Works Department, Planning Commission, and Library Board, and the town operates parks and recreational facilities. The town manages a water treatment plant and sewer system, but its main source of water comes from the Wahkiakum County Public Utilities District No. 1, which also provides electricity. Natural gas is not currently available in Cathlamet (Town of Cathlamet, 2007; Lower Columbia Economic Development Council, 2007).

TABLE 4.8.1-4

Existing Public Services in the Vicinity of the Bradwood Landing Project

Facility	Location	Details
Hospitals	Astoria	Columbia Memorial Hospital Level III Trauma Center with 49 beds
	Cathlamet	Wahkiakum Family Practice Clinic Outpatient Treatment
	Ilwaco	Ocean Beach Hospital 15 beds
	Longview	St. Johns Medical Center Level III Trauma Center with 193 beds
	Seaside	Providence Seaside 22 extended care beds, 34 acute care beds
	St. Helens	St. Helens Lab Outpatient Treatment
Ambulance Services	Astoria	Medix Ambulance
	Clatskanie	Clatskanie Ambulance
Fire Departments	Columbia	Columbia River Fire and Rescue 7 stations in Columbia County
	Cowlitz County	Cowlitz County Fire Protection District #2 Serving the Kelso/Longview area
	Cowlitz County	Cowlitz County Fire Protection District #6 Serving the Castle Rock area
	Astoria	Astoria Fire Department
	Astoria	Lewis and Clark Rural Fire Protection District (RFPD)
	Astoria	Olney Walluski Fire and Rescue
	Astoria	John Day-Fernhill RFPD
	Clatskanie	Clatskanie RFPD
	Gearhart	Gearhart RFPD
	Knappa	Knappa-Svensen Burnside RFPD
	Longview	Longview Fire Department
	Seaside	Seaside Fire and Rescue
	Warrenton	Warrenton Fire Department
	Westport	Westport Wauna Fire District
Law Enforcement	Clatsop County	Clatsop County Sheriff's Office 60 officers
	Columbia County	Columbia County Sheriff's Department 6 police officers
	Cowlitz County	Cowlitz County Sheriff's Office 48 commissioned deputies
	Wahkiakum County	Wahkiakum County Sheriff's Office 8 officers
	Astoria	City of Astoria Police Department
	Clatskanie	Clatskanie Police Department 5 police officers
	Columbia	Columbia City Police Department 7 police officers
	Castle Rock	Castle Rock Police Department
	Kelso	Kelso Police Department
	Longview	Longview Police Department
	Svensen	Svensen Sheriff Station
	St. Helens	St. Helens Police Department 18 police officers

There are structural elements of the local infrastructure within the communities along the waterway for LNG marine traffic that are overlapped by the Zones of Concern. At about CRM 5, Zone 3 overlaps with the Coast Guard Cape Disappointment Station mooring on the north shore of the Columbia River in Pacific County, Washington.

The former town of Hammond has been merged into the City of Warrenton, in Clatsop County, Oregon. The City of Warrenton covers 17 square miles, and is responsible for the southern shoreline of the Columbia River from Clatsop Spit (Buoy 14) east to Smith Point. At about CRM 11, the Hammond Boat Basin and the Youngs Bay Bridge along Highway 101 are within Zone 2. Within Zone 3 is the Warrenton police and fire departments, the Warrenton-Astoria Regional Airport, including the Coast Guard Air Station (about 3,700 meters south of the navigation channel), and the Warrenton Marina.

The City of Astoria, in Clatsop County, Oregon, is located between about CRMs 13 and 14. Within Zone 1 at Astoria is Pier 1, where cruise ships berth; Pier 2, serving the bulk of the local commercial fishing fleet, and recreational boating facilities at the West Basin and East Basin marinas and the 17th Street dock, operated by the Port of Astoria; the Astoria-Megler Bridge over the Columbia River along Highway 101; the Astoria police and fire departments and emergency information center; the Columbia River Maritime Museum; the riverfront trolley; and boat anchorages. Within Zone 2 at Astoria is Captain Robert Gray Elementary School, with 780 students (1,100 meters south of the navigation channel); John Jacob Astor Elementary School, with 298 students (1,200 meters south of the navigation channel); Clatsop Care Center; Columbia Memorial Hospital (1,200 meters south of the navigation channel); Clatsop County Health and Human Services; and the Coast Guard base at Tongue Point. Within Zone 3 at Astoria is Astoria Middle School, with 550 students (1,900 meters south of navigation channel) and Astoria High School, with 760 students (1,700 meters south of the navigation channel).

At about CRM 33, the Wahkiakum County Fire Protection District No. 2 in Skamokawa, Washington is overlapped by Zone 1. There is also a town center in Skamokawa.

In Cathlamet, Washington, at about CRM 39, the Wahkiakum County Fire Protection District No. 1, the town of Cathlamet fire department, and town hall are overlapped by Zone 3.

In review of NorthernStar's WSA, the Coast Guard identified resource gaps that exist in the ability of local emergency services, including police and fire departments, to respond to a potential incident involving an LNG carrier in the waterway. The Coast Guard has outlined conditions in its WSR that must be met in order to have the waterway found suitable for LNG marine traffic (see Appendix G). In addition, the ODE requested that the FERC require NorthernStar to fill emergency response gaps in Clatsop County. On March 24, 2008, NorthernStar filed its first draft ERP. In accordance with the EAct, the ERP must offer a cost-sharing plan, and outline how NorthernStar would fill resource gaps and supplement the first-responder capabilities of the local jurisdictions. As discussed further in section 4.11.6, we will require NorthernStar to file a final ERP for review and approval by the Director of OEP prior to the beginning of project construction activities.

4.8.1.7 Transportation and River Traffic

The main road systems along the waterway include Washington State Route 4 running east-west parallel to the lower Columbia River on the north side in Washington, and Oregon State Route 30 running east-west on the south side of the river in Oregon. U.S. Highway 101 runs south-north between Warrenton, Oregon and Ilwaco, Washington, crossing the Columbia River from Astoria, Oregon to Point Ellice, Washington. The Zones of Concern overlap Highway 101, including the Youngs Bay Bridge at Warrenton, and the Astoria-Megler Bridge over the Columbia River at about CRM 13, and a portion of Washington State Route 4 near Cathlamet, and Oregon State Route 30 south of Bradwood and at Astoria.

In the unlikely event of an LNG carrier accident that results in a spill and associated pool fire, these roads may be affected. However, we believe that with the implementation of the conditions outlined in the Coast Guard's WSR, the likelihood for such impacts is extremely remote.

About 2,000 commercial ships per year use the Columbia River navigation channel to reach upriver ports. In 2007, 18 cruise ships docked at Astoria and 19 cruise ships are scheduled to call in 2008. Table 4.8.1-5 includes the totals of the various commercial vessel types that used the river in 2004, 2005, and 2006. In addition, several smaller river cruise vessels travel between Portland and Astoria that could be affected by passage of the LNG carriers associated with the proposed project. However, we expect that impacts on these smaller vessels would be similar to the impacts on other recreational river users as discussed in section 4.8.1.8.

TABLE 4.8.1-5					
Density and Type of the Shipping Marine Traffic on the Columbia River					
Vessel Type	2004	2005	2006	Total	Daily 3-Year Average
Container vessels	198	94	140	432	0.39
Tankers	163	137	188	488	0.45
Car carriers	247	267	344	858	0.78
Bulkers	780	795	733	2,308	2.11
General Cargo (includes log ships)	244	218	252	714	0.65
Others (includes barges, naval, etc.)	76	76	57	209	0.16
Ocean-going cruise Ships	20	24	26	70	0.06
Total	1,728	1,611	1,740	5,079	

In accordance with the Coast Guard's guidance in the NVIC-05-05, NorthernStar prepared a WSA to address potential impacts of its proposal on other waterway users. The Coast Guard validated the WSA, and issued a WSR in February 2007 (see Appendix G). The conditions outlined in the WSR are discussed in section 4.11.5.5. After the completion of the final EIS, the Coast Guard will complete its review and issue an LOR to address the suitability of the waterway for LNG marine traffic. A discussion of safety issues related to LNG marine traffic is included in section 4.11.5. Impacts on recreational activities on the Columbia River are discussed in section 4.7.1.4.

NorthernStar indicated that about 125 LNG carriers per year would travel along the navigation channel in the Columbia River to the LNG terminal at Bradwood. As discussed in section 2.1.1, the LNG carriers could range in capacity from 100,000 to 200,000 m³, although the Coast Guard would limit the size of the LNG carriers to a maximum capacity of 148,000 m³ until additional risk analyses addressing larger vessels have been completed (see section 4.11.5). Typically, LNG carriers would be up to 1,000 feet long, have drafts of about 40 feet deep, and travel at a speed of up to 12 knots in the waterway.

We do not believe that LNG carriers transiting in the waterway to and from the proposed Bradwood Landing terminal would be significant impediments to other river traffic. They would represent only a minor increase in current totals for commercial ship traffic. This is more fully discussed below. In addition to the potential impacts discussed below, an incident that results in an LNG spill from a carrier in the waterway would affect other commercial traffic in the lower Columbia River. However, with the implementation of the safety and security measures and conditions outlined by the Coast Guard in its WSR, we believe that an LNG release along the waterway would be highly unlikely and the potential impact on transportation and river traffic would be less than significant.

Shipping

Other ship traffic using the navigation channel of the Columbia River at the same time that an LNG carrier is transiting the waterway to the terminal may be affected by the conditions outlined in the Coast Guard's WSR. These conditions include:

- establishment of a 500-yard moving safety and security zone around the LNG carrier while it is underway or at anchor on the Columbia River and a 200-yard fixed security zone while the LNG carrier is moored at the LNG terminal; and
- one-way traffic when meeting an LNG carrier along certain portions of the waterway, such as at turns along the Columbia River.

The 200-yard fixed security zone while the LNG carrier is moored at the LNG terminal was designed to minimize impacts on other vessels while ensuring adequate protection of the LNG carrier (see figure 4.8.1-1). It should be noted that the Coast Guard's moving safety/security and moored vessel security zones would not be treated as absolute exclusion zones that would preclude all other vessel movements. Rather, other vessels may be allowed to transit through the moving safety/security and moored vessel security zones with the permission of the COTP. The expectation is that the COTP's Representative would work with the pilots and patrol assets to control traffic, and would routinely allow vessels to transit the safety/security zone based on a case-by-case assessment conducted on scene.

Although one-way traffic would be imposed along certain portions of the waterway during the LNG carrier transit, four passing zones along the transit route would allow two-way traffic. The passing zones are based on informal best practices currently used by deep-draft traffic. The meeting and overtaking of vessels is coordinated by river pilots using their VTIS system and bridge-to-bridge communication. Through careful traffic management, prearrangement of meeting locations, and an expanded vessel traffic information system, traffic delays are expected to be negligible, as the traffic patterns are designed to resemble those already in use by deep-draft traffic today. Overtaking an LNG carrier would be prohibited; however, due to the relative speed of an LNG carrier, and with vessel traffic planning, it is extremely unlikely this prohibition would result in any measurable delays.

A marginal increase in ship traffic could occasionally increase the wait time for ships in Astoria. If a large number of ships arrive at the mouth of the Columbia River in a short time period, some may need to wait for a pilot. A similar scenario plays out just upriver of Astoria when bar and river pilots replace one another.

NorthernStar filed an analysis of vessel arrival patterns at the mouth of the Columbia River, to determine the potential for navigational conflicts LNG carrier traffic may have with other commercial ships traversing the Columbia River bar. LNG carriers are expected to cross the bar within a 3-hour window prior to high tide. The study found that about half the time, arriving LNG carriers would encounter no other commercial vessels while crossing the bar during the 3-hour tidal window. The maximum number of other commercial vessels that may be encountered by an arriving LNG carrier at the mouth of the Columbia River would be four. Almost 80 percent of the time, there would be no delays for LNG carriers crossing the bar due to other traffic. However, 20 percent of the time the average delay at the bar for an LNG carrier due to other traffic would be about 26 minutes. In one case, an arriving LNG carrier would have to wait 2.23 hours to cross the bar because of a cruise ship departure.¹⁹

¹⁹ Parsons Brinckerhoff, 30 May 2007, Columbia River Navigation Channel Analysis of Vessel Arrival Patterns, filed on March 24, 2008. This document is available for viewing by the public via the FERC's Internet webpage at www.ferc.gov through the eLibrary link. Proposed LNG Terminal Site LNG Carrier Security Zone

0 750 1,500 2,250 Feet

↑

The worst case delay scenario is that another ship would be required to wait an entire tide cycle (12 hours or more). However, proactive scheduling and active communication between LNG carriers and other commercial ships could help to mitigate potential impacts. Further, because the river currently supports a high level of cargo shipping, it is anticipated that other vessels have extensive experience with ship traffic and would be adept at minimizing wait time. NorthernStar has filed a proposal for navigation protocols and priorities that would minimize delays to other commercial vessels on the lower Columbia River due to LNG carrier traffic.²⁰

In the unlikely event of an LNG spill, the physical properties of LNG would limit any potential impacts. If spilled into water, the cryogenic liquid would vaporize rapidly upon contact with the warm air and water over a period of approximately 1 to 2.5 hours. If an LNG spill occurred along the transit route, ship traffic may be temporarily interrupted in the navigation channel; however, traffic in the navigation channel would quickly resume normal operations and any economic impact on the maritime industry would be minimal.

Commercial Fishing and Indian Treaty Fishing Rights

In recent years, commercial fishing for salmon and sturgeon (the primary commercial fish) along the Columbia River has been limited to a season lasting just a few days, occasionally even hours. These seasons are regulated according to forecasted fish populations with the goal of sustaining the fishery. There is a commercial fishing fleet based out of Astoria, Oregon and Ilwaco, Washington, in addition to others located along the lower Columbia River all the way up to Bonneville Dam. In part due to their proximity to Astoria and net-pen fisheries, commercial fishing activities on the lower river are concentrated on Young's Bay and the mouth of the Columbia. At certain times, there may be a peak of up to 200 commercial fishing boats on the lower Columbia River (Kraley, 2006). There are five Select Area Fisheries Evaluation net-pen rearing and fishing sites situated between CRM 10 and 35. In 2003, returning select area fishing generated \$3,290,642.

Gill-netters on the lower Columbia River recognize, among themselves, certain "drift rights." These drift rights are held by members of associations that pool their efforts to clear particular fisheries or "drifts" of snags and debris. This membership gives the members of the drift exclusive rights to fish this area on the ebb tide. Although the drift rights are considered to be only a gentleman's agreement, a membership may be bought or sold, with the permission of the other members of the association. The drift rights allow each group of fisherman to fish in its respective area. The fish are not considered to be common property among the entire fleet; rather, they belong to the specific drift until they are either caught or move on. By contrast, in more mobile adaptations such as trolling, fish are considered common property until actually caught (Martin, 1994). However, as a matter of law, in neither Oregon nor Washington may individuals or associations obtain exclusive fishing rights in any portion of a navigable waterway, such as the Columbia River. In 1990, the Washington Supreme Court specifically rejected the claims of a gill-netter association to exclusive drift rights on the lower Columbia River, finding that "local custom and usage do not support legal recognition of drift rights." Although exclusive, location-specific drift rights are not authorized by commercial gill net licenses and do not have any legal recognition in Oregon or Washington, NorthernStar is negotiating with the claimants of such rights in areas immediately adjacent to the project site regarding potential mitigation.

LNG marine traffic in the waterway should not have significant adverse effects on commercial and gill net fishing. Commercial fishermen already take into consideration current large tanker traffic on the lower Columbia River. Project-related LNG carrier transit would increase commercial ship traffic in

²⁰ Parsons Brinckerhoff, 31 January 2007, Columbia River Navigation Channel Analysis of Navigation Protocols and Priorities, filed March 24, 2008. This document is available for viewing by the public via the FERC's Internet webpage at www.ferc.gov through the eLibrary link. Go to Docket No. CP06-365, select an appropriate date range, and look up accession number 20080325-5012.

the waterway by about 7 percent. It is expected that fishermen could encounter an LNG carrier on the river about once every 1.5 days. Fishing vessels may have to temporarily move out of the way to avoid the safety and security zones surrounding the LNG carriers during their transit upriver to the terminal. However, it is anticipated that such inconveniences would be short term, lasting only a few minutes while an LNG carrier passes at speeds between 8 to 12 knots.

Comments were received on the draft EIS regarding potential impacts of the project on Indian treaty fishing rights. Four Indian tribes exercise their treaty fishing rights for ceremonial, subsistence, and commercial purposes in the Columbia River above Bonneville Dam. No Indian treaty fishing sites have been identified along the waterway for LNG marine traffic. However, salmon migrating to and from sites above Bonneville Dam could be affected by the passage of LNG carriers during operation of the proposed project. As discussed in section 4.5.1.1, NorthernStar would avoid, minimize, reduce, rectify, and compensate for impacts on fishery resources during construction and operation of the project. Therefore, no significant adverse impacts on Indian treaty fishing rights are anticipated as a result of the proposed project.

Charter Boat Services

A charter fleet operates out of Ilwaco, Washington. Charter boat traffic in 2004 occurred primarily during the summer months and peaked during June with a daily average of 15 boats per day. Although the average daily traffic is sparse, this traffic is likely more concentrated during weekend periods. Because charter services extend beyond the mouth of the Columbia River into the open ocean, charters have extensive experience with ship traffic and are adept at minimizing its impact. For these reasons, and due to the relatively minor increase in overall ship traffic due to the project, LNG carriers would have minimal impact on charter services.

Ferry

A ferry runs between Westport, Oregon and Puget Island, Washington. The ferry is operated by Wahkiakum County and links Washington State Route 409 to Oregon Highway 30 (Wahkiakum County Commission, 2005). This ferry is located 5 miles upriver of Bradwood and would not be impacted by the Bradwood Landing Project.

Ship Piloting

The piloting grounds of the Columbia River are divided into the Columbia River Bar and the river proper. From entry into United States waters to a location in the channel off Tongue Point east of Astoria, LNG carriers would transit under the navigational control of a Columbia River Bar Pilot. LNG carriers would transit under Columbia River Pilot supervision from Tongue Point to the proposed LNG terminal. Arrival and docking operations would proceed under the supervision of the Columbia River Pilots with assistance tugs. Although NorthernStar would be responsible for payment of pilot fees, the true impact on pilotage from this project would take the form of lower tariffs for other shippers. NorthernStar would contribute approximately \$1.6 million of the fixed costs associated with pilot service. Currently, this cost is being borne by all of the other ships that use the pilots. Therefore, because of the fees paid by NorthernStar, the resulting per ship pilotage fee paid by other users would be lowered significantly, which has the potential to increase the competitiveness of the region as a shipping destination.

Currently, both piloting grounds have unused capacity. Therefore, the 7 percent increase in ship traffic associated with the proposed project could be serviced with the existing number of pilots. Although pilots would experience increased deck-time and ships serviced per pilot, additional pilots

would not be needed (Kraley, 2006). The increased deck-time per pilot may result in increased wait time for ships in Astoria occasionally. This is due to the fact that there are different pilots for the Columbia River Bar and for the Columbia River, and the pilots change just upstream of Astoria.

In a letter to the FERC dated October 10, 2005, Captain Steve Brown, President of the Columbia River Pilots, expressed the opinion that the pilots could move the LNG carriers without incident. He noted that there is nothing uniquely difficult about LNG carriers from the standpoint of safe navigation, and the pilots routinely move vessels of similar size. The pilots suggested that the LNG transits occur mostly during daylight hours during the first months of operation of the terminal, and that two pilots be assigned to each LNG carrier, as is currently the practice for large tankers carrying petroleum products.

Tugboat Operations and Long-Shoring Activities

The Coast Guard's WSR requires that each LNG carrier be escorted by a minimum of two tugs; at least one of which must be a tractor tug. A third tug would be necessary for turning and mooring to the terminal berth. NorthernStar estimated it would pay about \$1.4 million per year in tugboat rental fees, and the increased tugboat activities related to the Bradwood Landing Project would result in the hiring of approximately 40 additional employees to work on the LNG carrier escort tugboats.

4.8.1.8 Recreation and Tourism

The Zones of Concern along the waterway would overlap with state parks, local parks, national wildlife refuges, and marinas located along the shore of the Columbia River. Therefore, LNG marine traffic has the potential to affect recreational and tourist related activities. Some commentors on our draft EIS expressed concerns that the project could have negative impacts on tourism in the region. However, we could find no evidence to support that contention, and our analysis, provided in sections 4.8.1.4, 4.8.2.4, and 4.8.3.4, indicates that the project may have benefits for the local economy.

One of the main impacts on recreational users and tourists visiting parks and wildlife refuges along the lower Columbia River would be visual impacts associated with the passing of an LNG carrier in the waterway. As we discussed in section 4.7.1.5, visual impacts on recreational users and tourists should not be significant, as LNG carriers would normally transit in the waterway at speeds between 8 to 12 knots, and would only be visible to park and wildlife refuge visitors for a short period.

State and Local Parks

In Pacific County, Washington, Cape Disappointment State Park occupies about 1,882 acres on the Long Beach Peninsula between the Pacific Ocean and the Columbia River. In Clatsop County, Oregon, on the opposite side of the Columbia River at its mouth, is Fort Stevens State Park, covering about 3,700 acres.

In Warrenton, Oregon, the Zones of Concern along the waterway for LNG marine traffic would overlap the Waterfront Trail, Carruthers Park, and the Fisherman's Memorial and Lighthouse Park. In Astoria, Oregon, the Zones of Concern would overlap the Maritime Memorial Park, 6th Street Viewing Dock, 14th Street Riverpark, Riverwalk Trail, Victory Monument and Doughboy Statue, Astoria Column, Shively Park, the 4-H fairgrounds, Tapiola Park, Warren Field, Fred Lindstrom Memorial Park, and Yacht Club Park. In Wahkiakum County, Washington, the Zones of Concern would overlap Skamokawa Vista Park and Wahkiakum County Fairgrounds in Skamokawa, and Erickson Park and Strong Park in Cathlamet. State and local parks are described further in section 4.7.1.4. We believe that with the measures to be implemented by NorthernStar, and the conditions outlined in the Coast Guard's WSR, the likelihood for impacts on these parks is extremely remote.

National Parks, Trails, and Wildlife Refuges

The Zones of Concern along the waterway for LNG marine traffic would overlap two elements of the LCNHP (Cape Disappointment State Park and Fort Stevens State Park), the LCNHT, the Lower Columbia River Water Trail, and two national wildlife refuges, including the LCNWR and JBHNR. We address potential impacts on the LCNHP and LCNHT in section 4.9, and further discuss the national wildlife refuges in section 4.7.1.4. We believe that with the safety and security measures and conditions outlined in the Coast Guard's WSR, there would be little possibility of a spill of LNG from a carrier in transit to the terminal, and that the potential for adverse impacts on national wildlife refuges within the Zones of Concern along the waterway is extremely remote.

Cruise Ships

During scoping, comments were received regarding potential project-related impacts on large, ocean-going cruise ships that use the navigation channel of the Columbia River to reach Astoria. The Port of Astoria has been visited by cruise ships since 1996, and has invested more than \$10 million in improvements at Pier No. 1 to accommodate these vessels (Port of Astoria, 2006b). Eighteen cruises were scheduled to call on the Port during 2007 between April and November. Nineteen cruise ships are scheduled to make Astoria a port-of-call in 2008. The Coast Guard also recognized this issue, and its WSR contains the following conditions:

- when any cruise ship is moored at Astoria, LNG carriers would be restricted to transiting in good visibility (6 miles or more);
- any cruise ship at Astoria would require separate waterfront security when an LNG carrier is in transit in the vicinity; and
- a cruise ship and an LNG carrier would not be placed in a meeting situation.

We believe that with implementation of the conditions of the WSR, the potential for LNG marine traffic in the waterway to adversely affect cruise ships traveling to or docking at Astoria is extremely remote.

We received comments on the draft EIS regarding potential impacts on cruise ships that travel between Astoria and Portland. No large ocean-going cruise ships (i.e., the type of cruise ship referred to in the WSR) travel beyond the Port of Astoria to Portland. Several smaller river cruise vessels travel between Portland and Astoria that could be affected by passage of the LNG carriers associated with the proposed project. However, we expect that impacts on these smaller vessels would be similar to the impacts on other recreational river users as discussed below.

Recreational Fishing

The ODFW estimated that in 2005, anglers from Washington and Oregon combined to total more than 400,000 fishing trips along the lower Columbia River between Bonneville Dam and Buoy 10 (Watts and Takata, 2006). According to NorthernStar's *River User Impact Analysis*, about 46,000 recreational fishing boats go out on the Columbia River estuary between February and October, based on per-day use data from 2004.

We do not believe that the proposed project would have significant impacts on recreational fishing boats on the lower Columbia River. As discussed in sections 4.7.1.4 and 4.8.1.7, fishing boats are used to dealing with commercial ship traffic, and would merely move out of the way of LNG carriers

passing by in the waterway. Nor would the safety and security zones imposed by the Coast Guard around LNG carriers in the waterway or at dock at the terminal limit access to fishing grounds.

Non-Fishing Recreational River Users

Non-fishing recreational river users include power boaters, sailboaters, charter boat services, river cruise services, jet-skiers, water-skiers, windsurfers, kite surfers, kayakers, and canoers. Non-motorized water craft may be using the Lower Columbia River Water Trail for daily excursions. Recreational river users can access the lower Columbia River via boat ramps at Cape Disappointment State Park, Chinook County Park, Knappton, Oneida, Skamokawa Vista Park, East Sunny Sands, County Line Park, and Willow Grove Park in Washington, and at Youngs Bay Marine Park, Netul Landing, John Day Park, Knappa Docks, Aldrich Point, Westport, Jones Beach, Beaver Boat Ramp and Park, and Dibblee Point Beach in Oregon. There are marinas located in Ilwaco and Cathlamet, Washington; and at Hammond, Warrenton, and Astoria in Oregon. In addition, personal watercraft rentals are available in Warrenton, Oregon, and kayak rentals are available in Cathlamet and Skamokawa, Washington, and Warrenton, Oregon. Recreational river use is discussed in more detail in section 4.7.1.4.

The moving safety and security zone imposed by the Coast Guard around LNG carriers in transit up the waterway to the terminal may have temporary impacts on recreational river users. During the passage of the LNG carrier, other river users would have to briefly move to other portions of the Columbia River outside of the safety and security zone. Windsurfers, jet-skiers, kayakers, and canoers tend to use shallow waters near shore, and outside of the navigation channel. Some small recreational craft may be affected by wakes from LNG carriers. However, current recreational river users already have to contend with large commercial vessels and their wakes. Any inconveniences caused by the passage of an LNG carrier would be short term, since those vessels would travel at speeds between 8 and 12 knots.

4.8.1.9 Environmental Justice

Executive Order 12898 on Environmental Justice requires that each federal agency address disproportionately high and adverse health or environmental effects of its programs, policies, and activities on minority populations and low-income populations. As part of the preparation of this EIS, the NEPA review process must provide opportunities for effective community participation and involve consultation with affected communities. If the proposed action would result in significant adverse effects to minority or low-income populations or Native American tribes, the NEPA analysis should address those impacts as part of the alternatives analysis and identify appropriate mitigation measures to address the effects.

Tables 4.8.1-6 and 4.8.1-7 describe the ethnic and racial composition and income distribution of the communities occurring within the Zones of Concern associated with LNG carriers. Navy Heights, a suburb of Astoria, is the only community with a significantly higher percentage of people below poverty within the Zones of Concern along the waterway for LNG marine traffic. There are no predominantly minority communities within the Zones of Concern along the waterway for LNG marine traffic and the population of Native Americans is less than 2 percent of the total population. About 93 percent of the population of Warrenton is white non-Hispanic. Approximately 14.2 percent live below federal standards defining poverty. About 91 percent of the population of Astoria is white non-Hispanic. About 16 percent live below the poverty line. A little more than 94 percent of the population of Cathlamet is white non-Hispanic. About 15 percent are considered impoverished. Clatsop County in 2006 had an unemployment rate of about 5.7 percent (Bureau of Economic Analysis (BEA), 2007). In Pacific County in 2005, about 2,300 people per month received either state or federal non-medical assistance. In Wahkiakum County in 2005, about 320 people per month received either state or federal non-medical assistance. Therefore, neither low-income nor minority groups would be disproportionately affected by LNG carrier transit.

4.8.2 LNG Terminal

4.8.2.1 Population

Population statistics for areas where socioeconomic effects would occur due to construction of the LNG terminal area are provided in table 4.8.2-1. These areas vary widely in their population totals and densities. Both Clatsop and Columbia Counties in Oregon have population densities higher than the average for the State of Oregon (44.0, 71.5, and 36.6 persons per square mile, respectively). The highest population density in the area occurs within the Portland MSA, which has a population density of 381.5 persons per square mile. The least densely populated county affected by the project is Wahkiakum County, with an average density of 14.2 persons per square mile. Populations in the four-county area range from 3,755 persons in Wahkiakum County to 96,189 persons in Cowlitz County (U.S. Census Bureau, 2004).

TABLE 4.8.2-1					
Existing Population in the Areas Where Socioeconomic Effects Would Occur as a Result of Construction and Operation of the Bradwood Landing LNG Terminal and Natural Gas Sendout Pipeline					
State/County/ MSA or Community	Population			Population Density ^a

U.S. Census Bureau, 2006.					

No appreciable changes to the local population distribution or number are expected to occur as a result of the proposed LNG terminal. The total population change would equal the total number of non-local construction workers, plus any family members accompanying them. NorthernStar anticipates that the majority of the labor force for construction of the LNG terminal would come from Clatsop, Columbia, Wahkiakum, or Cowlitz Counties (i.e., four-county area),²¹ or from the Portland MSA (Columbia Pacific Building Trades Council, 2005). Ten or fewer specialty workers or managers may temporarily relocate to the area during construction of the proposed LNG terminal. Based on the average family size within the areas affected of 3.1 persons (U.S. Census Bureau, 2000), if 10 workers relocate to the study area, the population would increase by approximately 30 people. This potential population increase would be easily absorbed by the affected areas. NorthernStar has indicated that it is committed to hiring and training local residents during operation of the project. Based on commuting patterns at the nearby Wauna Mill (Georgia-Pacific, 2004), almost all of the permanent employees of the LNG terminal would likely reside within a radius of about 80 miles. Therefore, operation of the LNG terminal would not directly result in a noticeable population increase in the local community.

4.8.2.2 Housing

Housing statistics for the areas where socioeconomic effects would occur due to construction of the proposed LNG terminal are presented in table 4.8.2-2. Vacancy rates in the vicinity of the project range from 5.7 percent in the Portland MSA to 25.3 percent in Clatsop County. Temporary housing availability varies seasonally and ranges from bed and breakfasts to hotels and motels, and from studio apartments to four-bedroom homes. Based on information from local hotels, the tourist season in this region runs from June through September. During this season, vacancy rates average 15 percent. During the off-season, vacancy rates are approximately 45 percent (Astoria-Warrenton Area Chamber of Commerce, 2005). In addition, temporary housing is available in campgrounds and recreational vehicle (RV) parks, which provide over 2,000 individual sites in the four-county area.

²¹ Pacific County is not expected to provide a source of workers for either construction or operation of the LNG terminal.

State/County/MSA	Total Housing Units	Total Vacant Housing Units	Vacancy Rate (percent)	Median Gross Monthly Rent
Oregon	1,452,709	118,986	8.2	\$620
Clatsop County	19,685	4,982	25.3	\$543
Columbia County ^a	17,572	1,197	6.8	\$581
Portland MSA	786,300	44,524	5.7	\$672
Washington	2,451,075	179,677	7.3	\$663
Wahkiakum County	1,792	239	13.3	\$519
Cowlitz County	38,624	2,774	7.2	\$518
Puget Island	404	72	17.8	\$783

^a Housing statistics from Columbia County are also included in the Portland MSA.
Source: U.S. Census Bureau, 2000.

Construction and operation of the LNG terminal are not expected to affect the availability of housing in the study area. As discussed in section 4.8.2.1, NorthernStar would employ local workers who would reside within commuting distance of the project. Approximately 75 percent of the construction workforce for the LNG terminal would commute daily from the Portland MSA. It is assumed that commuting workers would not require temporary housing. This use of local workers depends primarily on union agreements, the contractor hired for the project, and the methods the contractor uses to hire subcontractors (Columbia Pacific Building Trades Council, 2005). NorthernStar estimates no money would be spent on temporary housing for the commuting construction workers.

During construction of the proposed LNG terminal, 10 or fewer workers may be hired from outside the area. Based on the average family size of 3.1 persons described in section 4.8.2.1, we estimate that as many as 30 people may move into the area as a result of construction of the LNG terminal. This relatively small number of non-local people requiring housing would not adversely affect the regional housing market.

4.8.2.3 Property Values

Comments were received during scoping regarding the potential effect of the project on property values. Property values on Puget Island are among the highest in Wahkiakum County due to the waterfront access and views. Factual projections of future land values on Puget Island would not be possible until the LNG terminal is in place and property sales data begin to accumulate (Wahkiakum County Commission, 2005).

There are few empirical studies on the impact of industrial facilities on nearby property values. A 1993 study conducted by the Argonne National Laboratory examined the economic impacts of the presence of “noxious” facilities on local wages and property values. Eight types of facilities were studied: nuclear power plants; coal-, gas-, or oil-fired power plants; military chemical weapons sites; hazardous waste sites; refineries; chemical weapon storage sites; former chemical weapon storage sites that are now contaminated; and LNG storage plants. The study examined the effects of 262 facilities on standardized 1,000-square-mile areas across the United States. Eleven of these were LNG facilities. The results of the study concluded that the presence of five of the eight types of “noxious” facilities have a significantly negative effect on property values and a positive effect on wages. However, the study concluded that the presence of an LNG facility did not have a significant positive or negative effect on either wages or property values (Clark and Nieves, 1993).

A 2006 study examined local county assessment records for neighborhoods surrounding existing LNG “peak storage” facilities in Newport and Portland, Oregon. The study found that property values around the Newport LNG plant are not depressed, and within 0.5 mile of the facility are about 25 homes with above average market value. Around the Portland LNG plant are many other industrial or commercial properties, and new businesses continue to move into the area. The study concluded that there is no evidence to support the concern that the presence of an LNG storage facility would reduce nearby property values (ECONorthwest, 2006).

4.8.2.4 Economy and Employment

Existing economic conditions in the areas where socioeconomic effects would occur due to construction of the LNG terminal are provided in table 4.8.2-3. Within these areas, average per capita income was slightly lower than the averages for Oregon and Washington (\$20,940 and \$22,973, respectively). In contrast, the per capita income for the Portland MSA was \$23,321, which was slightly higher than average for the State of Oregon. In 2004, the unemployment rates for counties within the study area were similar to or slightly higher than state averages, ranging from 5.0 percent within Clatsop County to 8.0 percent in Puget Island.

TABLE 4.8.2-3				
Existing Economic Conditions in the Areas Where Socioeconomic Effects Would Occur as a Result of Construction and Operation of the Bradwood Landing LNG Terminal and Natural Gas Sendout Pipeline				
State/County/MSA	Per Capita Income (2000)	Civilian Labor Force (2000)	Unemployment Rate (percent) (2006)	Top Industries by Employment (2000)
Oregon	\$20,940	1,740,298	5.4	Education, Health and Social Services (19.3%) Manufacturing (14.4%)
Clatsop County	\$19,515	17,656	5.0	Education, Health and Social Services (19.2%) Arts, Entertainment, Recreation, Accommodation, and Food Services (15.7%)
Columbia County	\$20,078	21,379	5.8	Manufacturing (22.1%)
Portland MSA	\$23,321	1,089,000 ^a	5.1	Education, Health and Social Services (15.8%) Education, Health and Social Services (21.7%) Trade, Transportation, and Utilities (20.2%)
Washington	\$22,973	2,979,824	5.0	Education, Health and Social Services (19.4%) Manufacturing (12.5%)
Wahkiakum County	\$19,063	1,691	6.5	Education, Health and Social Services (24.6%) Agriculture, Forestry, Fishing and Hunting, and Mining (14.6%)
Puget Island	\$22,444	374	8.0	Education, Health and Social Services (29.1%) Manufacturing (12.2%)
^a U.S. Department of Labor, Bureau of Labor Statistics, 2005. Sources: U.S. Department of Agriculture, Economic Research Service, 2004. U.S. Census Bureau, 2000. U.S. Department of Labor, Bureau of Labor Statistics, 2006.				

As discussed in section 4.8.2.1, most of the labor force for construction of the LNG terminal is expected to come from the four-county area or from the Portland MSA. NorthernStar anticipates that 10 or fewer specialty workers and managers may be hired from outside the study area for construction of the LNG terminal. Tables 4.8.2-4 and 4.8.2-5 list the estimated construction workforce for the LNG terminal and the counties of residence NorthernStar anticipates the workers to commute from, respectively.

TABLE 4.8.2-4		
Estimated Construction Workforce for the LNG Terminal		
Timeframe	Average Number of Workers per Month	Percent of Total Construction Workforce
Year 1	220	22.2%
Year 2	470	47.3%
Year 3	303	30.5%
Average Workforce	331	--
Peak Construction (months 20 - 26)	506	--

TABLE 4.8.2-5			
Sources of Construction Workers for the LNG Terminal			
Location	Average Number of Workers Commuting	Percent of Workers Commuting	Number of Workers Commuting During Peak Construction
Clatsop County	50	15	76
Portland MSA	248	75	380
Columbia County ^a	16	5	25
Washington	33	10	50
Total ^b	331	100	506
<p>Note: Sum of addends may not be the same as the total due to rounding.</p> <p>^a Construction workers from Columbia County are also included in the Portland MSA; therefore, they are not included in the project total.</p> <p>^b LNG terminal total does not include up to 10 specialty workers and managers that may be hired from outside the study area.</p> <p>Source: Columbia Pacific Building Trades Council, 2005.</p>			

NorthernStar estimates that an average of 331 workers would be employed during the 3-year LNG terminal construction period, with a peak workforce of 506 occurring between months 20 and 26. Approximately 75 percent of the construction workforce is expected to commute from the Portland MSA (5 percent of this total would reside in Columbia County). The remaining 25 percent is expected to commute from Clatsop County (15 percent) and Wahkiakum and Cowlitz Counties (10 percent). Workers are expected to commute to the project site daily, and would generally work four 10-hour days per week. The commute between Portland and the LNG terminal is about 80 miles. While this appears to be a long daily commute, sources indicate that compensation for commuting creates an incentive for workers to commute, rather than temporarily relocate (Columbia Pacific Building Trades Council, 2005).

Construction expenditures by NorthernStar would increase economic activity within the counties affected by the project, which would have a multiplier effect on the local economy. The notion of a multiplier effect rests upon the difference between the initial effect of a change, the actual expenditure by NorthernStar, and the total effects of that change. The total increase is calculated using the direct, indirect, and induced effects of the initial change. These effects are best described as:

- Direct Effects. The changes associated with the immediate change in final demand, such as the hiring of local construction workers and purchases of goods and services from local businesses.
- Indirect Effects. The production changes in backward-linked industries caused by the changing needs of the directly affected industries. For example, the additional purchases to address the increased demands for goods and services would be considered indirect effects.

- Induced Effects. The changes in household spending patterns caused by the changes in household income generated from the direct and indirect effects are induced effects.

To calculate this additional impact on the local economy, a data and software program called IMPLAN (Impact analysis for PLANning) was used to generate multipliers for output (total impact), employee compensation (payroll (i.e., wages and benefits)), and employment. IMPLAN uses an input-output model that examines the relationships between and among industries and assigns values to these based on national, state, and regional data. The most recent data available for this model is from 2004. IMPLAN was originally developed by the FS, in cooperation with the FEMA and the BLM (Olson and Lindall, 1999).

IMPLAN allows the user to build economic models to estimate the impacts of economic changes. Database sources for IMPLAN data are primarily government sources. IMPLAN accounts closely follow the accounting conventions used in the “Input-Output Study of the U.S. Economy” by the BEA) and the rectangular format recommended by the United Nations. For data analysis and manipulation, IMPLAN uses a sectoring scheme that has 509 sectors. This sectoring scheme is based on the North American Industry Classification System (NAICS) and closely follows the 1997 BEA Benchmark Study for the United States. The IMPLAN sector used for the construction portion of this analysis was sector 41 - Other New Construction. This IMPLAN sector includes those activities associated with the main category of Heavy and Civil Engineering Construction (NAICS 237). For the operation portion IMPLAN sector 31 - Natural Gas Distribution was used. This correlates to NAICS sector 2212, which is also Natural Gas Distribution.

IMPLAN analysis focuses on two impacts: economic impact and employment impact. Also included is a discussion of increased payroll, which is part of the total economic impact. Economic impact is calculated for amounts spent directly in the four-county study area (Clatsop and Columbia Counties, Oregon and Wahkiakum and Cowlitz Counties, Washington).²² Different percentages of the payroll and construction costs are expected to remain in the four-county area. For these reasons, payroll and construction costs are separated for calculation purposes. Expenditures for each category are estimated (direct impact) and the indirect and induced impacts are then calculated. Table 4.8.2-6 shows the estimated economic impact of construction of the LNG terminal.

TABLE 4.8.2-6					
Economic Impacts of Construction of the LNG Terminal					
Project Component/Impact	Project Total	Four-county Area Impact (30 percent of estimated workforce)			
		Direct Impacts	Output Multiplier ^a (approximate)	Indirect and Induced Effect	Total Four-county Impact
Economic Impact ^b	\$600,000,000	\$77,591,806	1.87	\$68,453,351 ^c	\$146,045,157 ^c
Payroll ^d	\$87,959,035	\$26,387,710	1.97	\$25,596,079 ^c	\$51,983,789 ^c
Employment ^e	331	99	1.83	82	181
^a	IMPLAN calculates the results of the multipliers based on a per million dollar change in final demand (total direct expenditures).				
^b	Payroll and expenditures over 3-year LNG terminal construction period.				
^c	Includes dollars spent by workers in the study area during construction.				
^d	Payroll over 3-year LNG terminal construction period.				
^e	Based on monthly averages.				

²² Although Pacific County could be affected during operation of the LNG terminal because it is located along the waterway, it is not expected to provide a source of workers for either construction or operation of the project and, therefore, was not included in the economic analysis.

Project-related employment and expenditures would have a direct and positive effect on employment and economy within the study area. Total construction costs for the LNG terminal are estimated to be \$600 million. NorthernStar estimates that total payroll (which includes both wages and benefits) for the construction of the LNG terminal would be \$88 million. Approximately \$26.4 million of this would go toward payroll for construction workers from the four-county area with payroll averaging \$8.8 million per year for the 3-year construction period. Payroll estimates for construction of the LNG terminal were based on published prevailing rates and do not reflect any negotiated rates that may apply. NorthernStar anticipates that approximately 30 percent of the workers employed for construction of the LNG terminal would commute from the four-county area and would spend their pay locally. Within the four-county area, NorthernStar estimates that total direct expenditures on goods, equipment, and services during construction of the LNG terminal would be \$77.6 million.

During construction of the proposed LNG terminal, construction work would increase the second year and decrease during the third year of construction. Direct increases in local payroll during construction of the LNG terminal would be approximately \$5.9 million during year 1, \$12.5 million during year 2, and \$8.1 million during year 3. Of this, 50 percent of these increases would go to workers in Clatsop County, 16 percent to Columbia County, and 34 percent to the Washington counties.

Operation of the Bradwood Landing Project would result in about 65 new permanent positions. In addition, tug operations necessary to support the LNG terminal would require about 40 employees. NorthernStar plans to hire and train local residents for operation of the facility. Based on the commuting patterns at Wauna Mill, which is located less than 3 miles south-southeast of the proposed LNG terminal, NorthernStar estimates that approximately 27 workers would come from Columbia County, 23 from Clatsop County, 12 from Cowlitz County, 2 from Wahkiakum County, and 1 from Clark or Pacific County. Table 4.8.2-7 shows the estimated annual impacts of operation for the project.

TABLE 4.8.2-7					
Annual Economic Impacts of Operation of the LNG Terminal					
Impact	Project Total	Four-county Area Impact (98 percent of estimated workforce)			
		Direct Impacts	Output Multiplier ^a (approximate)	Indirect and Induced Effect	Total Four-county Impact
Economic Impact (first year) (Includes payroll and expenditures)	\$30,000,000	\$15,900,000	1.28	\$4,452,000	\$20,352,000
Annual Payroll	\$3,900,000	\$3,900,000	1.61	\$2,379,000	\$6,279,000
Employment	65	65	2.74	113 ^b	178
^a IMPLAN calculates the results of the multipliers based on per million dollar change in final demand (total direct expenditures).					
^b Does not include the approximately 40 persons required to operate tugs.					

The estimated average salary for workers at the facility would be \$60,000 per year. Including the direct and indirect impacts, based on the distribution of workers discussed above, there would be an estimated annual income of about \$145,000 for workers from Wahkiakum County, \$919,000 for workers from Cowlitz County, \$1.7 million for workers from Clatsop County, and \$2 million for workers in Columbia County. Most indirect and induced employment impacts would be full- and part-time employment in the service sector.

As a portion of the operations cost, NorthernStar would lease three tugs from businesses in the four-county area at an annual cost of \$4 million. The IMPLAN multipliers used to calculate the impact of the LNG terminal are for the distribution of natural gas and do not capture the unique nature of an LNG

facility such as the impact of the tugs on the local economy. Therefore, the additional impact is not fully captured in the calculated impacts of operation. For example, a portion of the \$4 million would be spent by the local companies to hire approximately 40 crew and support personnel to operate the tugs. This additional local impact on employment is not reflected in the IMPLAN payroll or employment numbers, and would most likely benefit Wahkiakum County since tugs are expected to be stationed across from the LNG terminal in Wahkiakum County.

4.8.2.5 Tax Revenues

Construction and operation of the Bradwood Landing LNG terminal would have beneficial impacts on property and corporate tax revenue in Clatsop County. The LNG terminal would significantly strengthen the property tax base for the local school district and other government services in the local community. Property tax, calculated on the assessed value of the property, would be collected by Clatsop County and distributed to special districts in the county. Any additional public needs in the surrounding counties would need to be covered through other revenue sources including grants. The Clatsop County Assessment and Taxation Department and the Oregon Department of Revenue indicated that the property would most likely be assessed at 100 percent of its market value, which is estimated at \$600 million upon project completion (Solheim, 2005; Blacklock, 2005). It is anticipated that the LNG terminal would be located in Tax Code Districts 04-01 and 04-03. Based on the 2006-2007 tax rates for Tax Codes 04-01 and 04-03, NorthernStar would pay approximately \$7.8 million in annual property taxes upon completion of the LNG terminal. Of this amount, \$4.2 million would go to the Knappa School District. Based on current assessments, the total for all property tax revenue expected in Clatsop County in 2006-2007 is \$6,543,300 (Clatsop County, 2007). Based on the current tax rates, property tax revenue for Clatsop County and special districts would increase by 119.2 percent upon completion of the LNG terminal.

The increased property tax base upon construction of the LNG terminal could place the Knappa School District in the situation of having tax revenues that would improve educational opportunities. In general, any shortfall in local tax revenues is funded by state government. The Oregon Department of Revenue requests all school districts to tax at their maximum rate. If they do not, they are penalized by lower funding levels from the state. Any excess beyond requirements can be kept by the school district, which would be the case for the Knappa School District.

Of importance to Knappa Schools is the effect on bond levy rates. Assuming a one-time increase in the Knappa School District's assessed property value when the LNG terminal comes on line, residents of the district may see a decrease in the bond levy rate from 2.45 to 0.61 by 2015 per \$1,000 of assessed property value, according to estimates of the Investment Banker for the school district. The total tax rate for the Knappa School District would then be 5.2167 instead of 7.0567. This would result in total property taxes paid by NorthernStar of \$6.0 million, \$3.1 million of which would be collected due to the school district tax rate.

For the initial years of its operation, through approximately 2010, the project would have little or no state income tax liability because deductions for depreciation and amortization of investments and other expenditures are expected to exceed initial gross income. Beginning in 2011, NorthernStar projects that it would have annual taxable income from the operations in Oregon of about \$75 million to \$100 million. Based on current tax rates for corporations doing business in Oregon (6.6 percent), NorthernStar would have annual Oregon tax liability of about \$5 million to \$8 million beginning in 2011.

4.8.2.6 Local Infrastructure and Public Services

A range of public services are provided in the cities and counties in the vicinity of the proposed LNG terminal. Public services in the area include law enforcement and emergency services, schools, and utilities.

Table 4.8.1-4 provides an overview of existing hospitals, ambulance services, fire departments and law enforcement in the areas where socioeconomic effects would occur due to the proposed project. Two hospitals are located in Clatsop County (Columbia Memorial Hospital and Providence Seaside), with a combined total of 105 beds. St. John's Hospital serves Cowlitz County, and residents of Columbia County are served by an outpatient clinic in St. Helens that is open Monday through Friday (Legacy Health Systems, 2006). Wahkiakum County owns the Wahkiakum Family Practice Clinic, which provides family practice care (Wahkiakum County Commission, 2005).

Fire protection at the LNG terminal would be provided by the Westport Wauna Fire District, which is located about 6 miles southeast of the site, and by the Knappa-Svensen-Burnside Rural Fire Protection District (RFPD), located about 10 miles west of the site. The ODF is an oversight agency for Rural Fire Protection Districts in Oregon, and is a responder to forest fires on private and state owned lands. The closest ODF fire fighting unit is located in Clatskanie, Oregon. Wahkiakum County does not currently have a staffed fire department; however, the county does have a volunteer fire protection service.

The Clatsop County Sheriff's Office would be the primary law enforcement agency responsible for the LNG terminal. In 2005, the Clatsop County Sheriff's Office employed 60 officers and had 29 patrol vehicles. Upon completion of construction, NorthernStar would also employ its own security force, thereby reducing need for local public services.

We received comments during the scoping period regarding the current capacity of local public services to respond to an incident or fire at the LNG terminal. NorthernStar has indicated that trained personnel and fire fighting equipment would be maintained at the LNG terminal in the event of an emergency. The Coast Guard has determined that significant gaps exist in fire fighting capability for both shore and water side fire fighting response. In addition, both Clatsop County and the City of Clatskanie have filed requests, through the ODE, that FERC take into account gaps in local services that would need to be filled in order to ensure public safety, and properly respond to an accident or fire at the LNG terminal.

NorthernStar filed its first draft ERP on March 24, 2008. The ERP includes a cost-sharing plan that outlines how NorthernStar would fill resource gaps and supplement the first-responder capabilities of the local communities near its proposed LNG terminal. The ERP is discussed in more detail in section 4.11.6.

A total of 94 schools are located within the areas where socioeconomic effects would occur due to construction of the LNG terminal, with a total enrollment of about 33,300 students (School Tree, 2007). As discussed above, the LNG terminal would be located within the Knappa School District, which consists of one elementary school and one high school. Current enrollment in the Knappa School District is 603 students (School Tree, 2007). Because most workers would be expected to commute from their current residences, only a nominal increase in enrollment at the local public schools would occur as a result of the relocation of construction or operation workers and their families.

No utilities currently serve the site of the LNG terminal and none are available in the immediate vicinity. As a result, NorthernStar would construct an electrical substation, an on-site wastewater

treatment system, and a fire protection system. Power would be supplied by a new 115 kV power line connecting the Bradwood Landing LNG terminal and the existing PacifiCorp electric system. The use and purchase of power from PacifiCorp would not reduce supplies to other users in the local area. The wastewater treatment system is discussed in detail in section 4.3.1.3. The fire suppression system is discussed in section 2.8.1.3. Because the LNG terminal would have its own wastewater treatment, the project would not have an effect on any existing public wastewater treatment facilities. In addition water would be provided by an on-site well and the Columbia River, so no municipal water supply would be necessary.

Fire and other emergencies at the proposed LNG terminal could require the services of local fire departments and emergency response units, as discussed above. Other than the services of local first responders, we do not believe that construction and operation of the LNG terminal would have any other adverse impacts on local infrastructure and public services. The vast majority of the workers at the terminal would commute from within a radius of about 80 miles. As current residents of the region, these workers are already part of the local tax base, and would be accounted for in the provision of local infrastructure and public services by nearby cities and counties. Because few non-local workers would relocate to the area for this project, only a small number of new students would need to be absorbed into the local school district.

4.8.2.7 Transportation and Traffic

Road Traffic

Construction of the Bradwood Landing LNG terminal could affect transportation and traffic in the project area by increasing the number of vehicle trips per day on area roads as a result of commuting and construction vehicle traffic. Construction workers traveling to and from the LNG terminal site could generate up to 1,500 vehicle trips per day (NorthernStar anticipates a peak workforce of up to 506 workers when construction of the LNG terminal is underway). Workers and construction traffic would largely access the LNG terminal via Oregon State Route 30, Clifton Road, and Bradwood Road. It is also possible that workers commuting from Cowlitz and Wahkiakum Counties could travel on Washington State Route 4 and take the Puget Island Ferry to reach the proposed LNG terminal.

Highway 30 is a two-lane, east-west highway that connects Astoria to Portland. Traffic counts completed by the ODOT in 2004 for Highway 30 near the proposed Bradwood Landing LNG terminal site were 6,600 average daily trips; however, traffic levels are higher during the summer tourist season (ODOT, 2004). An independent traffic impact analysis conducted in May 2006 by CTS Engineers, in consultation with the ODOT and Clatsop County, found 6,200 average daily trips over 2 days on Highway 30 at Clifton Road. The traffic count data revealed that the morning peak hour occurs between 6:00 and 7:00 AM and the evening peak hour occurs between 3:00 and 4:00 PM. Truck traffic (vehicles with three or more axles) accounted for about 19 percent of both daily and peak hour traffic volumes through the intersection (CTS Engineers, 2006).

Most of the construction workers would park in the construction parking area located southeast of the Taylorville interchange at Highway 30. From this parking area, the workers would be bussed to the LNG terminal site to the maximum extent possible. A smaller parking area would be provided at the proposed LNG terminal site.

During construction of the Bradwood Landing Project, NorthernStar anticipates an average of 30 trucks per day delivering construction equipment and supplies to the LNG terminal and along the pipeline route. However, during peak construction, up to about 80 trucks would make deliveries to the LNG terminal and along the proposed pipeline route. The increased traffic levels associated with construction

of the LNG terminal would be temporary and limited to the period of construction (about 3 years). To minimize additional impacts on traffic, NorthernStar would minimize trips to and from Bradwood, and would develop a traffic management plan. Some of the traffic minimization techniques proposed by NorthernStar include:

- Use of the railroad to bring in heavy loads of material. These materials include plate steel for the tanks, rebar, concrete, piping, structure steel, pilings, etc.
- An on-site rock quarry may be used for the production of concrete aggregate.
- Construction workers would park their vehicles at the construction parking area on Highway 30. Buses would then be used to move workers to the job site. In addition, NorthernStar has committed to establishing policies to encourage workers to use carpooling and vanpooling to further reduce the potential for traffic impacts.
- Delivery of materials by truck would be scheduled so as to not coincide with movement of the buses bringing construction workers to and from the site.

Following construction, the LNG terminal would operate 24 hours per day, 7 days per week. Peak site activity would vary throughout the day and week depending primarily on the schedule of LNG carrier arrivals. As discussed in section 4.8.2.4, the equivalent of 50 full-time staff would be employed to operate the facility and an additional 15 employees would provide security. The anticipated traffic volume resulting from operation of the LNG terminal, even during peak operation periods, would not significantly increase the existing traffic volumes on local area roadways. Traffic resulting from operation of the LNG terminal is expected to be fewer than 125 vehicle trips per day.

Clifton Road is an approximately 20-foot-wide paved road currently maintained by Clatsop County that intersects with Highway 30. The traffic impact analysis found that, currently, Clifton Road experiences fewer than 50 vehicles per day in this area.

Clifton Road is a two-lane road that is cut into the side of a slope for the most part, and in several places is too narrow for two large trucks to pass safely at normal speed. As the road travels north from Highway 30 and the parking area to Bradwood it loses several hundred feet of elevation. Clifton Road follows Hunt Creek towards Bradwood. To the west of the road the slope rises; to the east of the road the slope falls towards the creek. During the planning process for the Bradwood Landing Project, NorthernStar consulted with the ODOT and Clatsop County regarding modifications to Clifton Road to reduce impacts of traffic associated with the project. As a result of those consultations, prior to construction of the LNG terminal, Clifton Road would be widened to 28 feet, resulting in two 12-foot travel lanes with a 2-foot shoulder on each side of the road. An east-bound turning lane and a west-bound deceleration lane would be installed on Highway 30 at the intersection of Clifton Road. On April 14, 2008, the Clatsop County Board of Commissioners voted to approve variances for NorthernStar's use of Clifton Road (The Daily Astorian, 2008).

About 2.4 miles from Highway 30, Clifton Road intersects with Bradwood Road. After this intersection, Clifton Road continues northwest along the Columbia River to the Town of Clifton. Bradwood Road is currently a 1,150-foot-long gravel road that connects Clifton Road and the LNG terminal site. NorthernStar would widen Bradwood Road to 24 feet by clearing and grading the area directly adjacent to the existing road. Following clearing and grading, the road would be paved in order to accommodate the large trucks required for the project. Impacts on traffic are not anticipated as a result of planned improvements to or increased use of Bradwood Road because it is not currently used by the public.

The existing Hunt Creek Bridge, located on Bradwood Road, is not adequate to withstand the anticipated vehicle loads associated with construction of the project. Therefore, NorthernStar would replace the bridge with a new one built of four 75-foot-long, 3-foot-high, pre-cast concrete deck bulb T-girders. These would be supported on concrete-filled steel piles that would be placed above the MHHW elevation. See section 2.4.1.1 for additional details regarding the Hunt Creek Bridge replacement.

Ship Traffic

Many commercial and recreational vessels utilize the Columbia River. Annual ship traffic at the mouth of the Columbia River in recent years has been roughly 2,000 round-trips.

Dredging of the turning basin may interfere with commercial and recreational vessel use of the Columbia River. Because the temporary mooring of the dredge barges would occupy a relatively large portion of the channel throughout dredging operations, this equipment might present an obstruction to navigation. Transit and mooring of the dredge barges would be required to comply with applicable COE and Coast Guard regulations. In addition, dredging would only occur between November and January, when river use is lowest. Barges would not be used to bring supplies to the LNG terminal during construction.

Operation of the LNG terminal itself would not affect commercial or recreational uses of the Columbia River. None of the structures to be constructed as part of the ship berth would be located within the navigation channel. Navigational marking and operation of the structures would be conducted in accordance with applicable Coast Guard and COE regulations. Impacts on ship traffic associated with the arrival and departure of LNG carriers during operation of the proposed LNG terminal were previously discussed in section 4.8.1.7.

Train Traffic

One set of railroad tracks currently passes through the proposed Bradwood Landing LNG terminal. The PWRR historically connected Portland with Astoria. Although PWRR owns the tracks and appurtenances associated with the railroad, the underlying right-of-way and railroad bridges are owned by the ODOT. It may be possible for NorthernStar to use the rail line for delivery of materials by train during project construction.

Originally known as the Astoria and Columbia River Railroad and completed in 1898, the PWRR is discussed as an historic resource in section 4.9. Passenger train service through the terminal site was abandoned in 1952 due to low ridership.²³ Anecdotal information collected by NorthernStar indicates that, with the exception of the brief period described below, a train has not run through the terminal site since at least 1987. In fact, soil covered the railroad tracks for at least 12 years prior to the clearing of the tracks to allow the Lewis & Clark Explorer Train (LCET) to temporarily operate from 2003 to 2005. From 2003 to 2005, during the bicentennial celebration of the Lewis and Clark expedition, the LCET provided summer-only passenger train service between Portland and Astoria. The LCET was heavily subsidized, and the service was terminated in 2005 when the subsidy ended.

Since the termination of the LCET service, a train has not operated through the Bradwood Landing terminal site. There is currently no traffic on the railroad, and the PWRR has no plans to operate trains west of Wauna. In 2006, a segment of tracks were washed out west of Bradwood, approximately half-way to Astoria. The tracks have not yet been repaired, although the PWRR is in discussions with the local diking districts to repair the dikes and restore the tracks.

²³ <http://www.nationalcorridors.org/df/df06022003.shtml>

NorthernStar proposes to modify the railroad right-of-way owned by the ODOT. The modification would consist of rerouting the segment of the railroad tracks that runs through the proposed LNG terminal property up to 250 feet south of its present location.

In November 2005, NorthernStar, PWRR, and the ODOT agreed to enter into a Railroad Relocation Agreement. To date, the alignment of the planned relocation has been reviewed and accepted by the railroad management as consistent with their future plans. However, the agreement has not yet been finalized. Therefore, **we recommend that:**

- **NorthernStar should file a copy of the final Railroad Relocation Agreement with the Secretary prior to LNG terminal construction.**

As discussed in section 4.11.4, the proposed relocation of rail track routing would be within the thermal exclusion zone for the LNG tank impoundment area. Therefore, in response to our recommendation in the draft EIS, NorthernStar provided procedures for coordinating with the railroad company to ensure safe rail transit through the Bradwood Landing LNG terminal property.²⁴

An upset condition could be an act of nature, such as an earthquake or severe storm; a fire at the terminal or surrounding site; or a hydrocarbon leak. Events that require an emergency response are not likely to occur, or would be very rare (with the exception of severe storms, which are still infrequent). Regardless of the unlikelihood of an upset condition at the facility, it is still necessary to have executable procedures in place for the notification of the railroad. These procedures would only be used if the PWRR resumes train service along the tracks through the proposed Bradwood Landing LNG terminal property.

Because only one set of railroad tracks runs through the Bradwood Landing property, the railroad may schedule future trains so that there is either an east bound train or a west bound train running at any one time. Railroads operate trains on a routine schedules. Therefore, if trains were to run through the LNG terminal property, NorthernStar would know the train schedule in advance, and be able to coordinate its response procedures with the PWRR.

The PWRR has a dispatch operator that is reachable by direct phone line 24 hours per day, 7 days per week. If there is an upset event at the terminal, NorthernStar would call the railroad dispatch operator, who would call the train engineer, and tell the engineer to stop the train short of the terminal until the all clear is given.

Non-Emergency Operational Upsets

In the event of non-emergency operational upsets, a notification shall be made to the PWRR providing the following information:

- Description of upset/activity: scheduled or unscheduled maintenance, equipment failure, etc.
- Location at facility of upset: wharf, control room building, etc.
- Anticipated duration: when will upset condition be remedied; when will routine operations commence?

²⁴ On October 15, 2007, NorthernStar filed its response to our recommended environmental condition 41 from the draft EIS. This document is available for viewing by the public through the FERC's internet webpage at www.ferc.gov using the elibrary link. Type in Docket no. CP06-365, and the appropriate date, and look up accession number 2007018-0212.

- Any safety issues: description of any issues that may result in an increase, or otherwise influence safety or railroad passage or track use.
- Change of status: any change to operational upset conditions or other information previously reported.

An initial notification to the PWRR would be made as part of the initial action to any facility emergency response. For non-emergency operational upset situations, NorthernStar would notify the PWRR dispatcher when conditions at the terminal return to normal and would include a final recommendation regarding the use of the railroad. The dispatcher would communicate the all clear to the train engineer.

Emergency Response Conditions

A number of emergency response events have specific response plans. These include:

- spill or release
- severe weather
- fire
- bomb threat
- earthquake
- terrorist incident
- LNG carrier response

In the event of an emergency response, an initial notification shall be made to the PWRR consisting of the following information:

- Description of upset/activity: LNG spill, fire, etc.
- Recommendation of immediate action by railroad: whether conditions and/or risks are such that a train should be stopped outside the terminal until the situation improves.

A follow-on notification shall be made providing the following clarifying information as it becomes available:

- Location at facility of emergency: wharf, control room building, etc.
- Anticipated duration of emergency: when will the emergency be remedied; when will terminal and/or Emergency Responders stand down from response operations?
- Any intermediate safety issues: description of any issues which may result in an increase, or otherwise influence safety, railroad passage, or track use; safety related information in addition to that provided in the initial notification.

Recovery actions from an emergency response condition depend on the nature, severity, and in some cases, the duration of the event. Emergency responses may be handled completely by Bradwood Landing terminal personnel or, for responses to events of significant magnitude, it may be appropriate to establish a Unified Command. In the case of a Unified Command structure for the response, the all clear communication to the PWRR dispatcher would be made jointly by the Unified Command and NorthernStar. The dispatcher would communicate the all clear to the train engineer.

4.8.2.8 Recreation and Tourism

Comments were received during scoping regarding the potential project-related impacts on local recreational activities and tourism. Developed recreational facilities near the LNG terminal include Erikson City Park, Strong Waterfront Park and Trail, Elochoman Slough Marina, and Skyline golf course in Cathlamet, about 2.5 miles to the north. Skamokawa Vista Park is located about 4.3 miles from the LNG terminal. We believe that because of this distance, these recreational facilities would not be adversely affected by the construction or operation of the LNG terminal. Recreational activities near the LNG terminal include use of the Columbia River by boaters, including users of the Lower Columbia River Water Trail, and use of public beaches along the river. These activities are discussed in detail in sections 4.7.1.4 and 4.7.2.6. The main impact the LNG terminal may have on recreational river users would be from dredging the maneuvering area adjacent to the navigation channel. Operation of the LNG terminal should not have any direct impacts on recreation, because this parcel is on privately owned land without public access. However, there could be indirect visual impacts on recreational users of the Columbia River, Clatsop State Forest, JHBNWR, the Elochoman Slough Marina, and Skamokawa Vista Park (see section 4.7.2.7).

There are no easily accessible data to measure the current status of tourism in the region that comprises the waterway, LNG terminal, and pipeline components of the Bradwood Landing Project. Tourist activities could include trips to the lower Columbia River and ocean beaches via Highway 30 in Oregon or Highway 4 in Washington, visits to local museums and historical sites, and attendance at local festivals held periodically at Cathlamet, Skamokawa, and Astoria. About 18 ocean-going cruise ships each year come up the Columbia River to dock at Astoria, 24 miles down river from the LNG terminal. In addition, several smaller river cruise vessels travel between Portland and Astoria. The impact of tourism on the local economy includes revenue generated by sales of supplies, food, and beverage services; recreational outfitters (such as the local kayaking companies); and lodging. NorthernStar calculated that the annual tourist industry generates about \$361 million in travel spending in Clatsop and Columbia Counties, Oregon, and about \$204 million in travel spending in Pacific, Wahkiakum, and Cowlitz Counties, Washington (see table 4.8.2-8).

TABLE 4.8.2-8			
Direct Travel Impacts in the Vicinity of the Bradwood Landing Project			
Area	Travel Spending (\$ million)	Employee Earnings (\$ million)	Employment
Oregon	7,367.2	1,793.9	87,590
Clatsop County	351.9	106.8	5,290
Columbia County	26.1	5.0	370
Washington	12,701	3,833	143,660
Cowlitz County	112.8	27.6	1,630
Pacific County	104.0	28.8	2,080
Wahkiakum County	3.1	0.9	60
Sources: Dean Runyan Associates, 2007. State of Washington, Department of Community, Trade, and Economic Development, 2006.			

The operation of the Bradwood LNG terminal would not displace or remove any existing businesses. The closest businesses to the LNG terminal are the Columbia River Front Farm House and Columbia River Front Lodge, which both serve as vacation rental homes, located immediately across the Columbia River on Puget Island at CRM 39. There are at least three other bed and breakfast type accommodations on Puget Island (Redfern Farm, Rog's Retreat, and Columbia River Beach House). We believe that construction and operation of the LNG terminal would have no direct adverse affects on those

commercial establishments. Potential visual impacts on businesses in the vicinity of the LNG terminal are discussed in section 4.7.2.7.

One of the main potential impacts on tourism in the area would be project-related vehicle traffic. This was previously discussed in section 4.8.2.7. The impacts of LNG marine traffic on tourism related to use of the Columbia River was previously discussed in section 4.8.1.7.

4.8.2.9 Environmental Justice

Populations considered potentially affected for the environmental justice analysis due to the proposed LNG terminal include those communities occurring within the Zones of Concern associated with an LNG carrier while docked at the LNG terminal. Tables 4.8.2-9 and 4.8.2-10 describe the ethnic and racial composition and income distribution of these communities, respectively. Within these areas, there are no predominantly low-income or minority communities and the population of Native Americans is less than 2 percent of the total population. About 94 percent of the population of Puget Island is white non-Hispanic. Only 9.4 percent live below federal standards defining poverty. Similarly, 100 percent of the population of Clifton is white non-Hispanic and 14.4 percent live below the poverty line. Minorities comprise a smaller percentage of the population in both Puget Island and Clifton than the county average (6.6 and 6.9 percent, respectively). Poverty levels for both Puget Island and Clifton are slightly higher than Wahkiakum and Clatsop Counties (8.1 and 13.2 percent, respectively). However, based on the rural setting at the proposed LNG terminal site, neither low-income nor minority groups would be disproportionately affected by the project.

TABLE 4.8.2-9									
Demographics in the Vicinity of the Bradwood Landing LNG Terminal ^a									
State/County/Community	Total Population (2000)	Percent White	Percent Black or African American	Percent American Indian & Alaska Native	Percent Asian	Percent Native Hawaiian & Other Pacific Islander	Percent Other Race	Percent Hispanic or Latino – Any Race	Percent Minority
Oregon	3,421,399	86.5	1.6	1.3	2.9	0.2	7.5	8.0	13.5
Clatsop County	35,630	93.1	0.5	1.0	1.2	0.1	4.1	4.5	6.9
Clifton	33	100.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Washington	5,894,121	81.8	3.2	1.5	5.4	0.4	7.7	7.4	18.2
Wahkiakum County	3,824	93.4	0.3	1.6	0.5	<0.1	4.1	2.6	6.6

4.8.3 Pipeline Facilities

Construction and operation of the proposed pipeline would occur in Clatsop and Columbia Counties, Oregon and Cowlitz County, Washington. In addition, due to the large construction workforce, socioeconomic effects relating to construction of the pipeline would extend into Wahkiakum County and the Portland MSA, where approximately 86 percent of the construction workforce for the proposed pipeline is expected to reside. Because Columbia County is within the Portland MSA, there is some duplication of data in the discussion below.

TABLE 4.8.2-10				
Income Distribution in the Vicinity of the Bradwood Landing LNG Terminal ^a				
State/County/Community	Total Population (2000)	Per Capita Income (1999)	Median Household Income (1999)	Percentage of Persons Below Poverty (1999)
Oregon	3,421,399	20,940	40,916	11.6
Clatsop County	35,630	19,515	36,301	13.2
Clifton	33	14,549	28,438	14.4
Washington	5,894,121	22,973	45,776	10.6

Source: U.S. Census Bureau, Census 2000				

4.8.3.1 Population

The counties affected by the pipeline facilities vary widely in their population totals and densities (see table 4.8.2-1). No appreciable changes to the local population distribution or number are expected to occur as a result of the construction and operation of the proposed natural gas sendout pipeline. As described in section 4.8.2.1, NorthernStar indicated that the vast majority of its workers would reside within a radius of about 80 miles; however, NorthernStar has stated that some specialized out-of-state workers with previous pipeline construction experience may be employed for construction of the pipeline. For the purposes of this analysis, we have determined that the minimum number of specialized out-of-state workers required during construction of the proposed pipeline would be 10. Based on the average family size of 3.1 persons described in section 4.8.2.1, if 10 non-local workers are employed and bring their families, about 30 people would relocate to the area during construction of the proposed pipeline. We think the local population could easily absorb 30 more people without adverse effects.

4.8.3.2 Housing

Housing statistics for the counties affected by construction of the proposed pipeline are presented in table 4.8.2-2. Construction and operation of the pipeline facilities are not expected to affect housing in the study area. As discussed in section 4.8.2.1, NorthernStar would use mostly local workers. NorthernStar has estimated that as many as 30 people may temporarily relocate to the area as a result of the project. We think there is sufficient available housing to accommodate all non-local workers and their families.

4.8.3.3 Property Values

Comments were received during scoping regarding loss of income, use, and property value due to the proposed pipeline easements. The easements would give NorthernStar a right-of-way in which to construct, operate, and maintain the pipeline. In return, NorthernStar would compensate the landowner for use of the land. The easement agreement between NorthernStar and the landowner would specify compensation for damage to property during construction, loss of use during construction, and loss of renewable and nonrenewable or other resources. NorthernStar would seek to negotiate a mutually acceptable agreement. However, if the project is authorized by the FERC, that approval conveys with it the right of eminent domain under section 7h of the NGA. Therefore, if negotiations fail to produce an agreement, NorthernStar could initiate condemnation proceedings, and the value of the easement and the amounts for compensatory damages would be determined by the local district or state courts.

The impact a pipeline may have on the value of a tract of land depends on many factors, including the size of the tract, the values of adjacent properties, the presence of other utilities, the current value of the land, and the current land use. Subjective valuation is generally not considered in appraisals. This is not to say that the pipeline would not affect resale values. A potential purchaser of property may make a decision to purchase land based on his or her planned use, such as agricultural, future subdivision, or second home on the property in question. If the presence of a pipeline renders the planned use infeasible, it is possible that a potential purchaser would decide not to purchase the property. However, each potential purchaser has different criteria and differing capabilities to purchase land.

INGAA conducted a national case study to determine if the presence of a pipeline on a piece of property affected the property value or sales price of the property. The *INGAA Foundation Natural Gas Pipeline Impact Study* (INGAA, 2004) found that there was not a significant impact on the sales price of properties located along natural gas pipelines. It was further determined that neither the size of the pipeline (diameter) nor the product carried by a pipeline has any significant impact on sales price. Whatcom County, Washington also analyzed the impacts on property values associated with pipelines to determine the effect the Olympic pipeline explosion had on sales of real estate on or near the pipeline route. Its analysis determined that the explosion of the pipeline, which transported liquid petroleum fuel, had little effect on property values (Whatcom County, 2001).

4.8.3.4 Economy and Employment

The existing economic conditions in the pipeline project area are presented in table 4.8.2-3. As discussed in section 4.8.2.1, most of the labor force for construction of the pipeline facilities is expected to commute to the project area from within an 80-mile radius, including the Portland MSA. Tables 4.8.3-1 and 4.8.3-2 list the estimated construction workforce and the counties of residence that NorthernStar anticipates the workers to commute from, respectively.

TABLE 4.8.3-1		
Estimated Construction Workforce for the Pipeline Facilities		
Timeframe	Average Number of Workers per Month	Percent of Total Construction Workforce
HDD (months 1 - 8)	12	6.0%
Pipeline Construction (months 9 - 16)	133	74.5%
Peak Construction (month 13)	313	19.5%

TABLE 4.8.3-2			
Sources of Construction Workers for the Pipeline Facilities			
Location	Average Number of Workers Commuting	Percent of Workers Commuting	Number of Workers Commuting During Peak Construction
Clatsop County	3	2	6
Portland MSA	114	86	269
Columbia County ^a	8	6	19
Cowlitz County	13	10	31
Wahkiakum County	3	2	6
Pipeline Total ^b	133	100	313
<p>Note: Sum of addends may not be the same as the total due to rounding.</p> <p>^a Construction workers from Columbia County are also included in the Portland MSA; therefore, they are not included in the project total.</p> <p>^b Pipeline total does not include specialty workers that may be hired from outside the study area.</p> <p>Source: Columbia Pacific Building Trades Council, 2005.</p>			

NorthernStar estimates that 313 workers would be employed during peak construction of the pipeline, occurring during month 13 of pipeline construction. Approximately 86 percent of the construction workforce for the pipeline is expected to commute from the Portland MSA, including Columbia County. The remainder would commute from Cowlitz County (10 percent), Clatsop County (2 percent), and Wahkiakum County (2 percent). Workers are expected to commute to the project site daily and would generally work four 10-hour days per week.

Construction expenditures by NorthernStar would increase economic activity within the counties affected by the project, which would have a multiplier effect on the local economy (see section 4.8.2.4). Table 4.8.3-3 shows the estimated economic impact of construction of the pipeline facilities.

TABLE 4.8.3-3					
Economic Impacts of Construction of the Pipeline Facilities					
Impact	Project Total	Four-county Area Impact (30 percent of estimated workforce)			
		Direct Impacts	Output Multiplier ^a (approximate)	Indirect and Induced Effect	Total Four-county Impact
Economic Impact ^b	\$126,000,000	\$10,320,000	1.82	\$8,542,200	\$18,862,200
Payroll ^c	\$22,000,000	\$4,400,000	1.64	\$2,816,000	\$7,216,000
Employment ^d	133	27	1.72	36	73
^a IMPLAN calculates the results of the multipliers based on a per million dollar change in final demand (total direct expenditures).					
^b Payroll and expenditures over 16-month pipeline construction period.					
^c Payroll over 16-month pipeline construction period.					
^d Based on monthly averages.					

Project-related employment and expenditures would have a direct and positive effect on employment and economy within the study area. Total construction costs for the pipeline facilities are estimated to be \$126 million. NorthernStar estimates that total payroll (which includes both wages and benefits) for the construction of the pipeline facilities would be \$22 million. Within the four-county area, NorthernStar estimates that total direct expenditures on goods, equipment, and services during construction of the pipeline facilities would be \$10.3 million.

NorthernStar anticipates that the first 8 months of pipeline construction would be required to complete the HDDs. The following 8 months would be required to complete the rest of the pipeline. The average local monthly payroll during pipeline construction would be about \$550,000. Based on NorthernStar's estimates for where workers would reside, the average payroll dollars per month generated by workers would be \$275,000 in Cowlitz County, \$165,000 in Columbia County, and about \$55,000 per month in both Wahkiakum and Clatsop Counties.

4.8.3.5 Tax Revenues

Construction and operation of the Bradwood Landing Project would have beneficial impacts on property and corporate tax revenue in the counties affected by the project. Property taxes on the pipeline would be assessed by and paid to Clatsop and Columbia Counties in Oregon and Cowlitz County in Washington. Property taxes for a piece of property are generally based on the actual use of the land. Pipeline construction would not change the general land use, but future construction of aboveground structures on the permanent right-of-way would be precluded. Based on the portion of the pipeline in each of the counties and tax rates from the different taxing entities, the apportioned amounts of the property taxes paid would be approximately \$284,029 to Clatsop County, \$518,465 to Columbia County,

and \$740,250 to Cowlitz County. NorthernStar has estimated that total pipeline property taxes would be \$1,542,744.

In addition to the state taxes described above, Washington municipal taxes may apply. Cities and towns in Washington are allowed to impose local Public Utilities and Business and Occupation Taxes. For example, the City of Longview, which is the principal city in Cowlitz County, imposes a Public Utilities Tax of 6 percent of gross receipts on any company in the business of “furnishing or distributing natural gas.” It is not clear whether merely transporting natural gas is subject to tax. Longview also imposes a Business and Occupation tax at the rate of 0.2 percent on service businesses. This tax apparently would apply if the city’s Public Utilities Tax does not apply. Applying today’s rates, NorthernStar estimates that its local tax liability may range between \$30,000 and \$1,200,000, depending on which tax applies. This liability may be less, and possibly zero, if NorthernStar’s gross receipts from gas transportation activities are apportionable outside any city limits.

4.8.3.6 Local Infrastructure and Public Services

As discussed in section 4.8.2.6, a range of public services are provided in the cities and counties in the vicinity of the LNG terminal, which also includes the area of the pipeline. Table 4.8.1-4 provides an overview of existing hospitals, ambulance services, fire departments and law enforcement in the vicinity of the proposed project, including the pipeline. A discussion of the potential impacts of the proposed project on local hospitals, ambulance services, utilities, and schools is provided in section 4.8.2.6. A discussion of potential impacts on local fire protection districts and law enforcement agencies is provided below.

Fire protection along the western portion of the pipeline route in Oregon would be provided by the Westport Wauna Fire District, Knappa-Svensen-Burnside RFPD in Clatsop County, and the Clatskanie RFPD in Columbia County, with support from the ODF for the rural fire protection districts. Along the eastern portion of the pipeline route in Washington the closest fire protection district is the Cowlitz County Fire Protection District No. 6, which serves the Longview area. Due to the largely rural setting through which the proposed pipeline would pass, law enforcement would be provided by the Clatsop County Sheriff’s Office, Columbia County Sheriff’s Department, and the Cowlitz County Sheriff’s Office.

Fire and other emergencies along the proposed route could require the services of local fire departments and law enforcement agencies, as discussed above. Both Clatsop County and the City of Clatskanie, Oregon have commented about concerns that the project may result in a strain on current resources to provide fire protection in the case of an emergency involving the LNG terminal and associated pipeline.

NorthernStar filed its first draft ERP on March 24, 2008. The ERP includes a cost-sharing plan that outlines how NorthernStar would fill resource gaps and supplement the first-responder capabilities of the local communities near its proposed LNG terminal. The ERP is discussed in more detail in section 4.11.6.

In addition, as discussed in section 4.11.9, due to current safety regulations governing the construction design, monitoring, and operation of interstate natural gas pipelines, we believe the potential for an accident involving the sendout pipeline is very low. Therefore, we do not believe that construction and operation of the proposed pipeline would result in adverse impacts on local infrastructure and public services.

4.8.3.7 Transportation and Traffic

Construction of the pipeline facilities could affect transportation and traffic in the project area by increasing the number of vehicle trips per day on area roads as a result of commuting and construction vehicle traffic as well as temporarily closing some minor roads during pipeline construction. A map of the project area is included as figure 2.1-1.

As previously discussed, during construction of the Bradwood Landing Project, NorthernStar anticipates an average of 30 trucks per day delivering construction equipment and supplies to the LNG terminal and along the pipeline route. However, during peak construction, up to about 80 trucks would make deliveries to the LNG terminal and along the proposed pipeline route. NorthernStar is currently consulting with Clatsop County regarding impacts on traffic due to construction vehicle traffic along Clifton Road (see section 4.8.2.7).

Pipeline construction workers would park their vehicles at the construction parking area located southeast of the Taylorville interchange at Highway 30. Buses would then be used to move workers to the job site. In addition, NorthernStar has committed to establishing policies to encourage workers to use carpooling and vanpooling to further reduce the potential for traffic impacts.

Additional vehicle traffic would result from equipment or material deliveries into and out of the proposed pipe storage and contractor yards each day. NorthernStar would use existing public and private roads that intersect the right-of-way to obtain access during construction. Load limits on public roads would be observed to prevent damage to the road surface, road bed, culverts, and bridges. Access road modifications proposed by NorthernStar are limited to grading and the addition of gravel to prevent rutting. Upon completion of the pipeline facilities installation, previously existing roads that were used for access would be returned to original or better condition, or as otherwise requested by the landowner.

NorthernStar would apply for all permits necessary for road access and crossings, and would comply with all permit stipulations. Any special requirements due to traffic volumes and weight limitations would be addressed via this process. Additionally, NorthernStar would coordinate construction activities with jurisdictional highway authorities, emergency responders, school transportation departments, other local groups such as private homeowners associations, and individual homeowners to minimize traffic impacts associated with the construction of the pipeline. Traffic flow for general access, and in particular for emergency response, would be maintained along roads which are the sole access to homes and communities.

NorthernStar and all contractors associated with the project would comply with all posted speed limits, and would exercise good judgment with regard to safe speeds in potentially hazardous situations. Temporary speed limits may be required in work zones to assure safe passage for vehicles, and would be posted where necessary.

Traffic impacts associated with the pipeline construction would be localized and temporary. NorthernStar would video or photograph access roads and crossing locations prior to construction or utilization of the roadway to establish a record of the pre-existing condition. Any damages to roadways associated with the construction of the pipeline, including access, would be repaired to the pre-existing condition. During construction, roadways would be maintained in a passable condition utilizing temporary repairs if necessary.

Pipeline construction across major roads would be accomplished by boring or HDD under the roadbed. Boring requires temporary extra workspace on both sides of the crossing for excavating bore pits to the depth of the pipeline. The bore pits are typically located just outside of the road right-of-way limits; however, site-specific conditions such as the presence of structures or waterbodies may require the

bore pits and temporary extra workspace to be moved within the road right-of-way. Little or no disruption of traffic would occur at road crossings that are bored. Most smaller, unpaved roads and driveways would be open-cut, then restored to preconstruction conditions or better. If an open-cut crossing were to require extensive construction time, provisions would be made for temporary detours or other measures to allow for the safe flow of traffic during construction. Table 4.8.3-4 lists the roads and highways crossed by the pipeline route and NorthernStar's proposed crossing method.

These increased traffic levels associated with construction of the pipeline would be temporary and limited to the period of construction (about 16 months).

We received comments on the draft EIS regarding potential impacts on narrow roads that have been identified by NorthernStar as proposed access roads to be used during construction of the pipeline (e.g., Whitewater Road, in Cowlitz County, Washington). The commentor identified this as a 1.5-lane road with blind corners and no turnouts for passing traffic. It is possible that use of these types of roads would not be feasible without some additional improvements (e.g., widening) to accommodate the large trucks and vehicles that would be required during construction. In addition, the ODOT, in its comments on the draft EIS stated that it would need to reevaluate traffic impacts at the Clifton Road intersection after NorthernStar submits its road approach application. The ODOT identified preliminary mitigation measures that would be required, including construction of a left turn lane on Highway 30 at Clifton Road, widening the highway shoulder to accommodate right turning vehicles, and radii improvements. Therefore, **we recommend that:**

- **NorthernStar should consult with the ODOT, WDOT, and appropriate local agencies in the development of its final traffic management plan. The final traffic management plan should include the design for improvements along Highway 30 and Clifton Road, and measures to reduce impacts on narrow roads that would be used to access the construction right-of-way. Prior to construction of the LNG terminal and pipeline, NorthernStar should file with the Secretary its final traffic management plan, and documentation of consultations with the ODOT, WDOT, and local county government agencies, with the Secretary for the review and written approval of the Director of OEP.**

4.8.3.8 Recreation and Tourism

The Bradwood Landing pipeline would not directly affect any national, state, county, or local parks or designated recreation and public interest areas. The HDD under the Columbia River between MPs 19.0 and 19.8 should avoid impacts on the LCNHT and Lower Columbia River Water Trail, and islands in the Columbia River that form part of the JBHNR. The Bradley State Scenic Viewpoint is located about 1,000 feet west of MP 1.7. There are parks and recreational facilities in the City of Clatskanie, about 2.5 miles south of the pipeline around MP 13.4, and in the Cities of Longview and Kelso, about 4 miles south of the pipeline in the vicinity of MP 34. These recreational and public use areas are discussed in section 4.7.3.6.

The primary potential impact on recreation and tourism in the area resulting from construction and operation of the pipeline would be project-related vehicle traffic. This was previously discussed in section 4.8.2.7. Visual impacts are addressed in section 4.7.3.7.

^a Roads, railroads, utilities, and pipelines were digitized manually based on photo interpretation and available desktop data.

^b The crossing methods were identified based on photo interpretations of the crossed features. The actual crossing methods used during construction may vary depending on the conditions and features of the roads and railroads and in accordance with applicable permits.

4.8.3.9 Environmental Justice

Tables 4.8.3-5 and 4.8.3-6 describe the ethnic and racial composition and income distribution of the counties and communities crossed by the pipeline route. There are no predominantly low-income or minority communities in the area surrounding the pipeline facilities. Therefore, these groups would not be disproportionately affected by the project.

TABLE 4.8.3-5									
Demographics of Communities Crossed by Bradwood Landing Pipeline Route

4.9 CULTURAL RESOURCES

Section 106 of the NHPA, as amended, requires that the FERC take into account the effects of its undertakings (including authorizations under sections 3 and 7 of the NGA) on properties listed on, or eligible for listing on, the NRHP, and to provide the ACHP an opportunity to comment on the undertaking. NorthernStar, as a non-federal party, is assisting the FERC in meeting its obligations under section 106 and the implementing regulations at 36 CFR 800.

The COE and Coast Guard also have responsibilities for considering effects of their undertakings on historic properties, under the NHPA. However, as lead federal agency for this project, the FERC will address compliance with the act jointly for all cooperating agencies in this EIS.

4.9.1 Results of Cultural Resources Overviews and Inventories

NorthernStar's cultural resources consultant (Historical Research Associates, Inc. (HRA)) conducted archival research and a site file search at both the Oregon and Washington SHPOs in June 2005. HRA met with the Oregon SHPO in July 2005 to discuss the proposed project. The Oregon SHPO indicated that a submerged survey of the proposed turning basin in the Columbia River for the LNG terminal was not necessary. In January 2006, HRA consulted with Washington SHPO about the area of potential effect (APE) for the pipeline. NorthernStar's cultural resources contactors (HRA and URS) have conducted inventories of portions of the APE that were accessible, and have submitted reports to the FERC and the SHPOs. The survey reports included overviews and the results of the inventories, which are discussed below.

4.9.1.1 Waterway for LNG Marine Traffic

In a letter dated November 24, 2006, we requested the opinion of the Washington SHPO about the potential for LNG marine traffic to affect historic properties along the waterway to the proposed Bradwood Landing LNG terminal. In response, the Washington SHPO, in a letter to the FERC dated November 27, 2006, requested a description and map of the APE for the LNG marine transit route.

In a January 4, 2007 data request, we asked NorthernStar to provide the Washington and Oregon SHPOs with maps and a narrative description of the APE for the LNG carrier transit route along the Columbia River from the sea buoy to the proposed Bradwood Landing LNG terminal, and consult with the SHPOs regarding the potential for LNG marine traffic to have any adverse effects on historic properties. In a January 16, 2007 filing, NorthernStar indicated that it would provide the requested data to the SHPOs in early February 2007 and expected to complete consultations on this issue by mid-April 2007. On March 13, 2007, we requested that NorthernStar address the potential impacts LNG marine traffic may have on historic properties along the waterway and within the Zones of Concern. NorthernStar responded to that request with a filing on May 10, 2007.

NorthernStar's May 10, 2007 filing identified 19 known shipwrecks within the Columbia River adjacent to the LNG marine traffic route in Oregon. In addition, 18 shipwrecks have been recorded along the Pacific Coast west of Fort Stevens State Park in Oregon overlapped by the Zones of Concern. One shipwreck, the *Isabella*, near Astoria, Oregon, is listed on the NRHP. The NRHP eligibility of the other shipwrecks is unknown. LNG marine traffic to the Bradwood Landing LNG terminal would have virtually no potential to impact any of those shipwrecks, because the shipwrecks are situated in shallow water outside of the currently maintained navigation channel, and an LNG carrier that loses steerage and strays away from the navigation channel would likely run aground before reaching the location of any of the shipwrecks.

The LCNHT follows the lower Columbia River to its mouth. While there are numerous campsites related to the 1804-1806 Lewis and Clark expedition along the lower Columbia River, none have been recorded as archaeological sites.

The LCNHP consists of 12 park sites near the mouth of the Columbia River, stretching from Long Beach, Washington to Cannon Beach, Oregon. Two elements of the LCNHP, Cape Disappointment State Park (including the Lewis and Clark Interpretive Center) in Washington, and Fort Stevens State Park in Oregon, would be overlapped by the Zones of Concern for LNG marine traffic in the waterway to the proposed Bradwood Landing LNG terminal. The other 10 elements of the LCNHP are outside of the Zones of Concerns and would not be affected by the project. LNG marine traffic in the waterway would have no adverse effects on the LCNHT and the LCNHP. Our reasons supporting this determination are explained below.

There are multiple sites listed on the NRHP along the shoreline of the Columbia River within the Zones of Concern in the state of Washington, including two historic districts. The Cape Disappointment Historic District was listed on the NRHP in 1975 and covers 18,000 acres. It includes eight structures, including the Cape Disappointment Lighthouse, originally completed in 1856, and the remnants of Fort Canby, a military installation established in 1875. The Skamokawa Historic District was listed on the NRHP in 1976, covers 8,000 acres, and includes 21 primary and 56 secondary structures. At Altoona, the Double-ended Columbia River Gillnet Boat was listed on the NRHP in 1978 as an individual structure. There are three NRHP-listed sites in Cathlamet: the Pioneer Cemetery (45WK58), Kimball-Butler House (45WK59), and Pioneer Church (45WK60).

There are also a number of NRHP-listed sites along the waterway and within the Zones of Concern in Oregon, including the Fort Stevens Military Reservation (35CLT85), added as an individual site in 1971. In Warrenton, the Daniel Knight Warren House is listed on the NRHP as a single dwelling. There are three NRHP Historic Districts in Astoria: the Astoria Downtown Historic District, listed on the NRHP in 1998, encompassing 540 acres and including 61 contributing buildings or structures and 64 non-contributing resources; the Uniontown-Alameda Historic District, listed in 1988, covering 754 acres and including 134 contributing elements and 82 non-contributing; and the Shively-McClure Historic District with 241 contributing and 171 non-contributing resources. Individual structures listed on the NRHP in Astoria include: the Astor Hotel, Astoria Column, Bartlett House, Cherry House, Old City Hall, County Courthouse, Old County Jail, Doughboy Apartments, Elks Building, Elmore Cannery, Elmore Salmon Cannery, Erickson-Larsen Ensemble Building, Erickson-Larsen House, Fire House No. 2, Ferguson House, Fisher House, three Flavel houses, Foard House, Fort Astoria, Gilbert House, two Grace Episcopal Churches, Gray House, Griffin House, Hobson House, Holmes House, Jualo-Palo House, Kinney Cannery, Leinenweber House, Liberty Theater, Lightship Columbia, Macklin House, Noonan-Norblad House, Page House, Post Office, Rovainen House, Seeborg House, Structure at 229 Alameda, Structure at 265 Alameda, Structure at 110 Washington, Svensen Blacksmith Shop, Union Fishermens Coop, Victory Monument, Wharf and Bonded Warehouse, Andrew Young House, and Benjamin Young House.

It is highly unlikely that LNG marine traffic in the waterway to the proposed Bradwood Landing could have any adverse effects on historic properties in the lower Columbia River or along its shoreline. About 125 LNG carriers per year would transit to the proposed terminal, which would represent an increase of about 7 percent in commercial vessel traffic on the Columbia River. In our opinion, use of an existing dredged navigation channel would have little potential to impact submerged historic properties within the navigation channel. In addition, we think the potential for effects on shoreline cultural resources along the LNG marine traffic route would be low. LNG marine traffic should not result in significant shoreline erosion affecting historic properties. Further discussions about LNG marine traffic, and potential shoreline erosion are provided elsewhere in this EIS.

Commentors on our draft EIS raised concerns about the potential for leaks from LNG carriers having impacts on historical parks and trails located along the waterway, and potential visual impacts on visitors to the parks. We discuss potential visual impacts on recreational resources from LNG marine traffic in the waterway in section 4.7.1.5. LNG carriers would be visible to users of the various elements of the LCNHP along the shore of the lower Columbia River for several minutes at a time. These carriers would represent only a minor increase to the current use of the river by commercial vessels.

As discussed in section 4.3.2.2, LNG carriers are double hulled, which would assure that fuel and oil are kept on board, and makes the potential for a fuel or oil spill unlikely. Furthermore, each LNG carrier would maintain a SOPEP as required by international convention.

In the unlikely event of an LNG carrier incident that would result in an LNG spill and fire, effects would vary for different kinds of historic properties, depending upon their location within the different Zones of Concern. There would be less impacts on sites located in Zone 3 compared to sites located in Zone 1. Historic buildings could be affected by a pool fire, while a buried prehistoric site may not. However, a buried archaeological site may be affected by a fire-fighting response, such as the use of bulldozers to clear a fire break. Adverse effects from a project-related fire could be minimized by coordination with fire suppression agencies. NorthernStar indicated that it would produce a Cultural Resources Management Plan that would outline procedures for coordination with first responders in order to protect historic properties in such situations. With the implementation of NorthernStar's proposed safety and security measures and the conditions outlined in the Coast Guard WSR, the possibility of an LNG spill and associated pool fire from an LNG carrier en route to the terminal is very low, and impacts on historic properties along the waterway or within the Zones of Concern would be less than significant.

4.9.1.2 LNG Terminal

A portion of the LCNHT follows the lower Columbia River. The Lewis and Clark expedition camped on November 6, 1805 in the vicinity of Cape Horn, opposite of Puget Island, in modern Wahkiakum County, Washington, toward the end of their journey westward to the Pacific Ocean. The next day they proceeded by canoe, with a local Native American guide, down the north side of the Columbia River, and camped on November 7, 1805 west of Jim Crow Point, opposite of Pillar Rock, in Wahkiakum County, Washington. The Lewis and Clark expedition spent the winter of 1805-1806 at Fort Clatsop, west of modern Astoria, Oregon, and in March of 1806 began their return journey up the Columbia River eastward. Taking their canoes along the south side of the river, they camped on March 23, 1806 just below the mouth of John Day River in Clatsop County, Oregon. On March 24, 1806, they camped at Aldrich Point, Clatsop County, Oregon, and on March 25, 1806, they camped just below the mouth of the Clatskanie River in Columbia County, Oregon (Moulton, 2002). There are no known Lewis and Clark campsites at the Bradwood Landing LNG terminal location.

During their trip through the project area, Lewis and Clark identified the Native Americans near the mouth of the Columbia River on the north (Washington) side as members of the Wahkiakum Tribe, while the Native Americans on the south (Oregon) side were referred to as the Cathlamet Tribe. Modern ethnographers group both the Wahkiakum and Cathlamet bands together within the Cathlamet linguistic division of the Lower Chinook Nation (Silverstein, 1990). Ray (1938) mapped an ethnohistoric Indian village at the mouth of Coal Creek in Cowlitz County, Washington, two villages in the vicinity of the modern town of Cathlamet, Washington, one on Tenasillahe Island, and one near modern Knappa, Oregon. Lewis and Clark noted an Indian cemetery, with the dead entombed in canoes raised above the ground, at the Cathlamet village in the vicinity of Knappa (Moulton, 2002). An archaeological site near Knappa has been recorded as 35CLT37 (also called Hlilusqahih or the Knappa Docks Site), and was listed on the NRHP in 1984. Also listed on the NRHP in 1984 was the Indian Point Site, recorded as 35CLT34, near Svensen, Oregon.

The LCNHT through the project area has not been officially documented or nominated for the NRHP. HRA considers the LCNHT to be potentially eligible for the NRHP. According to the NPS Trail Manager, the LCNHT in this area is not owned or maintained by the NPS, but rather should be managed by the agencies with jurisdiction over the waterway, including the COE and the ODSL (Bowden et al., 2006a).

In response to a comment on the draft EIS from the DOI, FERC staff contacted Dan Wiley, Chief of Integrated Resources Stewardship for the NPS in Omaha, Nebraska, to obtain his comments and concerns about the project prior to the production of this final EIS. Mr. Wiley stated that his main concern about potential project impacts on the LCNHT was that the locations of Lewis and Clark campsites derived from the historical literature may not be correct. However, he indicated that there have been no comprehensive surveys of the LCNHT along the lower Columbia River, or recent investigations by the NPS, or other scholars, to identify new potential locations for Lewis and Clark campsites in the project vicinity (Wiley, 2008)

The Bradwood Landing LNG terminal would have no adverse effects upon the LCNHT, because no physical remnants of the Lewis and Clark expedition have been recorded in the APE, and LNG marine traffic and NorthernStar's proposed dredging for the turning basin is similar to and consistent with current activities in the Columbia River. The Columbia River navigation channel is utilized by about 2,000 commercial ships traveling to upriver ports each year, and is dredged and maintained by the COE. HRA's cultural resources survey of the proposed LNG terminal tract found no archaeological sites that can be associated with the Lewis and Clark expedition. Moreover, the place where the main terminal facilities would be situated at Bradwood Landing is covered with fill from past river dredging; thus any potential archaeological sites pre-dating the twentieth century in this area would be deeply buried beneath the dredge piles.

As a result of its literature review and file search, HRA identified two previous cultural resources investigations that covered portions of the LNG terminal tract, and two other archaeological surveys nearby (one covering part of Tenasillahe Island and one covering a small area on Puget Island). None of these investigations recorded any cultural resources; although one report mentioned an unrecorded prehistoric site at the former townsite of Bradwood. The closest previously recorded site to the LNG terminal is a prehistoric midden, site 35CLT32, located about 2,674 feet northwest of the APE for the terminal, at the southern shore of Clifton Channel.

HRA speculated that there may be an unrecorded prehistoric site at the northeastern end of the parcel controlled by NorthernStar for its LNG terminal, adjacent to where an 1871 river chart showed the location of "Joe's Fishery." This was an historic fishing spot in the Columbia River, on the south side of Puget Island, named after Joe Falangus, a Greek fish buyer who settled at Clifton, Oregon (Helwig, 2000), a town located about 1 mile west of the Bradwood LNG terminal. HRA indicated that it could not find the exact location of the potential Joe's Fishery archaeological site because the construction of the railroad and an historic basalt mining operation may have modified the topography in the area of Hunts Mill Point.

The 1871 river chart labeled the point of Oregon shore adjacent to "Joe's Fishery" as "Hunts Mill Point." Through archival research, HRA identified the location of the historic Henry Hunt homesite and lumber mill, operated from about 1843 to 1852, along Hunt Creek within NorthernStar's LNG terminal property. However, the location of the Hunt mill has not yet been examined with an on-the-ground cultural resources survey, and this potential historic-archaeological site is currently unrecorded.

HRA also mentioned a lumber mill built by A.W. Clark and J.B. Robinson in 1910 and operated by the Oregon Timber and Lumber Company (OTLC). This mill was associated with a logging railroad

that the 1930 Metzger map showed going up along the west side of Hunt Creek from its mouth. The exact location of the OTLC mill has not yet been clearly identified; nor has it been recorded as an historic-archaeological site. The logging railroad has also not yet been recorded.

The Astoria and Columbia River Railroad (ACRR, now called the PWRR) was completed between Astoria and Goble, Oregon in 1898, and was acquired by the Northern Pacific Railroad in 1911 (Helwig, 2000). In the terminal area, historic maps show the rail stop of “Parsons,” named after the 1895 landowner. HRA recorded the ACRR within the terminal property as an historic-archaeological site and evaluated the railroad as potentially eligible for the NRHP.

In August 2005, HRA conducted a walkover survey covering 28 acres at NorthernStar’s LNG terminal property, with limited shovel testing. The survey recorded historic-archaeological site 35CLT88, which represents the remains of the historic townsite of Bradwood and the associated Bradley-Woodard lumber mill. The physical remains still extant at this site include dock pilings along the shore (representing the remains of the mill dock and logging railroad trestle to the mill); a concrete foundation (related to a mill); a mill pond; a concrete structure (possibly the vault at the former mill office); an open-air pole barn (built about 1985); and associated artifacts, including metal barrels, bottle glass, ceramic sherds, bricks, and concrete, lumber, and metal fragments. The majority of the site is covered with dredge material piles, deposited between 1966 and 2003.

Fred Bradley of Michigan began acquiring timber land in the project area around 1901, and in 1930 formed the Bradwood-Woodard Lumber Company in partnership with Walter Woodard of Cottage Grove, Oregon. They contracted with the COE to bring in dredged material from the Columbia River, on top of which they built a new mill at Parsons, which started operations in 1934, specializing in hemlock and silver fir. The old OTLC logging railroad along Hunt Creek was rebuilt and extended up the slopes of Nicolai Mountain to the south, and was ready for the first trains (using a Shay locomotive engine) to run by 1932. The logging railroad operated until the summer of 1938, and was conveyed on a trestle to a log dump at the river. After that, logs were trucked in, and dumped into the mill pond. The mill complex included a planing mill, chipping mill, wigwag burner and drying kilns, dry storage building, train maintenance building, powerhouse, and main office. Finished lumber was taken out by ships via the dock. West of the mill dock, the U.S. Navy built a pier and observation house in the early 1940s. In 1958, Pacific Power and Light ran a 12-kV electric power line into Bradwood and Clifton. At its peak, operating as the Columbia Hudson Lumber Company, the mill had about 170 employees (Helwig, 2000).

The company town of Bradwood was erected adjacent to the lumber mill by 1934. The town originally consisted of a Main Street lined by 23 homes. Additional buildings included a boarding house, about 13 bachelor’s quarters, cookhouse, bathhouse, a nurse’s/doctor’s office, a union hall, a school (which operated from 1932 to 1942), and a company store, which also housed the post office. At the time of the mill’s closing in 1962, there were 47 residences in the town of Bradwood.

A portion of the mill burned in a fire in 1965. Analysis of a 1966 aerial photograph showed only the planing mill, office, train maintenance shop, and another building visible north of the railroad. The logging railroad tracks and trestle had been removed. Most of the houses at the eastern end of Bradwood were still standing in 1966, but the bachelor houses and garages on the west end of town had been torn down. Only eight houses were observed in a 1978 aerial photograph, and the pier to the former Navy observation house had been removed by that date (AMEC, 2005). A former resident visiting Bradwood in 1983 found only the store and four houses, in various states of disrepair, remained. The mill complex was in ruins. The last five residents of Bradwood left in 1985. In 1998, the same visitor noted that all buildings were gone, and the townsite bulldozed (Helwig, 2000).

In 1946 Bradley-Woodard sold the mill to Don Buchanan and Associates, operating as the Bradwood Lumber Company. A year later it passed to the Columbia Hudson Lumber Company. A portion of the townsite was acquired in 1946 by Roy Leonard, the first plant manager and secretary for the Bradley-Woodard Company, and first Bradwood postmaster. The property was acquired by the Starker family in 1977, and then was transferred in 1987 to a partnership which included Kenneth Leahy, who became sole owner in 2001. The Bradwood site has been used to receive materials dredged from the Columbia River by the COE, with documented fill disposal events occurring in 1966 (274,000 cubic yards), 1973 (217,000 cubic yards), and 2002 (382,000 cubic yards). Mr. Leahy intended to sell the dredged material as masonry sand, and export it by rail, but testing of the material indicated it was not suitable for that purpose (AMEC, 2005).

HRA evaluated the Bradwood site as not eligible for the NRHP. NorthernStar provided a copy of its LNG terminal cultural resources survey report to the Oregon SHPO on February 9, 2006. A revised copy of this report (Bowden et al., 2006a) was filed with the FERC on November 16, 2006.

4.9.1.3 Pipeline Facilities

A literature and site file search conducted by HRA in June 2005 revealed that 27 previous archaeological investigations have been conducted within 0.5 mile of the proposed pipeline route. Eight sites have been previously recorded within 150 feet of the pipeline. A 1991 survey of the KB Pipeline, which would be paralleled by a portion of the NorthernStar pipeline, recorded no cultural resources.

The LCNHT follows the lower Columbia River, although the portion of the trail through the project area has not been documented or nominated to the NRHP. The NPS does not own or manage any lands associated with the LCNHT along the lower Columbia River. Ownership of the river is divided between the states of Oregon and Washington, with the shoreline in the project area mostly under private control. No Lewis and Clark campsites have been recorded along the pipeline route. The proposed pipeline would cross under the Columbia River using HDD methods between about MPs 19.0 and 19.6.

During their westward journey down the Columbia River, the Lewis and Clark expedition camped near the mouth of the Kalama River, in what is now Cowlitz County, Washington, on November 5, 1805, and camped near Cape Horn, Wahkiakum County, Washington, on November 6, 1805. In his journal, William Clark mentioned an abandoned Indian village on the north side of the Columbia River, just past the mouth of the Cowlitz River. The next day the expedition stopped briefly at a Wahkiakum Indian village of four houses, where they traded fish hooks for roots, some fish, three dogs, and two otter skins.

On the return trip east, up the Columbia River, the Lewis and Clark expedition camped near the mouth of the Clatskanie River in Columbia County, Oregon, on March 25, 1806. They wrote of visiting a Cathlamet fishing camp on Puget Island, and another Cathlamet camp near the mouth of the Clatskanie River. The next day they camped on an island (maybe Walker or Dibble Island) in the river near present-day Longview. On March 26, 1806, Lewis and Clark noted an “old village” opposite the lower end of what they called “Fannys Island” (probably Crims Island) in Columbia County, Oregon, where they met Cathlamet Indians, giving metals to their chiefs and receiving roots and fish in return (Moulton, 2002).

Meriwether Lewis, on March 27, 1806, indicated that the principal village of the “Skillutes” was located a few miles above the mouth of the Cowlitz River. In 1811, the fur trader Gabriel Franchere called them the “Kreluit” Indians (Franchere, 1854). Ray (1938) clarified that this was probably the Cowlitz tribe, and labeled this village “Mansela.”

At Port Westward, archaeological investigations at site 35CO16 yielded numerous aboriginal artifacts and perhaps human remains. The fur trader Alexander Ross in 1811 mentioned “the great Whill Wetz village” was situated on the north side of the Columbia River at Oak Point (Ross, 1849). George Gibbs, who went down the Columbia River by steamboat as part of Issac Stevens’ railroad survey expedition in 1853-1855, called this the village of Coonaic. HRA believes that NorthernStar’s HDD under the Columbia River should avoid impacting site 35CO16.

HRA pointed out that the pipeline would pass near the Abernathy Cemetery, dating to 1866, including the graves of Alexander Abernathy, one of the first Euro-Americans to settle around Oak Point in the 1850s, and his family. The Abernathy Cemetery, containing about eight headstones, located on the former land claim of Alexander Abernathy, is surrounded by a white rail fence, and currently maintained by the local community (Taylor, 1964). It is illustrated on the USGS topographic quadrangle map at about MP 19.7. The cemetery, which has not yet been recorded as an archaeological site, should be avoided by NorthernStar’s HDD under the Columbia River.

At about MP 3.9 the pipeline would cross the ACRR/PWRR, completed in 1898. HRA believes the ACRR is potentially eligible for the NRHP. However, it appears that the portion of the railroad crossed by the pipeline has not yet been recorded or specifically evaluated in terms of integrity. Adverse effects on the railroad would be avoided because the pipeline would be installed beneath the railroad through conventional bore methods.

HRA inspected a 200-foot-wide corridor along the pipeline route in locations where NorthernStar had obtained landowner permission. As of October 2006, about 25.2 miles of the proposed route had been surveyed for cultural resources. No new archaeological sites were recorded during this survey. HRA believes that the proposed Bradwood Landing pipeline should avoid or have no effect on previously identified or recorded sites 35CLT32, 35CO12, 35CO14, 45CW2, the Abernathy Cemetery, and the Bradwood Mill and Town (35CLT88). The project should have no adverse effects on the ACRR, LCNHT, and 35CO16. Previously recorded sites 35CO11 and 45CW124 still need to be evaluated because they are located within parcels which have not yet been surveyed. A revised survey report for the pipeline (Bowden, et al., 2006b) was filed with the FERC on November 16, 2006.

4.9.1.4 Ancillary Facilities

URS conducted a cultural resources inventory of the proposed power line to the LNG terminal, including an alternative power line route and an access road. In total about 82 acres were inspected, including a 100-foot-wide corridor along 1.6 miles for the originally proposed power line route, 1.5 miles for the new preferred alternative, and 3.5 miles along the proposed access road. URS identified seven isolated finds and one site during its power line surveys. All of the isolated finds are remains of historic tree stump springboard scars, recommended as not eligible for listing on the NRHP. The site is a segment of the historic route of U.S. Highway 30 (field designation PL8), originally constructed in about 1921 as a gravel road, paved in about 1930, and abandoned when a new road alignment was built in about 1956. URS believes the road segment it recorded in the APE is not eligible for the NRHP because it lacks integrity.

In addition, URS documented a cultural resources inventory of 5 acres at the intersection of modern Highway 30 and Clifton Road. No cultural resources were identified at this location. On August 21, 2006, NorthernStar filed a revised cultural resources inventory report (McDaniel and Kelly, 2006) covering the power line.

4.9.2 Unanticipated Discovery Plan

The cultural resources inventory report for the LNG terminal, filed February 22, 2006, included a Plan and Procedures for the Unanticipated Discovery of Cultural Resources and Human Remains (Discovery Plan). This plan addressed comments provided by the Oregon SHPO in a January 20, 2006 filing by the ODE on an earlier submitted draft Discovery Plan. A Discovery Plan was filed by NorthernStar for the pipeline on March 14, 2006. The Oregon SHPO requested a revision to the Discovery Plan in its April 4, 2006 review of NorthernStar's cultural resources reports. NorthernStar filed a revised Discovery Plan for the LNG terminal on August 21, 2006, and filed a revised Discovery Plan for the pipeline on November 6, 2006.

4.9.3 Native American Consultation

The FERC acknowledges that it has trust responsibilities to Indian tribes, and so, on July 23, 2003, it issued a "Policy Statement on Consultations with Indian Tribes in Commission Proceedings" in Order 635. That policy statement included the following key objectives:

- The Commission will endeavor to work with Indian tribes on a government-to-government basis, and will seek to address the effects of proposed projects on tribal rights and resources through consultations; and
- The Commission will assure that tribal resources and interests are considered whenever the Commission's actions or decisions have the potential to adversely affect Indian tribes or Indian trust resources.

Our NOI, issued September 13, 2005, described the proposed project, including use of the waterway for LNG marine traffic. The NOI was sent to Indian tribal government leaders and resource agencies, and other Native Americans who may have historically occupied or used the project area, may attach religious or cultural significance to sites in the region, or may be interested in potential project impacts on cultural resources. Copies of the NOI were mailed to the Northwest Regional Office of the U.S. Bureau of Indian Affairs (BIA), CRITFC, Northwest Indian Fisheries Commission, Affiliated Tribes of Northwest Indians, Oregon State Legislative Commission on Indian Services, Washington Governor's Office of Indian Affairs, Confederated Tribes of the Grand Ronde Reservation, Confederated Tribes of the Siletz Reservation, Confederated Tribes of the Warm Springs Reservation, Confederated Tribes of the Umatilla Reservation, Cowlitz Indian Tribe, Chinook Nation, Chehalis Confederated Tribes, Nisqually Tribe, Shoalwater Bay Tribe, Yakama Nation, and Nez Perce Tribe (see table 4.9.3-1). The NOI was also sent to both the Oregon and Washington SHPOs.

In response to our NOI, we received filed written comments about the project from the CRITFC and Nez Perce Tribe. The CRITFC and the Confederated Tribes of the Warm Springs Reservation requested direct consultations with the FERC, and staff made presentations about the project and FERC's review process to the CRITFC on November 17, 2005, and to the Warm Springs Tribal Council on January 24, 2006. Members of the Nez Perce Tribal Council were in attendance during our presentation to the CRITFC. In addition, representatives from the CRITFC and the Nez Perce Tribe attended interagency and public meetings held for this project.

TABLE 4.9.3-1

Native American Consultations for the Bradwood Landing Project

Indian Tribe/Native American Organizations Addressed in the FERC NOI issued September 13, 2005	Date Contacted by NorthernStar	Responses
BIA, Northwest Regional Office, Portland, OR	July 27, 2005 November 28, 2005	September 7, 2007 - commented to the FERC on the draft EIS.
Affiliated Tribes of Northwest Indians, Portland, OR	July 27, 2005 November 28, 2005	December 2, 2005 - Affiliated Tribes of Northwest Indians requested to be informed by NorthernStar of project review status and additional studies.
Oregon Legislative Commission on Indian Services, Salem, OR c/o Karen Quigley, Executive Director	July 27, 2005 November 28, 2005	November 23, 2005 - Commission on Indian Services requested that NorthernStar contact the Siletz and Grand Ronde Tribes.
Confederated Tribes of Grand Ronde, Grand Ronde, OR c/o Cheryle Kennedy, Tribal Chair; and Khani Shultz, Cultural Resources	July 27, 2005 November 28, 2005	August 26 and 30, 2005 – Grande Ronde Tribes requested copies of archaeological survey reports from NorthernStar and to be notified in the event of a discovery during construction.
Confederated Tribes of Siletz, Siletz, OR c/o Delores Pigsley, Tribal Chair; and Robert Kennta, Cultural Resources	July 27, 2005 November 28, 2005	No response documented.
Confederated Tribes of Warm Springs, Warm Springs, OR c/o Olney Patt, Tribal Chair; and Sally Bird, Cultural Resources	July 27, 2005 November 28, 2005	Warm Springs Tribes requested direct consultations with the FERC. January 24, 2006 - FERC staff made presentation to Warm Springs Tribal Council.
Washington Governor's Office of Indian Affairs, Olympia, WA	July 27, 2005 November 28, 2005	No response documented.
Cowlitz Indian Tribe, Longview, WA c/o John Barnett, Tribal Chair; and Mike Iyall, Natural Resources Director	July 27, 2005 November 28, 2005	October 17, 2006 – Cowlitz Indian Tribe wrote a letter to NorthernStar expressing tentative support for the Bradwood Landing Project. Requested that NorthernStar continue to consult with the tribe regarding potential impacts on ecological and cultural resources.
Chinook Nation, Chinook, WA c/o Gary Johnson, Chair	July 27, 2005 November 28, 2005	No response documented.
Chehalis Confederated Tribes, Oakville, WA c/o David Burnett, Tribal Chair	July 27, 2005 November 28, 2005	No response documented.
Nisqually Tribe, Olympia, WA c/o Dorian Sanchez, Tribal Chair	July 27, 2005 November 28, 2005	December 19, 2005 - Nisqually Tribe inquired of NorthernStar if project would be within their territory.
Shoalwater Bay Tribe, Tokeland, WA c/o Chalene Nelson, Tribal Chair	July 27, 2005 November 28, 2005	No response documented.
Yakama Nation, Toppenish, WA c/o Jerry Meninick, Tribal Chair	July 27, 2005 November 28, 2005	No response documented.
Columbia River Inter-Tribal Fish Commission, Portland, OR c/o Olney Patt, Executive Director; and Rob Lothrop	July 27, 2005 November 28, 2005	July 14 and October 17, 2005 - CRITFC sent written comments to the FERC. August 8 and October 26, 2005, and January 25 and September 13, 2006 - CRITFC staff attended interagency and public project meetings. November 17, 2005 - FERC staff made presentation to CRITFC. December 21, 2007 – commented to the FERC on the draft EIS
Northwest Indian Fisheries Commission, Olympia, WA	July 27, 2005 November 28, 2005	No response documented.

TABLE 4.9.3-1 (cont'd)

Native American Consultations for the Bradwood Landing Project

Indian Tribe/Native American Organizations Addressed in the FERC NOI issued September 13, 2005	Date Contacted by NorthernStar	Responses
Confederated Tribes of the Umatilla Reservation, Pendleton, WA c/o Antone Minthorn, Tribal Chair; and Carl Merkle, Natural Resources Nez Perce Tribe, Lapwai, ID c/o Rebecca Miles, Tribal Chair; and Ryan Sedberry, attorney		No response documented. October 17, 2005 - Nez Perce Tribe sent written comments to the FERC. November 17, 2005 - members of Nez Perce Tribal Council attended presentation by FERC staff to CRITFC. January 25 and September 13, 2006 – tribal representatives attended interagency meetings. December 21, 2007 - commented to the FERC on draft EIS.

The Nez Perce Tribe commented on our draft EIS in a letter to the FERC dated December 21, 2007. Among other issues, the tribe requested continued consultations with the FERC, receipt of notices, and invitations to meetings. In a March 12, 2008 email to the FERC's third-party environmental contractor (NRG), an attorney for the Nez Perce Tribe requested that the tribe be invited to the next meeting between the FERC and the NMFS to discuss revisions to the BA and EFH assessment. As an intervenor, the Nez Perce Tribe already receives all notices issued by the FERC for this proceeding. At this time, no additional meetings are planned between the FERC staff and the NMFS. In a February 7, 2008 telephone call between staff and an attorney representing the Nez Perce Tribe, we requested that the tribe provide more specific information about what it wants in terms of the nature of future consultations.

Both the CRITFC and Nez Perce Tribe expressed concern that the project could affect fishery resources protected by tribal treaty rights. In addition, the Nez Perce Tribe raised concerns about the project-related impacts on the lower Columbia River estuary caused by dredging and other activities. This EIS discusses potential impacts on water resources in section 4.3.2, aquatic resources in section 4.5, and federally-listed threatened and endangered salmon species in section 4.6. Indian treaty fishing rights are discussed in section 4.8.1.7.

In letters dated July 27 and November 28, 2005, NorthernStar provided information about the project to Indian tribes and Native American organizations that may have an interest in potential project impacts on cultural resources. The letters were sent to the BIA, Oregon Legislative Commission on Indian Services, Washington Governor's Office of Indian Affairs, CRITFC, Northwest Indian Fisheries Commission, Affiliated Tribes of Northwest Indians, Confederated Tribes of Grand Ronde, Confederated Tribes of Siletz, Confederated Tribes of Warm Springs, Cowlitz Indian Tribe, Chehalis Confederated Tribes, Nisqually Tribe, Shoalwater Bay Tribe, Yakama Nation, and Chinook Tribe.

In response to NorthernStar's consultation program, the Oregon Legislative Commission on Indian Services emailed HRA, NorthernStar's cultural resources contractor, to indicate that the Confederated Tribes of Grand Ronde and Confederated Tribes of Siletz should be contacted about this project. The Confederated Tribes of Grand Ronde requested that HRA provide the tribe with copies of the results of the cultural resources inventories, and the tribe should be contacted if any native archaeological materials are discovered. The Nisqually Tribe contacted HRA to inquire if the project would cross its traditional territory. The Affiliated Tribes of Northwest Indians contacted HRA to obtain more information about the status of the archaeological survey along the pipeline route. In a letter to NorthernStar, dated October 17, 2006, the Cowlitz Indian Tribe expressed tentative support for the project, but requested that NorthernStar continue to consult with the tribe regarding potential impacts on ecological and cultural resources.

Table 4.9.3-1 summarizes consultations with Native Americans. In addition, the FERC provided copies of the draft EIS to Indian tribes and other Native American organizations listed in Appendix A. No traditional cultural properties were identified within the APE by HRA, the SHPOs, Indian tribes, or other Native American organization.

Since the production of the draft EIS for this project, NorthernStar has not documented any additional consultations with Indian tribes. Nor has it documented that it sent copies of the requested cultural resources reports to the Confederated Tribes of Grande Ronde or other interested tribes. Therefore, **we recommend that:**

- **Prior to construction of the LNG terminal and pipeline, NorthernStar should file with the Secretary:**
 - a. **documentation that it re-initiated consultations with all Indian tribes listed on table 4.9.3-1 of the final EIS, and copies of correspondence to and from Indian tribes that expressed interest in its project after the issuance of the draft EIS (in August 2007); and**
 - b. **documentation that it provided copies of revised reports of cultural resources investigations to all Indian tribes that have expressed an interest in the project, including the Confederated Tribes of the Grande Ronde Reservation, and copies of any comments the tribes may have on those reports.**

4.9.4 Compliance with the NHPA

We have fulfilled our obligations to address compliance with the Native American Religious Freedom Act, section 101(d)(6) of the NHPA, and 36 CFR 800.2(c)(2). At our request, NorthernStar documented consultations with Indian tribes and appropriate Native American groups that might have an interest in the project. Through our NOI, we contacted Indian tribes that may have historically occupied or used the project area and might attach religious or cultural significance to historic properties in the APE. No tribe identified any traditional cultural properties which may be affected by the project. Nor were any religious, cultural, or sacred sites that may be affected by the project identified by NorthernStar's cultural resources consultant (HRA), or by the SHPOs.

Under the ACHP's regulations for implementing section 106 of the NHPA, the federal agencies consult with the appropriate SHPOs, identify historic properties, and make determinations of project effects. In a letter dated April 4, 2006, the Oregon SHPO commented on the first draft archaeological survey reports submitted by NorthernStar. The Oregon SHPO agreed with HRA that the project would likely not have an adverse effect on either the LCNHT or the ACRR. We concur.

The Oregon SHPO requested that the draft cultural resources reports be revised to address specific comments. In data requests dated February 9, March 7, and June 30, 2006, the FERC staff also requested revisions to the draft survey reports. NorthernStar filed revised inventory reports on August 21 and November 16, 2006, to address staff and SHPO comments.

In a letter addressed to NorthernStar, dated November 22, 2006, the Oregon SHPO commented on the revised cultural resources survey reports. The Oregon SHPO believes effects on previously recorded site 35CO16 are undefined until additional details about the HDD under the Columbia River are provided. Nor can project effects on the historic Hunt Mill be determined until after NorthernStar provides the results of an archaeological investigation of the old mill location. Lastly, the SHPO questioned the evaluation of the mill town of Bradwood, and requested additional data to support HRA's site assessment.

The Washington SHPO commented on HRA's pipeline survey report in a letter to the FERC dated November 27, 2006. The Washington SHPO requested certain changes to the report, and a plan for future actions, including a schedule for future surveys.

We have not yet completed the process of complying with section 106 of the NHPA for NorthernStar's proposed facilities. Cultural resources surveys for the entire proposed pipeline route and associated ancillary facilities have not been completed because landowner permission has not been

obtained for all parcels. Once cultural resources surveys and evaluations are complete, the FERC, in consultations with the cooperating agencies and the Oregon and Washington SHPOs, will make determinations of NRHP eligibility and project effects. If any historic properties would be affected by the proposed project, we would seek ways to resolve adverse effects.

To ensure that the Commission's responsibilities under the NHPA and its implementing regulations are met, **we recommend that:**

- **NorthernStar should defer construction and use of its proposed facilities, including related ancillary areas for staging, storage, temporary work areas, and new or to-be-improved access roads until:**
 - a. **NorthernStar files with the Secretary all additional required cultural resources survey and evaluation reports, any necessary treatment/avoidance plans, and a cultural resources management plan;**
 - b. **NorthernStar files with the Secretary comments of the Oregon and Washington SHPOs on all cultural resources investigation reports and plans;**
 - c. **the ACHP has been given an opportunity to comment, if any historic properties would be adversely affected by the project; and**
 - d. **the Director of OEP reviews and approves all cultural resources investigation reports and plans, and notifies NorthernStar in writing that treatment plans/mitigation measures may be implemented or construction may proceed.**

All material filed with the Commission containing location, character, and ownership information about cultural resources must have the cover and any relevant pages therein clearly labeled in bold lettering: "CONTAINS PRIVILEGED INFORMATION - DO NOT RELEASE."

4.10 AIR QUALITY AND NOISE

4.10.1 Air Quality

4.10.1.1 Waterway for LNG Marine Traffic

Climate

The proposed waterway for LNG marine traffic would extend from the territorial seas boundary, 12 nautical miles from shore, up the Columbia River to the proposed LNG terminal site at CRM 38. The proposed waterway is within the coastal Columbia River Valley climate region. The climate of the project area is characterized by mild temperatures throughout the year due to the influence of weather systems that have been moderated by traveling over the Pacific Ocean. The normal movement of air masses is from west to east. Rain and drizzle, with fog and low clouds, are frequent from the late fall to early summer months. Warmer, breezy periods with little precipitation are common in the summer and early fall months.

Local winds in the project area generally follow the course of the Columbia River due to terrain effects along the river valley. In the winter, wind speeds reach 20 miles per hour or more about 5 to 10 percent of the time. Visibility is diminished by fog to below 0.5 mile about 3 to 6 days per month. Ice forms occasionally on the river but is seldom heavy enough to affect navigation. Winds during the summer are typically light.

At the mouth of the river, advection fog is common during summer months, with radiation fog affecting the river overall during other months. Precipitation is very common.

Ambient Air Quality Standards

The proposed waterway for LNG marine traffic would pass through both Oregon and Washington. Ambient air quality standards for these states, as well as federal ambient air quality standards, are discussed below

National Ambient Air Quality Standards

The EPA has established National Ambient Air Quality Standards (NAAQS) for seven criteria pollutants: SO₂, CO, nitrogen dioxide (NO₂), ozone, particulate matter less than 10 microns in diameter (PM₁₀), particulate matter less than 2.5 microns in diameter (PM_{2.5}), and lead. The NAAQS were set at levels the EPA believed were necessary to protect human health (primary standards) and human welfare (secondary standards). The NAAQS along with the appropriate Significant Impact Levels (SIL) and relevant estimated background concentrations for the project area are listed in table 4.10.1-1. Most ambient background concentrations were provided by the ODEQ on January 4, 2006 (CO and NO₂) and March 8, 2006 (PM₁₀ and SO₂). In addition, ambient background concentrations for ozone are based on monitoring data collected at Sauvie Island, Oregon.

State Ambient Air Quality Standards: Oregon

For most criteria pollutants, Oregon Ambient Air Quality Standards (OAAQS) are the same as federal NAAQS. However, Oregon has set more stringent standards for SO₂. The Oregon SO₂ standards (in ppm) and equivalent concentrations in µg/m³ are shown in table 4.10.1-2.

TABLE 4.10.1-1						
National Ambient Air Quality Standards						
Air Pollutant	Averaging Period	Background Level	Primary Standard	Secondary Standard	Percent of Primary NAAQS	SIL for NAAQS
SO ₂ (µg/m ³)	3-Hour ^a	65	NA	1,300	NA	25
	24-Hour ^a	30	365	NA	0.08	5
	Annual ^b	5	80	NA	0.06	1
CO (µg/m ³)	1-Hour ^a	2,000	40,000	NA	0.05	2,000
	8-Hour ^a	1,400	10,000	NA	0.14	500
NO ₂ (µg/m ³)	Annual ^b	15	100	100	0.15	1
Ozone (ppm)	1-Hour ^a	0.077	0.12	0.12	0.64	NA
	8-Hour ^c	0.061	0.08	0.08	0.76	NA
PM ₁₀ (µg/m ³)	24-Hour ^a	30	150	150	0.20	5 (1.0 in Oregon)
	Annual ^b	15	50 ^f	50 ^f	0.31	1 (0.2 in Oregon)
PM _{2.5} (µg/m ³)	24-Hour ^d	NA	35	35	NA	NA
	Annual ^b	NA	15	15	NA	NA
Lead ^e	NA	NA	NA	NA	NA	NA
^a The second highest designation indicates that the concentration listed is representative of the second highest concentration measured at the monitoring station. ^b The annual average concentration. ^c The fourth highest designation indicates that the concentration listed is representative of the fourth highest concentration measured at the monitoring station. ^d The 98th percentile 24-hour concentration. ^e Lead is not monitored in Oregon or Washington. ^f The historical annual PM ₁₀ NAAQS was revoked, effective December 18, 2006. µg/m ³ micrograms per cubic meter						

TABLE 4.10.1-2		
Oregon SO ₂ Ambient Air Quality Standards		
Averaging Period	Oregon Standards	
	Ppm	Equivalent µg/m ³
1-Hour ^a	NA	NA
1-Hour ^b	NA	NA
3-Hour ^a	0.50	1,300
24-Hour ^a	0.10	260
Annual ^a	0.020	52
^a Not to be exceeded more than once per calendar year. ^b Not to be exceeded more than twice per 7-day period.		

State Ambient Air Quality Standards: Washington

For most criteria pollutants, Washington Ambient Air Quality Standards (WAAQS) are the same as federal NAAQS. However, Washington has standards for total suspended particulates (TSP) and has set more stringent standards for SO₂. The Washington TSP and SO₂ standards (in ppm) and equivalent concentrations in µg/m³ are shown in table 4.10.1-3.

TABLE 4.10.1-3			
Washington TSP and SO ₂ Ambient Air Quality Standards			
Averaging Period	TSP Standards		SO ₂ Standards
	µg/m ³	ppm	Equivalent µg/m ³
1-Hour ^a	NA	0.40	NA
1-Hour ^b	NA	0.25	NA
3-Hour ^a	NA	NA	NA
24-Hour ^a	150	0.10	260
Annual ^a	60	0.020	52
^a	Not to be exceeded more than once per calendar year.		
^b	Not to be exceeded more than twice per 7-day period.		

Existing Air Quality

The counties along the proposed waterway for LNG marine traffic are Clatsop County in Oregon and Wahkiakum and Pacific Counties in Washington. These counties are currently designated as attainment or unclassifiable for all NAAQS criteria pollutants. Marine vessels are a primary source of air pollution, with a secondary contribution from nearby industrial facilities. Operation of the proposed project would result in additional marine vessel emissions from the arriving and departing LNG carriers as well as supporting tug boats and escort boats.

Air Quality Control Regions

Air Quality Control Regions (AQCR) were established by the EPA and local agencies, in accordance with section 107 of the CAA, as a means to implement the CAA and comply with the NAAQS through state implementation plans. The AQCRs are intra- and interstate regions such as large metropolitan areas where the improvement of the air quality in one portion of the AQCR requires emission reductions throughout the AQCR. The counties crossed by the project's marine traffic along the proposed waterway are Clatsop County, Oregon, which is in the Northwest Oregon Intrastate AQCR (40 CFR 81.249); Wahkiakum County, Washington, which is in the Portland Interstate AQCR (40 CFR 81.51); and Pacific County, Washington, which is in the Olympic-Northwest Washington Intrastate AQCR (40 CFR 81.187).

Regulatory Requirements for Air Quality

The entire LNG marine transit route is an attainment area and therefore not subject to a General Conformity determination. LNG carriers are mobile sources and thus not subject to permitting under the CAA.

Air Quality Impacts and Mitigation

LNG carriers are mobile sources that transit the Pacific Ocean. As the LNG carriers enter the waterway, they would be assisted by two tugboats and a waterside security escort during their journey along the Columbia River. Estimated criteria and GHG emissions from LNG carriers, tugs, and security vessels are summarized in tables 4.10.1-4 and 4.10.1-5.

TABLE 4.10.1-4								
Estimated Air Emissions from the LNG Carriers, Tugs, and Security Vessels (PM ₁₀ , SO ₂ , NO _x , and CO)								
Source	PM ₁₀		SO ₂ ^a		NO _x		CO	
	maximum lb/hr	Tpy	maximum lb/hr	tpy	maximum lb/hr	tpy	maximum lb/hr	Tpy
Security Vessels ^b	0.1	0.1	0.0	0.0	0.5	0.3	1.2	1.2
Tugs ^c	4.4	5.2	1.3	1.6	175.6	209.6	21.2	24.8
LNG Carriers ^d	17.8	7.0	1,630.1	644.6	706.4	278.9	106.5	43.4
Total	22.8	12.8	1,641.1	655.0	894.6	499.8	135.7	75.6
^a The SO ₂ emissions from the LNG carriers are based on an estimated fuel sulfur content of 4.5 weight percent for ship main engines and generators in transit. Emissions from LNG carriers at berth are based on burning bog with a side stream of liquid fuel. ^b Emissions from security vessels are based on those vessels utilizing gasoline-powered outboard motors. Two security vessels would accompany each LNG carrier to/from berth to Astoria. One security vessel would be on standby during docking while the LNG carrier is in port. ^c Emissions from tugs providing both upriver and downriver LNG carrier support estimated assuming the tugs would be based in Longview. Two tugs would escort each LNG carrier from Buoy 10 to port. A third additional tug would travel from Longview to the Bradwood Landing Terminal to provide berthing/unberthing support. ^d Emissions from LNG carriers in transit include both upriver and downriver operations.								

TABLE 4.10.1-5							
Estimated Air Emissions from the LNG Carriers, Tugs, and Security Vessels (VOCs, CO ₂ , and CH ₄)							
Source	VOCs		CO ₂		CH ₄ ^a		Tpy
	lb/hr	lb/hr	lb/hr	tpy	lb/hr	tpy	
Security Vessels ^b	2.8	2.2	971	986	--	--	
Tugs ^c	2.1	2.4	11,768	14,028	--	--	
LNG Carriers (transit) ^d	11.9	5.1	46,066	19,007	--	--	
LNG carriers (at berth)	2.8	2.6	3,065	2,785	20.0	18.2	
Total	19.6	12.3	61,870	36,806	20.0	18.2	
^a Emission factors of CH ₄ from the combustion of liquid fuel in ship engines are not available and have therefore been assumed to be negligible. ^b Emissions from security vessels are based on those vessels utilizing gasoline-powered outboard motors. Two security vessels would accompany each the LNG carrier to/from berth to Astoria. One security vessel would be on standby during docking while the LNG carrier is in port. ^c Emissions from tugs providing both upriver and downriver LNG carrier support estimated assuming the tugs would be based in Longview. Two tugs would escort the LNG carrier from Buoy 10 to port. A third additional tug would travel from Longview to the Bradwood Landing terminal to provide berthing/unberthing support. ^d Emissions from LNG carriers in transit include both upriver and downriver operations.							

Emission estimates are based on transit between entry into U.S. waters (approximately 24 nautical miles beyond the mouth of the Columbia River) and the proposed Bradwood Landing terminal, and assume slow cruise speeds and maneuvering speeds. The ships used to transport LNG to and from the LNG terminal would be under the jurisdiction of the Coast Guard, which has the authority to dictate ship speed and navigation.

Ships are anticipated to deliver LNG to the proposed terminal approximately 125 times per year, with each delivery lasting up to 24 hours. Due to the limited number of ships and the short time frame of each visit, LNG carriers are expected to be present at the terminal approximately 34 percent of the year. Receptors close to the LNG carrier route may experience elevated levels of regulated pollutants.

Although the emissions from marine vessel traffic are large, the emissions would be periodic and transient. Therefore we do not expect regionally significant air quality impacts would occur.

NorthernStar completed an air dispersion modeling analysis of the LNG carrier emissions from the on-board electrical generator during hotelling operations (Bradwood Landing Evaluation of AAQS and Prevention of Significant Deterioration (PSD) Increment Consumption from LNG Carrier Vessel Emissions during Offloading, July 13, 2006). Using an EPA-approved dispersion model, impacts of criteria pollutants from the LNG carriers plus the preliminary modeled impacts from the LNG terminal, competing sources, and background concentrations were added together and compared to the applicable federal NAAQS and Prevention of Significant Deterioration (PSD) Increments. Detailed results are presented in section 4.10.1.2.

If a marine LNG spill occurred, any unignited LNG would vaporize; because LNG is mostly composed of methane. No criteria air pollutants would be associated with the vaporized LNG. However, methane is considered a GHG and may contribute to global warming. The dispersion of the methane vapors would cause a temporary decrease in the ambient air quality. Wildlife and humans occupying the water's surface near the release could intercept the vapor cloud prior to dispersion and suffer asphyxiation. The duration of exposure to any substantial pollutant concentrations would be short and would not pose a significant health risk to sensitive receptors given the distance to shore from a potential LNG spill. Therefore, there would be no significant impacts on air quality in the unlikely event of a marine LNG spill.

However, if ignition to the vapor cloud would occur, combustion emissions would be released to the atmosphere. Natural gas combustion typically is not complete in spill scenarios. The products of incomplete combustion of natural gas include criteria pollutants, hazardous air pollutants, unburned hydrocarbons, and soot (carbon particulates). The maximum increases in ambient air pollutant concentrations due to the natural gas vapor cloud fire would occur downwind of the LNG spill. These ambient air pollutant concentrations would likely exceed short-term NAAQS and State Ambient Air Quality Standards over the duration of the fire as well as soot deposition and diminished visibility due to soot transport. In the more populated areas of the transit route receptors would be exposed to higher pollutant concentrations for the short duration of the fire. The types and amounts of emissions from the ignition of an LNG pool would depend on many factors, but the emissions to any one localized area would be temporary and depend on weather and other conditions along the waterway. Emissions at a particular location that would arise from ignited vegetation and any nearby man-made structures would likely have greater levels of unburned hydrocarbons and hazardous air pollutants. Any acute exposures to smoke from LNG and induced fires may lead to range of problems such as a worsening of asthma conditions, irritation of the eyes, nose and throat, and difficulty breathing. In sensitive populations (children, elderly, chronically ill) symptoms of exposure may be of greater magnitude.

4.10.1.2 LNG Terminal

Climate

The proposed Bradwood Landing LNG terminal would be located in Clatsop County, Oregon, within the coastal Columbia River Valley climate region, described in section 4.10.1.1. Clatsop County is one of the six counties designated as the Northwest Region by the ODEQ.

The National Weather Service (NWS) maintains a climate station at the Astoria Regional Airport in Astoria, Oregon, located in Clatsop County and the Kelso-Longview Regional Airport in Cowlitz County, Washington. Climate data from these stations are available from the Western Regional Climate

Center from January 1, 1899 to the present. These data should be representative of conditions in the area of the proposed terminal.

Ambient Air Quality Standards

The federal and Oregon ambient air quality standards applicable to this portion of the project are discussed in 4.10.1.1 above.

Existing Air Quality

Clatsop County is currently designated as attainment or unclassifiable for all NAAQS criteria pollutants. Motor vehicles are a primary source of air pollution, with large industrial facilities accounting for less than 15 percent of most types of criteria pollutants. Other sources of air pollution include human activities such as outdoor burning, using wood stoves, and using non-road vehicles (e.g., gasoline-powered lawn mowers, motor boats, etc.).

Construction of the proposed terminal would cause temporary combustion emissions associated with operating construction equipment and vehicles. Fugitive dust would also be generated by site preparation activities and equipment travel. These emissions would occur during the projected 36-month construction period. The bulk of long-term emissions for the Bradwood Landing Project would be emitted from stationary sources at the proposed LNG terminal.

Air Quality Control Regions

The Bradwood Landing LNG terminal would be located in the Northwest Oregon Intrastate AQCR (40 CFR 81.249).

Regulatory Requirements for Air Quality

Emissions from all phases of construction and operation of the proposed LNG terminal would be subject to applicable state and federal air regulations. Most air quality regulatory programs address emissions from stationary sources of air pollution; these programs would primarily affect ongoing operations at the proposed LNG terminal. Air quality regulations affecting LNG terminal construction are primarily concerned with reducing emissions associated with construction equipment and fugitive dust.

The new stationary air emission sources associated with operating the proposed LNG terminal include seven SCVs, one emergency generator, and one diesel firewater pump. These stationary sources are listed in table 4.10.1-6.

TABLE 4.10.1-6			
Stationary Source Information			
Air Emission Source (quantity)	Heat Rating (MMBtu/hr)	Horsepower Rating (bhp)	Energy Source
SCVs (7)	120 (each)	NA	Natural Gas
Emergency Generator (1)	5.52	1075	Diesel Fuel
Emergency Firewater Pump (1)	1.21	405	Diesel Fuel
bhp	brake horsepower		
MMBtu/hr	million British thermal units per hour		

The proposed terminal air emission sources are regulated at the federal level by the CAA, as amended, and at the state level by OAR. In addition to state regulations, the federal regulations established as a result of the CAA that are potentially applicable to the project include:

- Mobile Source Regulations;
- New Source Performance Standards (NSPS);
- PSD review or nonattainment New Source Review;
- Nonattainment New Source Review;
- Title V Operating Permits;
- National Emission Standards for Hazardous Air Pollutants (NESHAP);
- Federal Class I Area Protection;
- General Conformity; and
- Chemical Accident Prevention.

Federal Air Quality Requirements

Mobile Source Regulations

Title II of the CAA Amendments of 1990 – These regulations contain provisions relating to highway and off-road mobile sources and are aimed at reducing pollution from heavy-duty diesel engines, including marine and locomotive engines.

40 CFR 69, 80, and 86, Final Rule, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements – This rule requires a reduction in emissions from on-road diesel engines and establishes sulfur limits for diesel fuel. Currently, the requirements are for new engines only and the standards will begin to take effect in model year 2007. Although the emissions standards are for new engines only, the reduced sulfur diesel fuel, which is required to have a sulfur content less than 0.05 percent (500 parts per million by weight (ppmw)), a limit that was lowered to 15 ppmw starting in June 2006, would also reduce particulate and SO_x emissions from existing diesel engines.

40 CFR 9 and 69 et al., Final Rule, Control of Emissions of Air Pollution from Non-road Diesel Engines and Fuel – This rule requires emissions reductions from non-road diesel engines by establishing emissions limits and sulfur content limits. This rule targets agricultural equipment, construction equipment, and other non-road diesel engines. As with the previous rule, the reduced sulfur fuel would lower emissions from existing diesel engines even though the emissions limits would only apply to new engines.

Both non-road and highway use vehicles and construction equipment used for the project would be required to use the new low sulfur diesel fuel as soon as it is commercially available.

New Source Performance Standards

NSPS regulations (40 CFR 60) establish pollutant emission limits and monitoring, reporting, and recordkeeping requirements for various emission sources based on source type and size. The NSPS apply to new, modified, or reconstructed sources.

Subpart Db of 40 CFR 60 applies to industrial, commercial, or institutional steam generating units that are modified, constructed, or reconstructed after June 19, 1984 and have maximum heat input rates of more than 29 MW or 100 million British thermal units per hour (MMBtu/hr). Subpart Db establishes specific emissions limits for SO₂ (for coal and oil fired units) and PM (for coal fired units). The SCVs

proposed for this project would be designed to have direct contact and intermixing of the combustion gases and the heat transfer medium, and available EPA guidance states that these units should not be considered “steam generating units;” therefore, the requirements of NSPS Db do not apply.

Subpart Kb of 40 CFR 60 applies to any volatile organic liquid storage unit that is modified, constructed, or reconstructed after July 23, 1984 and that has a capacity of 40 m³ or greater. Subpart Kb exempts large tanks that store a liquid with a maximum true vapor pressure of less than 3.5 kilopascals (kPa). The two LNG storage tanks at the proposed terminal would each have a nominal capacity of 160,000 m³ and store liquids with a maximum true vapor pressure of less than 3.5 kPa based on the maximum pressure expected during the warmest calendar month. Consequently, the LNG storage tanks would not be subject to Subpart Kb.

Subpart IIII of 40 CFR 60 applies to stationary compression ignition internal combustion engines that are modified, constructed, or reconstructed after July 11, 2005. The emergency generator and fire pump engine would be subject to this regulation. The manufacturers of post-2007 units must certify that the engines would comply with the standards for the useful life of the engine. The Bradwood Landing Project emergency engines would be ordered after 2008 and would comply with these standards.

Prevention of Significant Deterioration

Title I of the CAA establishes guidelines for the preconstruction/modification review of large air emission sources. Construction of sources in attainment areas must be reviewed in accordance with the PSD regulations. To be classified as a new major PSD source, the potential emissions from the source must be: either greater than 100 tons per year (tpy) for any pollutant regulated by the EPA under the CAA for sources that are among the 28 source categories listed in section 169 of the CAA, or greater than 250 tpy for any pollutant regulated by the EPA under the CAA for sources that are not among the 28 source categories listed in section 169 of the CAA. A BACT analysis and detailed dispersion modeling are required if a facility is classified as a major PSD source.

The applicability threshold for PSD review for the proposed LNG terminal is 250 tpy, based upon a determination by the ODEQ that the facility does not include any sources among the 28 listed source categories. Tables 4.10.1-7 and 4.10.1-8 present the annual maximum potential criteria pollutant and GHG emissions from the proposed LNG terminal and relevant PSD threshold criteria. We have removed lead from the list of criteria pollutants because emissions of lead from the SCVs and from fugitive emission leaks would be zero due to an absence of lead contamination in the vaporized LNG.

As shown in tables 4.10.1-7 and 4.10.1-8, the maximum emissions from the proposed LNG terminal would be less than 250 tpy for each of the criteria pollutants. Therefore, the proposed LNG terminal would not be a federal major source and would not be subject to PSD review.

Nonattainment New Source Review

Title I of the CAA establishes guidelines for the preconstruction/modification review of large air emission sources. Construction of sources in nonattainment areas must be reviewed in accordance with the New Source Review regulations. As discussed above for the waterway and LNG terminal and in section 4.10.1.3 for the pipeline, the entire project area is located in attainment or unclassifiable areas. Consequently, nonattainment New Source Review does not apply to this project.

TABLE 4.10.1-7								
Operating Air Emissions Summary for Proposed LNG Terminal (NO _x , CO, SO ₂ , and PM ₁₀ /PM _{2.5}) ^a								
Emission Unit (Quantity)	NO _x		CO		SO ₂		PM ₁₀ /PM _{2.5}

^b	Maximum hourly emissions.						
^c	The calculations for the SCVs assume seven heaters operating at maximum capacity (120 MMBtu/hour/unit).						
^d	Emergency generator and firewater pump potential emissions calculations based on 52-hour-per-year operation.						
^e	Total emission rates in lb/hr assume that the firewater pump and emergency generator are both operating.						
^f	Emissions of CO ₂ from the SCVs are based on a terminal sendout rate of 1 Bscfd and assuming 1.31% of the sendout (26,000 lbs/hr of natural gas) is used to fuel the SCVs during the vaporization process.						
NE	not estimated						
NA	not applicable						

Title V Operating Permits

Title V of the CAA requires states to establish an air operating permit program. The requirements of Title V are outlined in 40 CFR 70 and the permits required by these regulations are often referred to as Part 70 permits. The EPA has delegated the authority to issue Part 70 permits to the ODEQ. Part 70 permit program requirements are codified in OAR 340-218 and fee requirements are codified in OAR 340-220.

If a facility's potential to emit exceeds the criteria pollutant or hazardous air pollutant (HAP) thresholds, the facility is considered a Title V major source. Under Part 70, the major source threshold

for an air emission source in Oregon is 100 tpy for PM₁₀, PM_{2.5}, SO₂, CO, NO_x, VOCs, or lead. As shown in tables 4.10.1-4 and 4.10.1-5, the potential emissions for NO₂ (the primary component of NO_x) and CO at the proposed LNG terminal exceed 100 tpy. Therefore, the LNG terminal would be a major source of air emissions and would require a Part 70 permit.

The Title V major source HAP thresholds for a source are 10 tpy of any single HAP or 25 tpy of all HAPs in aggregate. Potential HAP emissions from the proposed LNG terminal (in aggregate) would be 6.94 tpy from stationary sources, which are below the major source thresholds.

National Emission Standards for Hazardous Air Pollutants

The NESHAPs, codified in 40 CFR 61 and 63, regulate HAP emissions. Part 61 was promulgated prior to the 1990 Clean Air Act Amendments (CAAA) and regulates only eight types of hazardous substances (asbestos, benzene, beryllium, coke oven emissions, inorganic arsenic, mercury, radionuclides, and vinyl chloride).

The 1990 CAAA established a list of 189 HAPs; resulting in the promulgation of Part 63. Part 63, also known as the Maximum Achievable Control Technology (MACT) standards, regulates HAP emissions from major sources of HAP emissions and specific source categories that emit HAPs. Part 63 defines a major source of HAPs as any source that has the potential to emit 10 tpy of any single HAP or 25 tpy of HAPs in aggregate.

LNG storage and processing facilities are not one of the source categories regulated by Part 61; therefore, the requirements of Part 61 are not applicable to the proposed facility. Part 63 establishes HAP emission standards for marine vessel loading operations (Subpart Y); oil and gas production facilities (Subpart HH); natural gas transmission and storage facilities (Subpart HHH); industrial, commercial, and institutional boilers and process heaters (Subpart DDDDD); and reciprocating internal combustion engines (Subpart ZZZZ). These subparts establish requirements for major sources of HAPs only. As indicated above, the potential HAP emissions (in aggregate) from LNG terminal stationary sources would be 6.94 tpy. The single largest HAP emitted by the terminal would be hexane with a potential to emit of 6.49 tpy. Therefore, the LNG facility would not be a major source of HAPs and would not be subject to the NESHAPs.

Federal Class I Area Protection

The U.S. Congress designated certain lands as Mandatory Federal Class I (Class I) areas in 1977. Class I areas were designated because the air quality was considered a special feature of the area (e.g., national parks or wilderness area). These Class I areas, and any other areas that have been redesignated Class I areas since 1977, are given special protection under the PSD program. The PSD program establishes air pollution increment increases that are allowed by new or modified air pollution sources. If the new stationary source is required to comply with PSD program requirements and is near a Class I area, the source is required to determine its impacts at the nearby Class I area(s). The source is also required to notify the appropriate federal land manager(s) for the nearby Class I area(s).

As explained previously, the proposed LNG terminal would not be subject to PSD regulations. The proposed pipeline also would not be subject to PSD regulations. Therefore, federal Class I area protection provisions would not apply to this project; however, impacts on Class I areas are discussed below and shown in table 4.10.1-12.

General Conformity

A conformity analysis must be conducted if a federal action will generate emissions that will exceed the conformity thresholds levels (*de minimis*) of the pollutant(s) for which an air basin is designated as a nonattainment area or a maintenance area. Because the project area would not be located in a nonattainment or maintenance area, general conformity would not apply to the Bradwood Landing project.

Chemical Accident Prevention
